PRINTED AT THE JOURNAL OF HORTICULTURE OFFICE,
171, FLEET STREET.

TO OUR READERS.

IN some work of fiction—"Abel Abhut," if we remember correctly—an old lady by way of variety wore her cap reversed, or "behind before," as is said in the nursery regions. The plan was simple, and we were tempted to adopt it on the present occasion: not literally, by so wearing our caps, but by copying a preface to one of our ancient volumes, putting some of the last sentences first, and some of the first sentences last; and one of us—for you know we are dual—suggested the proceeding, but the other gravely shook his head. The suggester rejoined, "There's nothing new to say, you know." Still the grave one shook his head. "Instead of shaking your head," retorted the suggester, "shake something out of it that will do for a preface: I've tried without success." This reply was elicited: "A gentleman proposed marriage to a damsel; her father wrote a refusal, but in the damsel's handwriting on the envelope was written 'STRIPES.' Let us take the advice contained in that word."

We did so, and we will do so to the end of our career. That word transposed is "PERSIST." We have persisted, and have almost written already enough for an address to you—"our Readers." We will persist in the course we have hitherto succeeded in pursuing, and that will enable us to persist in pleasing you. We will persist in the endeavour to establish truth in all that appertains to our various departments. We will persist in linking our arms through the arms of old contributors, and in holding out the hand of welcome to new ones. We will persist in gratefully accepting information, and in courteously imparting that which we possess.

INDEX.

AMSTERDAM POULTRY SHOW, 58
Ayrington Poultry Show, 284
Achimenes—watering, 243; select, 174
Agaveus fimeatarius, 396
Air-giving, 156, 459
Allamandas—Schottii, 117; starting, 191
Alloplectus capitatus culture, 340
Amaryllis—culture, 277; Prince Teck, 296
Amateurs, hints for, 21
American plants—managing, 394; Waterer & Godfrey's, 408; at Regent's Park, 408
Ammoniacal liquor, vaporising with, 366; for Vines, 427
Andalusian fowl's merits, 231
Anemones—management of seedling, 316; single, 371
Annals—sowing half-hardy, 299; to bloom in October, 412
Anthrium Scherzerianum culture, 356
Ants—in a greenhouse, 157, 345; on a lawn, 229; banishing, 284; destroying, 327
Apeliandra Porteana culture, 381
Aphides—destroying, 355; on fruit trees, 386
**Apples—for espaliers, 33; trees mossy, maggots in, 80; training, 157; grafting, 262; for a trellis, 191; shoots diseased, 244; late kitchen, 301; Reinette, 460; budding, 460
**Apricots—on walls, 281; ripening of orchard house, 453
April, plants flowered in, 342
Aquarium, fish failing in, 122
Aquatic plants for ponds, 54
Araucaria—Cunninghamii siuensis, 91, 156; imbricata, 243
Arbutus propagation, 244
Arcade, evergreen for, 109
Aristolochia ringens, 296
Arnott's stove, 133, 157; experience with, 27; for heating, 91
Arums, removing flower stems, 348
Asparagus—culture, 22, 45; French, 280; beds, salting, 174; from seed, 229; planting, 244; in damp soil, 263; planting and manuring, 361
Asphalted root, water from, 32
Asphalt garden walks, 300
Ataccia cristata, 342
Aucuba japonica, 181, 199; berries, gathering and sowing, 229; sowing, 298; propagation, 257; grafting male on female, 316; berries, 360
Auriculas—why are they neglected? 235; culture and list, 290; Colonel Champeys, 342; season for showing, 361; potting early, 390; potting, 456; sowing, 446
Azaleas—shoots, stopping, 101; varying, 191; over-potted, 283; culture, 414
BAG-HOLDER AND TUNNEL COMBINED, 274
Bait, poisoned, 226
Balsams to flower in August, 331
Bamboo planting, 283
Banksia and Grexvillea cuttings, 380
Banant culture, 396
Banalore Horticultural Fête, 257
**Bantams—varieties of Black, 88; plumage of Game, 106; dubbing Game, 122; weak-legged, 268; chickens, 416; carbones of Black Red, 166
Barbie de Capcon, 380
Barndoor fowls, 246
Barbore plants for in a greenhouse, 118; for suspended, 229
Bath and West of England Society, 119; Poultry Show, 412******

Beans, sowing, 134
**Bedding plants, 379; that winter in a cold pit, 5; in a pit, 80, 118; yellow, 106; hardening-off, 260, 263; for early and late planting out, 336, 357
Bedington Poultry Show, 430
Beck-keeping, Frothdale, 329
**Bees—foul brood; Ligurian queen raising, 19; doings in a small apiary in 1867, 38, 63; honey harvest of 1867, cheap hives, Ligurians, 64; utilising and uniting condemned, 87; bars for supers, gratings to exclude drones, nucleus hives, combs beyond bars, 88; utilising and uniting condemned, 105; decreasing; hives, changing floor-boards, cork for, 106; utilising and uniting condemned, 121; feeding, dead ejected, bar-frame hive, 122; an American apiary, 145; flower for, 146; saving condemned, feeding, 146; uniting condemned, food for, management, 162; improved cottage hive for, strange phenomenon in, price of Ligurian and of frame hives, 178; artificial swarming in common hives, 179; flowers for, 180; adding Ligurian queens, 195; who introduced Ligurians successfully, 196; effects of foul brood, 196; house, removing, excrement of, hives, driving, 196; utilising condemned, 215; distance of flight, artificial swarming in common hives, transferring, forming an artificial swarm, 216; consequences of mismanagement, 231; neglecting food, pruning combs, forming artificial swarm in unicorn hive, 232; Ligurian queen's wing torn, 250; early drones, 251; hive covers, 252; consequences of mismanagement, shifting into a new hive, 267; comb-construction in Woodbury hives, hives, aspect for bee house, Ligurianising, hives containing empty combs, 268; artificial swarming, feeding, falling, 288; Egyptian in America, 394; Abyssinian, 395; hives, diving, feeding, 396; painting straw hives, utilising and uniting condemned, 397; early swarms, 320; varieties in Ceylon, super left on a hive, hives turpentine, Buckwheat as a bee flower, 384; unjust slaughter, 352; how to breed pure queens, procuring artificial swarming, frame hives, 359; early drones, 354; effects of chill on undeveloped brood, management of, 369; breeding Ligurians, Kochler's discovery, temporary support of combs, adding queens, American collateral plan, 387; queen's fecundity, culture to supers, 399; strong v. weak swarms, 415; feeding confined, 416; capping a hive, 416; strong versus weak swarms, raising queens, 431; removing hive to bee house, 432; hive, 449; driving, weak v. oak, feeding confined, 450; artificial swarming in common hives, German centrifugal hive-extracting machine, 465; improved wax-melting apparatus, not swarming, 466
Bee Red, varieties of, 136; as a flower-garden plant, as a desert ornament, 369; as a bedding plant, 365
**Begonias—Veitchii and rosa-flora, 71; fine-foliated, 80; glandulifera, 239; falcifolia, 342; Sutherlandii, 170
Belladonna Lilies, 255
Blepharidopsis corallina culture, 445
Berry Hill, 26
Bignonia jasminoides not flowering, 54
Bird's-nest Fern blackened, 381******

Birds v. fruit buds, 111
Birmingham Poultry Show, 332
Bizchia sapida culture, 229
**Boilers, 224, 271, 395; setting a saddle-back, 100; Marriott's, 127; portable, 282; for stoves, 308
Bone dust for lawn, 191
**Bonnie—dissolving, 11; by potash, 73
Books for a young gardener, 117
Box-er flowers, neglected, 341
**Borecole—Melville's Improved Variegated, 167; as a dessert ornament, 360
Botanical specimens, drying, 78
**Botanic (Royal) Society's Shows, 330, 401, 430
Bottom heat, hot water for, 245
Bougainvillea glabra, flowering of, 380; spectabilis, 117
Bouquets, to make skeleton, 456
**Box—propagation, 101; edging, clipping, 392
**Brahm Pootras—separate prizes for, 16, 102; Light and Dark, 82, 120, 143, 158, 175, 245; plumage of dark cock, confined, 88; plumage of Dark, 106; points, 180; versus Hamburgs, 113; merits of, 141; classes, 193; management, 194; bearing down in, 196; Light, 212; combs, 216; cross with Dorkings, 246; breeding Dark, 252; and Dorkings, 264; web-footed, 268; chickens' wings twisted, 288; chickens, growth of, 384; Light v. Dark, 398; prizes, 462
Breaking-up common land, 283
Brussels, crooked, 88
British Flowering plants, 453
**Broccoli—not true, 95; late, 388; large, 408
Broom, cutting-in, 428
Brussels sprouts culture, 89
**Buckwheat—sowing, 192; for poultry, 232, 284, 303, 352, 416
Buckwheat's stamens, style for, 365
Bulbs after flowering, 265
**Bullfinches—breeding, 136; materials for nest, 252; coughing, 116
Rush training, 198
**Butter—sending by rail, 146; becoming rank, 384
CAULI INFESTED BY SCALE, 245; pruning, 301; not flowering, 428
Calabar Bean, 282
Caladiums—potting, 141; culture, 253
Calanthe vestita culture, 395
Calceolarias, herbaceous, cuttings, 101; failing, 349
Caledonian (Royal) Horticultural Society's shows, 170
Callistemon lanceolatus propagating, 262
Cambridge Poultry Show, 159
**Camellias—select, 33; bloom buds falling, leaves sticky, 54; culture, 141, 291, 276; aphides on, 290; training, 348; Madame Ambrose Verschaffelt, 423; in pots and borders, 441; house for, 115; not flowering, 460
Canada, notes in, 8
**Canaries, 63, 150; lice in cage, 88; with lark, detecting sex, 105; nest-mate and laid, 116; stamping, bleeding, 122; breeding, a guide to, 135, 231, 266, 297, 333, 398, 399; Lizard, 281, 249; singing, 232; Goldfinch Mules, 267; Lizard, are hybrids fruitful? 319; hen while sitting, 334; eating their eggs, 400; breeding Norwich, 430; long-clawed, 116
Canary Club project, 86
**Canker in fruit trees, 118, 383
Cannas, culture, for small garden, 118
Cantua boxifolia culture, 316
Canvas protection for wall trees, 229**************************

Caponising, 409
Carboic acid, 376, 437
Carrots, boiled for fowls, 156
Carter & Co.'s Nursery, 74
**Caterpillars on bedding plants, 91, 124, 167, 294; on Pelargoniums, 149, 158
Cattleya am-thyroglossa, 71
Cauliflower culture, 238
Cautions to purchasers, 350
Cedrus, the genus, 102
Celeriac culture, 330
Celery, Henderson's Conqueror, 94
Celosias to flower in August, 330
**Centaurea—candidissima from seed, 117; culture, 164, 267; propagation, 137, 219; its merits and defects, 254; propagation and failure, 292; ragusina propagation, 118
**Cerastium tomentosum—edging, 15; cuttings, 262
Chamaecyparis humilis, transplanting, 210
**Charcoal—ashes for manure, 55; for composts, 174
Chatsworth, new gardener at, 296
**Cherries—trees decaying, 263; caterpillars on, 316; ripening of orchard house, 453; falling, 461
Chickenhood, 363
**Chickens—fattening, 162; marking, 216, 320; spring, 232; payment for rearing, 257; checking growth of, 288; rearing spring, 318; rearing, 349; promoting growth of, deformed, 354; dying in the shells, 396; weak-footed, 490; malformed, 493; fattening spring, 384; dying, 416
Christmas Rose planting, 261
**Chrysanthemums—propagating, 80; to a greenhouse, 118
**Churchyard—shrubs, 15; planting, 130
Cider as a test of Apples, 325
**Cinerarias—losing flower stems, 33; flowers petalless, 80; culture, 141; potting, 174
Clarke, Major T., medal to, 126
Ceanothus Dampieri, duration of, 380
**Clay, burning, 141
**Clematises—for training on trees, 80; pruning, 428
Clerodendron Thomsomii, 117
Clianthus Dampieri training, 161
**Climbers—pruning, 31; for stove, 33; for north aspect, 243; for greenhouse and conservatory pillars, 283; in-door, 463; for eastern aspect, 428
Cloche, the, 167
**Cloberry, 401
Coal, economy in, 116
Coburgia trichroma, 71
Coccoloba platyclada for table decoration, 104
**Cochin-Chinas—judging, 81; scurfy legged, 122; huckle of Cinnamon hen, 180; legs, scurf on, hooks of, 216; cock's head swollen, 252, 288; meat for, 252; colour of eggs, 268; chickens dying in the shell, 320
Cockards and pullets, separating, 396
Cochlostoma Jacobianum, 312
Cockscom culture, 237
**Cocks fighting, not growing, 416
Cologne cristata culture, 210
Cola acuminata, 239
**"Coleoptera Hesperiidae," 238
**Colusae, sale of, 237, 312
Colinsia verna, 371
**Colocasia esculenta, motions, 337
**Combs—fallen, 146; cause and cure of, 162
Combrum purpureum pruning, 158
**Comfrey, 54
Composts, injudicious complicated, 136
Conifers at Mr. Mitchell's, 99**

- Conifers—soils and situations for, 124; on a clay soil, 126; hardness of, 164; select, 300
- Conservatory erecting a small, chambers for, 244; chambers and other plants, 55, 42
- Copings—boards for, 118; for walls, 154; tile, 203
- Cordon? What is it, 4, 43, 68; training, 71, 95, 198, 107, 153; straining wires of, 153
- Cork Poultry Show, 59
- Correa culture, 228
- Corynocarpus laevigatus, 23
- "Cottage Gardening," 239
- Cotton—hybridisation and culture, 123; culture, 117
- Cotyledon velutina, 71
- Covant Garden Market, 14, 32, 54, 78, 93, 117, 149, 156, 173, 190, 200, 227, 242, 261, 281, 299, 326, 329, 347, 365, 379, 394, 412, 427, 444, 460
- Cows—Kerry, 292; oilcake for, 216
- Cracking of fruit, preventing, 110
- Cree-Creeps, 252; sickle feathers broken, 300; described, 161
- Crickets—destroying, 78, 158, 203; in fernery, 330
- Crinum capense culture, 101
- Crocker, death of C. W., 206
- Crocuses—eaten by mice, 323; taking up, 412
- Crop, swollen, 136
- Cropping kitchen garden, 459
- Croquet ground, moss and plantain on, 158
- Cross-impregnation, effect on seed, 129
- Croton maximum, 296
- Crystal Palace, 347; Bird Show, 160; Flower Show, 388; Rose Show, 422, 454
- Cucumbers—and Melons, house for, 79; frames, painting, 102; moving plants, 115; ridge, 191; early, 172; forcing, 193; in flued pit, produce of, 200; bed making, 305; Dales, Cucumber, 243; without artificial heat, 244; heating a house small, 262; not setting, 330; culture, 393; in winter, 318; devoured by rats, 364; woodlice attacking, 365; litter, 365; growing in boxes, 365; leaves damping, 428; producing at Christmas, 460
- Capressus macrocarpa, 66, 140; and other Comifers, 6, 133
- Carriers, training Red, 428
- Carriers' refuse as a manure, 201
- Castard Apple, culture, 366
- Caulish's spring fowls, 237
- Cutting—and seedling management, 196; planting, 227; striking, 228; over a tube, 233
- Cycas Revoluta, soil, 15
- Cyclanthes—potting, 33; after flowering, 243; varieties of Persiam, 342; atitumum culture, 87; ripandum, culture, 365
- Cymbidium pendulum, var. atropurpurea, 423
- Cypresses, straggling, 33
- Cytisus Adam, 428
- DACTYLIS GLOMERATA VARIEGATA, 372
- Dahlia—select, 142; as a bedder, storing tubers, 295; imperialis, 273
- Daisies, culture, 240; double, 341
- Dalchampia Roehiana rosea culture, 1
- Damson trees, removing, 79
- Daphne indica rubra not flowering, 283
- Darlington Gardeners' Association, 261
- Days, hottest period of, 254
- Deciduous shrubs, list of, 86
- Dendroica—cumulata, 286; nobile, leaves brown, 395
- Dessert, plants for ornamenting, 360
- Dew, cause of on Vines, 244
- Dicrananthus phylla, 239
- Dickson, Mr. J. H., 52
- Dipladenia amara, 296
- Dosa grandiflora culture, 218
- Dorons—coloured, 58; weight and colour, 106; head and comb turning black, colour of eggs, 181; with inflated abdomen, 195; and Bacteria footers, 240; their merits, 301; Lady Dorking's trouble, 206; puny, 320; White, death among Grey, 400
- Doves—young ejected from the nest, 242; diving, 450
- Dracopis—also notes on, 253; propagating, 92
- Dragon Tree of Tenerife, 32
- Dragon's wood for, 100
- Drumming land Pt. theory, 78; an orchard and clay land, 99
- Dundee Poultry Show, 176
- Ducks—from Isle of Fern, 56; keepers, 88; Ashbury with Wild, 106; classes for, 13; wounded wild, 126; prizes for, 23; Black East Indian, 252; breeding, 268; eggs not hatch in, food for, 288; eggs infertile, making, 320; eggs fertile though no water, excessive in, 330; points of anatomy, 351; laying 111; culture, 450; age of Roule for breeding, 416
- Dumfries and Maxwelltown Ornithological Society's Show, 37, 61
- Eaton, Mr. J. M., 285
- Edgings—slate, 321; Sedums for, 452
- Eggs—for sitting, 64; marble nest, 106; selling, 146; packing, 146, 162, 265, 302, 332, 384, 413, 448, 462; distinguishing sex in, 180; double-yolked, keeping, 196; yolks, of pullets, for hatching, 259; selling boiled, 258, 350; with thickened skins, misshapen, 288; not hatching, 302, 306; pullet laying soft, 306; hens eating, 320; chilled, 351; protracted hatching, preserving, 354; excess of, 364; hens laying soft, 384; broken in the hen, 416; moistening up on hatching, 432
- Emigrants, warning to, 201, 482
- Emigration, 239, 277; of gardeners to America, 150
- Entomological Society's Meeting, 112, 238, 255, 301
- Euphrasia—striking cuttings, 101; treatment after flowering, 366
- Epidendrum ibacense, 423
- Epidendrum, 341
- Epworth Poultry Show, 383
- Eranthemum aspersum, 423
- Erythronium giganteum, 423
- Essex Poultry Show, 37, 61
- Eucharis amazonica to flower in August, 330
- Eucodopsis nageloides, 396
- Evergreens—list of, 80; in houses, 22; for pyramids, 100
- Exhibitions, horticultural in 1868, 557
- FASCINATION, 461
- Favorites, old, 293
- Fernery—growing plants in, 174; liquid manure for, 191; plants for wall of, 348
- Ferns—pithierous, 7; culture in stores, 79; propagating prolificous, 192; repotting, vaporising, 282; over-potted, compost for, propagating by spores, 283; mildew, 444
- "Ferns and Lycopods, Select," 423
- Pevelev, Golden, for bedding, 395
- Fife and Kinross Poultry Show, 59
- Fish—(also, 283; trees in a peachery, 200; cutting their fruit, 300)
- Fir, sowing Scotch, 191
- Fleas—in hen house, 88; driving away, 268
- Floors Castle, 113
- Flower-garden—plan, 544; planting, 54
- Flower gardens, attractions in small, 65
- Flower pots—paper envelopes, 229; where to be had? 255; forms of, 361
- "Flower Garden, Handy Book," 294
- Flowers of other days, 199, 258; lovely though common, 282; too much neglected, 278; drying, 316; spring, at Mr. W. Paul's, 358
- Foliaged (fine) stove plants, 101
- Forget-me-not for spring blooming, 412
- Fowls—birds, caution to, 194
- Fowls—soft food for, weighing with head downwards, 84; for a clay soil, 119; with ulcerated livers, not laying, 180; dying suddenly, 216; marking ulcerated intestines over fat, 222; chilled, pecking each other, 354; rice as food for, 369; dying without apparent cause, 375; removing mounting food required by, eating feathers, 432
- Frames—utilising, 15; lining, 157; propagating, 192
- France and Italy, notes from, 45
- Fraserley Poultry Show, 382
- "French Gardens, Gleanings from," 404
- Fruit—growing far north, 48, 149; trees underpotted, 192; in pots, thinning fruit of, 171; for north wall, 191; protecting pyramid, 193; thinning blossoms, 243; bush, 234, 291; on open walls, at the Mount, 297; removing protection from, 368; removing in winter, 280; lichens on, 433
- Fuchsias—wintered in a cellar, 147; growing for exhibition, 191; repotting, shoots diseased, 317
- Fumigating to destroy insects, 31, 353, 296
- Furnace for fire-heating, 100
- Furze for cover, 242

From observations taken near London during the last forty-one years, the average day temperature of the week is 41.9°; and its night temperature 29.4°. The greatest heat was 57°, on the 3rd, 1863; and the lowest cold 11° below zero, on the 4th, 1867. The greatest fall of rain was 0.86 inch.

DALECHAMPIA ROEZIIANA ROSEA.

THIS most beautiful and useful Mexican Dalechampia is certainly one of the most elegant plants that have appeared for many a year, and will be found a most welcome addition to our stock of those suitable for table decoration. It is also invaluable for the conservatory. The plant grows very freely, and is at all seasons covered with its pretty pink bracts, embracing in the centre the yellow flowers.

The flower and bracts are very much like those of the Bougainvillea, but are produced singly instead of in clusters. The flower is also much brighter in colour, and the habit of the plant is very graceful. No plant that I have seen can compare with this in respect both to leafage and richness of floral colouring. It has bright, glossy, green, sub-cordate leaves, about 8 inches long. The plant is very easily managed, and may be grown into a large specimen for conservatory decoration; when grown in 3 or 5-inch pots it is also most useful for decorating vases or flower baskets in the drawing-room.

One great advantage which this Dalechampia possesses over many other flowers is, that its flowers continue in great beauty for a long time; in a moderately dry temperature of 55° the flowers retain their freshness and beauty for three or four weeks. It will be a valuable addition to collections of stove and greenhouse plants, and will, doubtless, be made the most of for this purpose by the successful exhibitors of this class of plants; for graceful specimens may be easily grown without the aid of so many sticks and distortions as one usually sees at exhibitions. It will, therefore, present a very different appearance from many plants exhibited in stove and greenhouse collections. Its bright leaves, beautiful bracts, and yellow flowers will add much grace and beauty to future exhibitions.

Where the object is to form the plant into a large specimen, either for exhibition or other purposes, it should be placed in a rather high and moist temperature of 70° or 80°. Every flower bud must be picked out as soon as it appears on the stem.

The soil most suitable is a mixture of rich, fibry, yellow loam, peat, leaf soil, and cocoa-nut refuse in equal portions, with a little small charcoal, and just enough silver sand mixed with it to keep it sufficiently porous. The drainage must also be perfect.

As soon as the roots have reached the sides of the pot the plant may be shifted into one a size larger. It must at no time be allowed to suffer from want of water, and if supplied with weak guano water once or twice every week after the pots are full of roots, rapid growth will be encouraged, the brilliancy and size of the flower and bracts will be increased, and the foliage will acquire a deeper colour and more glossy appearance.

No insect appears to trouble the plant much, excepting scale and white mealy bug; but these, however, may be kept under by constant vigilance and attention on the part of the person in charge of the stove or other house in which the plant may be cultivated.

The best way to propagate this beautiful plant is by cuttings. Having taken a shoot, it should be cut up in pieces about half an inch long. This will give two eyes: one at the base of the cutting, the other at the top. The leaf stalk at the former should be trimmed off close to the stem of the cutting; but that near the top eye should be left entire, with about three-parts of the blade of the leaf attached to it. The cuttings are best pricked into small thumb-pots. The soil most suitable for them is a mixture similar to that recommended for growing the plants in. It will, however, require to be rubbed through a fine sieve, and a larger proportion of sand will be necessary. Great care must also be exercised to put plenty of drainage in every pot. If the pots are 3 inches high, at least 1 inch of drainage should be placed at the bottom, and this should be broken in pieces of a regular size: first put in about half an inch of larger pieces, then a half-inch layer of smaller pieces. This will cause the water to find its way through the soil in the pot regularly, rendering the soil equally moist throughout.

It often happens when the drainage is placed in a cutting pot in a careless way—large pieces and fine siftings all in one indiscriminate mass—that on turning the soil out to see what is the cause of one half of the cuttings in the pot striking properly and the other half being dried up, one half of the soil is found to be as dry as dust, whilst the other part will be quite wet. The cause of this is not placing the drainage properly in the pot. This is a point I am very particular about, whether the pots are for cuttings or grown-up plants.

The soil should be pressed into the cutting pots so as to be moderately firm; then a quarter of an inch of clean silver sand should be put on the top, and when this is pressed down there should be a space of not less than half an inch between the surface of the sand and the rim of the pot. This is another point that should never be lost sight of in making-up cutting pots or pans for any kind of plant: for if the pot is filled up level with the rim, and the sand is pressed down very closely and firmly, in a short time a solid crust will be formed by the sand, and when it is found necessary to water the cuttings, the water runs off the sand instead of passing through it; but when there is a space left between the rim of the pot and the sand, that space will generally hold sufficient water to wet the whole of the soil in the pot; if not, more can be added as soon as that previously applied has soaked away. Want of attention to minor details such as those I have here mentioned is often the cause of many being unsuccessful in whatever they may undertake, whether it be the propagation and management of plants or anything in connection with business of other kinds.

Having properly prepared the cutting pots, the cuttings may be inserted in them, one in the centre of each pot. They should be put in to a sufficient depth to be made firm in the soil. If the hole made by the dibber is an inch deep it will be sufficient for all purposes. The soil should be pressed close to the cutting.

After the cuttings have all been put in they may be watered, and allowed to stand on the potting bench, or on

a curb in the stove, till the water has soaked through the soil, so that the whole body of soil and the drainage may be in a good condition before plunging the cutting pots in the propagating frame. If the plunging material is in a proper state as regards moisture, no water need be given before the cuttings are struck. The soil is thus prevented from becoming sour, and, as a consequence, the cuttings root more quickly, and grow much more freely afterwards. A bottom heat of 70° will be found sufficient.

As soon as the cuttings are struck, and their roots have reached the sides of the pots, they may be shifted into 5-inch pots, which should be again plunged in a similar temperature until the roots have reached the sides of the pots. By this time each plant will be from 5 to 7 inches high, and its stem thickly studded with flower buds. The plants should then be taken out of the plunging material and placed in a moist stove as near the glass as possible, and after remaining in that position a week or two may be gradually inured to the temperature of a cooler house. From there they may be taken into the conservatory, or wherever they may be wanted.

Plants grown on in this way are fine objects for decorative purposes; and one of the most useful features in this most beautiful plant is that it may be had in bloom from one year's end to the other. No nobleman's or gentleman's establishment, where a constant display of gay-blooming plants is required, should be without a hundred or two of these beautiful plants in various stages of growth. I venture to predict a brilliant future for this lovely Mexican. At present its price places it beyond the reach of many, but I consider if ever any plant was cheap at two guineas this is. I have no doubt but in the course of two years it will be sold in Covent Garden Market by the hundred or thousand at 1s. each. What we want now is the same plant with scarlet, red, purple, and white bracts.—J. WILLS.

CROSSING THE EARLY HARDY VARIETIES OF GRAPES.

I HAVE recently had a letter from a gentleman in Lincoln to the following purport:—"I have seen lately in THE JOURNAL OF HORTICULTURE a paper from you relative to the crossing of many kinds of fruits, but I do not see Grapes mentioned amongst the number. I write to ask you if you ever do anything in that way, because many thousands about London, and, I may say, over the midland counties and south of England, are growing Vines in cool houses, ground vineries, and out of doors. These classes, at least most of them, being in business, or much engaged all day, do not keep a gardener, and, therefore, cannot attend to a furnace to heat their houses, but love to cultivate the Vine—I say these classes feel the want of a greater variety of early hardy Vines, with large berries and good flavour. Another acquisition for the above classes would be the raising of an early Grape without stones, and of good size and flavour. Perhaps the crossing of the Black Monukka or Sultana with some of the best early kinds might bring about this result. You may ask me, Why cross a stoneless Grape at all? but you are aware that all stone fruit stand still while the stone is forming—the Grape amongst the rest. Now, I want to save the three weeks, the average time the Grape is standing still. By producing an early Grape without seed, I am convinced you would be doing a great good to a very large class, who would cause a very large and, I might say, a very profitable demand for it."

Next year is likely to witness the "battle of the new seedling Grapes," and by the flaming descriptions given of them, it will be all up with our Muscats, Buckland Sweetwaters, Trebbiano, Alicante, and Lady Downe's as soon as the new sorts come into bearing. The new sorts, however, being described as principally of the late kinds, and requiring fire heat to bring them to perfection, I think that something new in the way of hardy early Grapes is wanted for amateur growers with unheated houses.

I am at the present time forming a collection of the very earliest hardy Grapes to plant in places in the border of an unheated glass-covered wall, and have the following planted, or about to be planted out—namely, Early White Malvasia, the very earliest of all white Grapes, and of excellent flavour; Madeline Royale (Rivers), Early Smyrna Frontignan (Rivers), Muscat St. Laurent, very early, with Muscat flavour; Royal Muscadine, Foster's White Seedling, Chasselas de Falloux, Early Saumur Frontignan, and the true Esperione. I should

be glad if any grower could add some good early sort to the above list, and more especially an early variety with only one stone in the berries. The noblest black Grape we have, the Damascus, has only one stone in the perfect berries, but it is a late Grape, and rather a bad setter. The Sultana I do not grow, nor any other seedless Grape except the Black Monukka. This is a most interesting variety, producing very large bunches, with small, oval, heart-shaped, seedless berries, and the flavour is very rich and vinous. When left to hang long on the Vine it is delicious to eat, or put into jellies. As the flesh is so crackling, the berries can be eaten skin and all. I intend trying to cross this variety with some of the best of the early sorts, and as the seedlings will be fruited in pots, three or four years will suffice to prove a large collection.

Perhaps some other growers may try their hands at raising some new varieties of hardy early Grapes, for there is a great want of showy kinds with large berries both for early forcing and for growing in unheated houses. The list of late Grapes, or varieties that require fire heat to come to perfection, is now extensive, and it will require very good seedlings indeed to equal our Muscats, Frankenthal, Alicante, and Black Damascus.—WILLIAM TILLERY.

PROPAGATING PELARGONIUMS.

I THANK Mr. Stewart for his reply to my communication, and hasten to inform him the reason for coming to the conclusion at which I arrived.

My firm opinion is (and I believe a great many propagators of softwooded plants will bear me out), that cuttings of softwooded plants require a change of air every twenty-four hours at least, to carry off damp and other impurities, which accumulate in either a bell-glass or close-kept frame—damp which is so destructive to Pelargoniums and other softwooded cuttings.

Mr. Stewart in his communication, page 419, says that his cutting beds are well watered before the cuttings are planted, and that a thorough soaking is given after the cuttings are inserted. I prefer letting the soil have no water until after the cuttings are planted. Mr. Stewart also says that he shades in very bright weather, and gives "no air" until the cuttings begin to grow. It is here where "the mist" came over my eyes, and I shall be glad if Mr. Stewart will make me see more clearly by stating exactly how many cuttings per thousand he actually loses by his plan.

We do not begin so soon as "R. E." page 277, whose plan is good, only it involves more labour; but we begin during the first week in August, and finish about the beginning of September, or very often the middle if other work is pressing, and we do not cut away at the plants indiscriminately, but take a cutting here and there from the sides as well as from the middle of the beds, when a shoot can be cut off without being missed. By so doing the beds are not robbed of their beauty, but, on the contrary, they are simply regulated and put into shape.

As I before remarked, Mr. Stewart's plan may answer under his own management, but I think a Pelargonium struck in August will keep through the winter better than one struck in September, unless the propagator can run to the coal heap just as he likes. However, if Mr. Stewart will convince me that he does not lose more cuttings on the close system than those who place them in the open air, I will frankly admit that I have learnt from him a good lesson. Mr. Stewart was asked to give his method, and he did so in a very kind manner, and I am sure he will pardon me for commenting on his communication.

Does Mr. Stewart grow much of the Pelargonium Gold Pheasant? It is a much better grower than Golden Chain, and a variety which I think will supersede the latter. If Mr. Stewart does not grow it for borders, I should be happy to send him a bundle of cuttings.—JOHN PERKINS, *Thonham*.

HAVE PATIENCE WITH PEAR TREES.

I WANT to record a word in favour of a Pear tree—for the sort in particular, and to encourage amateurs in a patient waiting for good results.

I planted a small tree of Beurré Clairgeau amongst many others either eight or nine years ago. It grew vigorously, and after four years bore a good crop of fruit, which it has continued to do since, but mealy and poor in flavour. This year

however, it has borne the crop as follows:—276 Pears safely gathered on the 20th of September; weight of first size 7½ lbs. to the dozen; second size 5 lbs. to the dozen. Some were fit for table about the 20th of October, and some were in the highest condition on the 12th and 14th of this month (December); quality very good, juicy, firm, very sound, and of very good flavour, superior to most bought Pears of greater renown.

The tree stands about 11 feet high, occupies little space, is a pyramid clothed from the ground, and as handsome as can well be.—CHARLES ELLIS, *Upper East Sheen*.

VINE-GROWING AND NATURAL TEMPERATURES.

I SEND you an abstract of the climate of Jerusalem, as being one that cannot fail to interest your readers. This abstract I have taken from the Journal of the Scottish Meteorological Society for the quarter ending June 30th, 1867. It is accompanied by a most valuable comment; but I do not propose quoting from it, contenting myself with asking your readers to turn to "H. S.'s" two letters, at pages 113 and 212 of the last volume. I most sincerely thank him for having drawn my attention to the practical lessons to be gained from the study of this particular climate.

I will now turn to the other portion of my title, Vine-growing. I have been for more than a year intending to send you my views and practice; first, I had not time, and then I waited to see what "H. S." would say; but he states, in answer to "G. S." at page 381, that he has "no mode of Vine culture," so I will now send it in the form of a letter. I do this because I am not prepared to write a treatise, nor even claim as "my treatment" the plan I thus commend: it is simply the plan I follow. Let those whose eyes are not closed, and whose ears are not stopped, think of these things as well as I do, and judge if it will suit them. I cannot and do not say it will enable either me or any one else to take the prizes given for Grapes at the London shows over the heads of gardeners. Only the cost determe from making the attempt at present. When it is worth my while I will try; till then I leave this art out of the question, and apply myself to the cheap production of Grapes.

Shape of Vinery.—If there are no reasons other than cost to bias the decision, the span-roof is the best; but if you have a wall, make the house a semi-lean-to with a tall front.

Ventilation.—By all means adopt the double ridge board with the rising eap. I should also advise a front ventilator to be used to put the Vines in the house to rest, or retard them when required.

Glass not wider than 12 inches; 15-oz., except in doors. Laps to be puttied.

Borders all inside, to stand on single brick arches made half round, no mortar being put between the brick ends; to run across the house. The front foundation to be put in after the back, sides, and arches. No excavations required, but remove the soil, and if the subsoil is clay, slope it to the middle, and there have a good drain. The door can be reached by an incline either to the middle or end. The bed should be made by filling the arches level with good drainage, this being covered with soda wrong way up, and then with the soil, with a due quantity of helps to drainage, and some bones.

Mode of Planting.—If a span-roof, in two or four rows, as of 10 or 20 feet in width; if a semi-lean-to of not more than 12 feet wide, in rows across the house 6 feet apart. With wider houses more room is required to let the light down the rows to the back wall. Vines should be put in at every 4 feet, and planted after they have started fairly; to have four starts, each a foot apart, and when planted a good peg should be put between each start or shoot. This is nothing less than layering each young rod. Grow them as long as you can without any stopping, laterals included—that is, keep every leaf you have room for. When they have grown as long as they can, cut every other shoot halfway down. When these are well going again, treat the remaining ones the same, and grow all up again, thinning the first-cut-down to make room for the last if needed. When you want the Vines to go to rest, let out the fires and open all the ventilators, leaving them open all night. This is sufficient anywhere in England, except during June, July, and August. If you want to start the Vines in these months, do not require a rest from them; prune them in, cutting all leaves off, and with young Vines shorten them to the first cutting-down place. As the Vines become strong you can reduce them to two rods each if you like, or cut them down

in alternate years, grow a young cane on the border, or shorten them in; but grow a young cane by all means even if you cut it off again, to keep the roots going during the stoning and ripening time; from the beginning of the crop to the resting time always have young growth.

Watering.—Do it every week without fail, and feed your Vines with what you thus wash in, changing the manure weekly, and giving very little each time.

Syringing.—With young Vines syringe night and morning, and oftener in warm, dry weather, when plenty of air is given, and the leaves are fairly grown—always with warm water. Nothing is better to make the Vines grow than the syringe, nor is there anything that helps them so much to swell their canes when they are going to rest.

Temperatures.—Take the climate of Jerusalem, and then you will grow Grapes ten months in the year, and need not fear cropping the year after planting.

I will not now occupy your pages further, though to enter fully into each of these heads page upon page could be written, neither will I give examples lest I may seem to boast. I have nothing to gain by giving my name to the public. I practised gardening for pleasure, and now continue it for profit.

Recapitulation.—In taking out a patent you are required at the end shortly to state what you specially claim as new. In this case I claim nothing as new, so I will instead fill up the place with what I consider the most important points. These are—length of season of growth, and particularly after the crop is gathered; the use of the syringe more or less all through the season, whether there is a crop or not, thus insuring continual growth; a dry, well-drained border, enabling you, without the least chance of making it sad, or water-logged, to wash food down to the roots each week, as suited to the wants of the Vine at that particular period of its growth; system of putting as many Vines as possible in a house, and mode of obtaining as many canes from one Vine as possible, and thus being able to shorten or prune one cane without giving the roots any check—a mode of quick returns, well suited to amateurs' wants and patience.

"H. S." says he has obtained 1986 bunches from 1700 square feet of glass. If planted in this way I am of opinion 8 ozs. per square foot can be obtained year after year.—G. H.

ABSTRACT OF METEOROLOGICAL OBSERVATIONS MADE AT JERUSALEM FROM 1ST OF MARCH, 1865, TO 28TH OF FEBRUARY, 1867. Height above the sea, 2500 feet. Monthly means and extremes on a mean of these three years.

	Highest in Month.	Lowest in Month.	Monthly range.	Mean of all the highest.	Mean of all the lowest.	Mean daily range.	Mean temperature.	Number of days.	RAIN. Amount in inches.

WORKING ROSES ON THE MANETTI STOCK.

How true is Mr. Radclyffe's observation, that we must wait two years before we can see any bloom worth notice from a removed Briar Rose bought in from a nursery; and, on the contrary, a Manetti Rose removed in winter or autumn generally blooms, and does better after removal. Thousands of rosarians, myself included, have fully experienced all this. Briar Roses do well with me, because I have a rich, deep loamy soil, but Manetti Roses do better.

I have budded Manettis in the following manner, and find they take more freely:—Suppose a Manetti stock to be firmly rooted, having had a year's growth, cut it down close to the soil in the spring. Three or four strong shoots are sent up. I bud all of the shoots about 3 inches from the ground, say in June or July, let them remain dormant, and cut them down in the

usual way in the following spring. I let them all grow until the shoots are a foot high—about June—I then soil them up like a Potato ridge. In November I take the whole root up, and divide the plant. I have thus three or four Manetti Roses from one stool. By this means one can propagate many Roses in a small space. I have never yet heard of any other person practising this system. I find it to answer well.—HENRY TAYLOR, *Fencote, Bedale*.

THE GLADIOLUS AND ITS CULTURE.

THE Gladiolus has long been a favourite flower with me, and when I first grew it, *G. insignis*, one of the hardest of the tribe, was treated here as an exotic.

Had the melancholy but valuable communication of "D.", of Deal appeared in November, 1866, instead of 1867, I should have had a cordial fellow feeling with him, for in that year my Gladioli were wretched. This year, with the exception of *Brenchleyensis*, not one of which has flowered, they have, with the same treatment, in the same place, and in soil of exactly the same nature, done remarkably well.

"D.'s" experience in 1867 is similar to mine of 1866. In that cold year many of the Gladioli never bloomed at all with me; and others, especially John Waterer, Madame Pereire, and Madame Leseble, after blooming well, immediately began to show signs of premature decay in the foliage, and when the roots were taken up, they were black, shrivelled, and dead. The bulbs of Clemence and Reine Victoria had so many black spots that I almost gave them up, but to afford them a chance they were planted this year, and produced fine spikes of flowers, and made good roots, without a black spot upon them. Another grower near, who in 1866 was very successful, has this year been equally unfortunate. Can any of your more scientific readers suggest the reason, or better still, a remedy?

Possibly any way of treating Gladioli may interest some of your readers. I do not like them in beds. The Tulip, the Ranunculus, and many other lovely flowers, are eminently fitted for beds. I do not think the Gladiolus is. The borders surrounding my little flower garden are raised, and broken-up with pieces of limestone, with spaces of varying size between each stone. These spaces are now filled with double Tulips and Hyacinths in pots. As soon as their bloom is over, the bulbs are taken up, put away to ripen, and their places refilled with fresh compost, a little dung being placed about 10 or 12 inches below. The Gladioli, which have been reared as will be afterwards described, are put out of their pots into the vacant spaces. I use very much the same compost as for the Lilium—rotten turf or fresh soil, and as I obtain it from strong land, I add one-third of a mixture of sand, charcoal, and cocoa-nut fibre, sometimes a little peat.

The best and most valuable kinds I always plant in 6-inch pots, one in each, about the end of March. They are then placed in a frame with gentle heat, alongside half-hardy annuals, and plenty of air given. By the time the blooming of the Tulips is over, or soon afterwards, the Gladioli are about 6 inches high and ready to plant-out. The bulb in the ground is covered with 4 inches of soil, and as the leaves grow they are moulded-up with an inch or two of sand, or sandy loam. In dry weather plenty of water is given, and, perhaps, once a-week liquid manure. In one case I found a top-dressing of soot useful. I had a large, flat, indented bulb of *Shakspeare*. When its leaves appeared they were of an unhealthy whitish green colour. I feared, and I was not alone in my fear, that I should lose it. I placed at different times a little soot round the plant, and soon had the gratification of seeing it recover a healthy hue. It bloomed and produced two good bulbs.

I wish I could ascertain the best time for planting in the open ground. An enthusiastic grower, whose method I give afterwards, plants in February, and his flowers do well. M. Souchet recommends later planting. I had last November some very small bulbs which I did not care to store; they were planted in the border, a little protection given, and covered with a hand-glass. They all stood the winter, and some of them bloomed well and made fair bulbs.

I have found the flowers much improved by shading. I use a cylindrical case, 9 inches in diameter, and 24 inches long, of the ordinary 24-inch galvanised wire; this is fastened firmly to a stake, and covered with thin muslin. The flower is safe from wind, rain, and sun, and its colours are both more vivid and more perfect.

My friend referred to before pursues quite a different plan.

He grows his Gladiolus in a bed. The soil of his garden is very strong; he takes it out 3 feet deep, then throws in turf 4 inches thick, next a layer of cow dung that has been well turned over in winter, then rotten turf and loamy or sandy soil. On this he plants the bulbs in cocoa-nut fibre, and covers with 4 or 5 inches of loam. I do not agree with this. I cannot see of what use the manure 18 inches below the bulbs can be; the rootlets never seem to penetrate more than 6 inches. I must, however, admit he has splendid flowers.

Added is a list of the varieties we consider best here, and that bloom well with us. Those marked with an asterisk (*) are best.

White.—*Shakspeare, *Princess Mary of Cambridge, clear flower, but petals rather pointed; *Reine Victoria, Marie Dumortier, *Madame Leseble, and Madame Pereire.

Lilac.—*Impératrice Eugénie, *Belle Gabrielle, *Madame Furtado, and *Madame Vilmorin.

Rose.—Dr. Lindley, Madame Basseville, Princess Clothilde, Charles Dickens, and *Penelope, flesh.

Cerise.—Florian, Le Poussin, Lenué, *Duc de Malakoff, *Madame De Sévigné, and *John Waterer.

Red.—Achille, *Meyerbeer, Napoleon III., *Prince of Wales, *James Veitch, *Maréchal Valliant (very fine), *Sir William Hocker, and *Fulton.

This is not written under the opinion that the treatment here mentioned is the best, but in the hope of inducing those who have been much engaged in the culture of the Gladiolus to detail their experience, and to enumerate the varieties they deem the most choice, and the best worth growing by those who, having only small gardens, wish for the most select kinds.—E., *Darlington*.

WHAT IS A CORDON?

Is the course of the discussion which has recently been going on about French and English Gardening, the term *cordon* has been so frequently used, and in a sense so indefinite and vague, that a few words on the subject may not at present be unreasonable. The English equivalent of *cordon* is a line, and hence the French use the term in many different ways. It is employed to signify a line, cord, or rope. It signifies also the rim of a piece of money, the ribbon round a hat, and the ribbon of the Legion of Honour is also called a *cordon*.

In the early part of last century, when geometric figures were then, as they are now, so much in vogue in gardens, the strips of grass between the beds were called *cordons*; but this is the only sense in which it has been used in French gardening till of late years, when the term was applied to the branches of the Vine pruned on the Thômy or spur system, which were also called *cordons*. It is about five and twenty years ago that M. Du Rœuil introduced the word to express certain modes of training, which we have called "the spur system," in contradistinction to "the laying-in system" of pruning, because of its being in a continuous line, or like a rope. He defines *cordons* as "the primary ramifications of the stem, and which are generally simple," and in his work he speaks of many forms of *cordons*, using the word generically, and not specifically; as, for instance, the "*cordon horizontal simple*," which is exactly the form of the letter T; the *cordon oblique*, which is a simple branch trained obliquely at an angle of 45° against a wall or espalier instead of horizontally; and the *cordon vertical*, which is also a simple branch trained perpendicularly.

During the discussion above alluded to, one of the disputants used the term *cordon* in a very limited sense, conveying the idea that it referred only to the *cordon simple* manner in which Apples and Pears are trained to form edgings to garden walks, and to clothe the bases of walls; and a considerable amount of misapprehension has arisen as to what a *cordon* is, from this specific use of the term. *Cordon training* in its general sense means simply a tree with all its branches, no matter how many, coming directly from the stem, and all close-pruned so as to preserve them perfectly simple. Thus, Du Rœuil calls our horizontal mode of training the Pear in successive tiers of *cordons*, "*palmette cordon*." Mr. Bichaut, in his admirable little work on *cordon training*, defines the system as "a certain number of leading branches carried out, and on them spurs are developed, so that the branches look somewhat like twisted cables or chains."

Cordon, therefore, means not any particular form of trained tree, but rather a particular mode of pruning fruit trees, by which any branch or number of branches acquire the form of a

cordon or line. It is, in fact, what in English gardening we call a branch pruned on the spur system, which every gardener knows possesses no novelty. The only novelty connected with cordon pruning are the fanciful forms in which the French have of late years delighted to train their trees, but which do not in any way contribute either to their health, longevity, or fertility, more than our own practice which has been followed so long.

BEDDING PLANTS THAT WINTER WELL IN A COLD PIT.

ALTHOUGH from time to time vigorous attacks are made on the bedding system by those who wish for a return of the old-fashioned mixed border, yet it is apparent to every one that the system is still gaining ground. Whether a change is near or distant, there can be no question that the present demand for bedding plants is a heavy tax on the means of many who have to produce them, and the utmost ingenuity has to be exercised to furnish the necessary number every season; as a consequence, due attention is always paid to any plan which in reality lessens the labour or simplifies the means by which the end in view is attained. The great object aimed at of late years has been the wintering of a large number of plants with the least possible assistance from glass structures provided with artificial heat, and whenever glass can be dispensed with so much the better. With some plants this cannot be done without increasing the labour to an extent more than equivalent to the cost of employing glass, and of this class are the bedding *Pelargoniums*, which occupy the post of honour among bedding plants, but which are rarely met with in a fitting condition to plant out in May without having in some degree had the benefit of a heated glass structure during the preceding six months. Of these, however, enough has been said of late; and I will, therefore, confine myself to a class of plants scarcely less important, but which may be kept through the winter with much less trouble and expense. My object is to enable the inexperienced to make the most of the means at their command, and so to give to the more delicate plants the most suitable positions, while to the others may be assigned such quarters as can be afforded them.

In some communications which appeared in this Journal early in the autumn, the ease with which the *Calceolaria* could be propagated, and kept over the winter almost without the aid of glass, was pointed out, and without either pots or artificial heat. I wish that, in addition to the information then given, some easy means could have been devised for ensuring the success of this plant throughout the summer; but I fear we must employ such varieties only as possess greater constitutional strength than most of those now grown, and in so doing no doubt we must be content with either species or varieties not so ornamental as those we have hitherto employed. Amongst the plants, however, to which a cold frame affords sufficient winter protection, the bedding *Calceolaria* stands pre-eminent, and its capability of withstanding the influence of long-continued moisture is of the highest order; even a little frost does not effect its destruction when the change from that condition to one of a contrary kind is gradual. A fortnight or three-weeks seclusion from both light and air is also harmless to this plant.

Centaurea gymnocarpa.—This, though not hardy, is, like the *Calceolaria*, not killed by a slight frost. It will also endure the damp atmosphere and confinement of cold-frame treatment without suffering much. It is well to insert the cuttings by the 1st of October, which is a month earlier than *Calceolarias* are often put in; but they will do very well even put in at the same time as these. I cannot say that I have been so successful with *C. candidissima*; but its failure did not arise from the plant not standing cold, but from its not doing well with us during the summer. The plants became sickly, and decay set in at the ends of the leaves; the cuttings, therefore, were not a fair sample, otherwise I expect this plant is much more hardy than is generally supposed.

Gazania splendens is almost hardy, and plants in a sheltered position will sometimes live through a mild winter out of doors; but if cuttings are inserted in the cold frame early in October, they make, in April or May, as good plants as can be desired, and we have occasionally obtained cuttings in April from plants so treated, which formed neat little subjects by the usual bedding-out time. No plant that I am acquainted with does better than this, and looks better when planted out.

Nierembergia gracilis.—This and its varieties, though hardier, perhaps, than even the *Gazania*, do not strike so freely from cuttings put in about October; indeed, the plant is often a collection of flower stems. I have sometimes taken plants up and divided them, and planted rooted offsets in the cold frame or pit, but the success was never so great as with the *Gazania*. In sheltered situations in the open air, the *Nierembergia* often withstands the winter, and furnishes cuttings in February, which strike fast enough in heat. In the cold pit its defects would seem to be the absence of suitable cuttings, rather than its not standing cold, for we have many instances of its surviving the winter.

Cineraria maritima.—When well grown nothing can exceed the beauty of this. It certainly excels *Centaurea candidissima* in gracefulness of form, although the latter may surpass it in whiteness, and in the property of not running to flower; or rather its commencing to do so does not affect its appearance so much as in the case of the *Cineraria*; but the facility with which the latter is propagated, and the greater certainty of its succeeding when planted-out, give it an importance not always accorded to it. Cuttings put in early in October, make very good plants in May, with no more attention than is given to the *Calceolaria*.

Lobelia speciosa.—Although old plants taken up and pulled to pieces, with a little root attached to each, and so planted in the cold pit, will, in some cases, do very well, they do not always succeed. It is, therefore, better to raise seedlings in the ordinary way, as this plant seems less hardy than those previously named. Occasionally, however, batches of plants may be wintered in a cold pit, and if some very late seedlings were obtained, and planted before flowering, they would be certain to succeed.

Veronica Andersoni variegata.—This has not hitherto been adopted to the extent which it deserves to be, as it is certainly one of the prettiest of white-edged plants. It is readily propagated by cuttings put in at the same time as the above, and it is rarely that one fails to become a plant.

Eunymus japonicus aureo-variegatus.—This plant has with me failed to thrive so satisfactorily as was expected, the growth in summer being very limited. It is easily propagated, and stands well in the cold pit in company with the other plants named. Plants out of doors also withstood last winter, but they were under the snow. It is much to be regretted that its tendency to run into the green state is so general.

Pentstemon.—These being thought hardy, are only mentioned to state that autumn-put-in cuttings, treated the same as the others, form good plants by spring.

Erythraeus.—Like the *Pentstemon*, this is known to be hardy, but, nevertheless, it requires to be propagated every year. Slips or cuttings put in during October, furnish well-formed plants by April, from which other cuttings may be taken, which root freely under hand-glasses out of doors, or in any place where not too much exposed to the full sun.

Cupheas are certainly not so hardy, but will do in a cold frame or pit. They will not endure so much damp as the *Calceolaria*, and long confinement is apt to thin their numbers very much, but they sometimes pass through the winter with but little loss, and make good plants early in May.

Verbenas.—Not being always successful with them, I cannot recommend them for cold-pit culture in winter. Probably if the cuttings were put in earlier they might do better, but this is not always convenient, as the pit may have something else in it at the time. *Verbena pulchella* is the most likely to prove satisfactory, or *Verbena venosa*; the latter, however, not by any means so generally good as might be wished for. Scarlet and other-coloured *Verbenas* in general use are seldom taken up in time to plant here, and as none of them will endure the long confinement necessary when cold weather is prolonged, it is better to have a stock of plants elsewhere to propagate from when spring commences.

Petunias.—These will endure cold but not damp, so that I have never done any good with them here, and, in fact, have not tried them often.

Cerastium tomentosum.—Plenty of this should be secured in cold pits; not but that it will endure cold and frost well enough, but long-continued wet weather and a cold wet situation are sometimes fatal to it. This plant was not by any means plentiful last spring.

Besides the above, there may be many other subjects to which a well-constructed cold pit affords all the protection necessary in ordinary winters. My worthy friend, Mr. R. Fish, gives the preference to a turf pit over a brick one, and for

summer purposes perhaps it may be better; but I have often thought it harboured slugs and other insect enemies more than blackwork does; besides, the latter is neater. Generally speaking, an ordinary light is a sufficient protection, excepting in very sharp weather when there is no snow, then some additional covering may be put on; but snow is a very good protection, and it is seldom advisable to disturb it when once the pit is covered-up with this natural mantle. For some days after it has disappeared, and mild weather has set in, it is not advisable to let in the external air in too great quantities. This, however, will be best understood by the condition of the plants, or rather cuttings, inside. If they appear fresh and only covered with moisture they will sustain no injury, and may be gradually inured to the air; but if some are decaying, and mildew is attacking them seriously, let such be removed and drier air admitted, which, in fact, will be the case when the work of removal is being done.

It must be remembered that the object of relieving the heated structures of plants that will winter elsewhere is one of the reasons for recommending the plants named to be consigned to the cold pit, which, indeed, is better for many of them; and as it is supposed that all are put into the ground at once, and not into pots or boxes, only the hardiest plants are enumerated. The little trouble they give must be apparent. I need hardly remark that *Verbenas*, *Petunias*, and *Cupheas* would be better kept elsewhere, as well as *Lobelias* raised from seed in the ordinary way. All these, and even bedding *Pelargoniums*, will do very well in the cold pit, excepting during the dark dull days, say for two months or more, beginning with the 1st of December. A well-filled cold pit affords a greater number of plants in spring than any other structure of a like size, and that, too, with but little trouble or expense.—J. ROBERTSON.

EAST LOTHIAN PURPLE AND WHITE STOCKS.

I WAS much pleased to observe that Mr. D. Thomson had, in a recent number of this Journal, directed attention to the excellence for bedding and other purposes of what he calls the East Lothian Purple and White Stocks. He most justly ascribes the production of these to Mr. Campbell, gardener, Traprain, a name well known in East Lothian in connection with the culture of Stocks. Although it is several years since Mr. Campbell, after much care and labour, succeeded in producing these, still, as yet, his productions are comparatively little known out of the district in which he resides. He was generous enough, however, to distribute his small stock of seed amongst his gardening friends in East Lothian, and time enough has elapsed to prove and establish their constancy.

Several years' residence in the locality enabled me to see, at the raiser's and other places, and to judge of the merits of these Stocks, and I can fully corroborate all that has been written by Mr. Thomson in their favour. Indeed, for the decoration of the flower garden in autumn, whether grown in beds or borders, they are invaluable. They continue to bloom long after most of the bedding plants now used have been removed; thus having a twofold use—namely, affording a supply of cut flowers at a season when the usual resources are gone, and extending the season of bloom.

Having last autumn, through the kindness of the raiser, been supplied with a few seeds of these Stocks, and the seedlings being duly cared for, two rows were planted under the shelter of the mansion. These are still (December 20th), wonderfully gay and attractive. Others planted in an exposed situation have only lately ceased to be so. The purity and brightness of the flowers, the certainty of 70 or 80 per cent. being double, and their compact bushy habit, are other high recommendations to these Stocks.

Apart altogether from the Scarlet Stock, so much grown in East Lothian, and mentioned by Mr. Thomson, I may state that Mr. Campbell has also a scarlet of his own producing. I have had the two varieties growing side by side last season. The flowers of the latter are, I think, brighter, and the habit is certainly more dwarf and compact. The per-centage of double flowers is about the same in the scarlets as in the Purple and White.

In pots for in-door decoration these Stocks also become highly serviceable. The plan which I have adopted when I want them for this purpose is to deprive of their flower spikes a few of those planted-out, and which have proved to be double; to lift them carefully, and to pot in October; to water and place them in a shady situation; and on the approach of

severe weather, to move them under protection. Such will flower at almost any season, but are better of being kept growing, and of their flower spikes being kept off till May or June, and shortly afterwards they will be a mass of bloom, fit for almost any purpose, making a display such as few plants could excel or even approach.—J. A., *Wallhouse Gardens*.

CUPRESSUS MACROCARPA AND OTHER CONIFERS.

IN Mr. Kent's excellent observations on the *Cupressus macrocarpa* I wish to notice one point in which my experience differs from his, and to give a word of encouragement to those who live on heavy clay soils, as regards the growing of this very beautiful Conifer.

I may say without fear of contradiction from any one acquainted with the spot where I live, that it is on one of the stiffest clays in England. In 1860, I made a mound in an open and airy situation with the clay dug out in making a pond, some of it only being the top spit with a barrowload or two of rather finer soil for the roots to settle in. In this I planted a *Cupressus macrocarpa* from a neighbouring nurseryman, which was then, I should imagine, about 6 feet high. Two years ago it was nearly blown down, but it is now 26 feet high, and 13 feet through in the widest part, and it would have been much wider than this had I not cut off the tops of many of the largest branches in the manner described by Mr. Kent recently, as it was growing lop-sided. Notwithstanding the severity of last winter, the thermometer here having been down to zero, it only lost one branch, and is even at its present age a very beautiful tree and growing vigorously, although within a hundred yards or so of it *Pinus insignis* was killed.

Not far from this tree, but in a rather more sheltered situation, I have three specimens of *Cupressus Lambertiana* (which is so similar in its character to *macrocarpa*, that as far as fitness of situation is concerned, it may be considered identical),* which I raised from seed, I think, in 1857. They are all growing in still stiffer clay than *C. macrocarpa*, as one of them is in the blue clay which was taken from the bottom of the new-made pond, and the other two are in the original soil which has never been moved. They are all growing most vigorously, none of them being materially injured except one, which lost 3 or 4 feet of its leader and side branches last winter, but as I have not yet cut it, I measured it yesterday, and found it to be rather over 10 feet, and nearly as broad as it is high. Of the other two both of them are nearly as large as this; one is not injured at all, and the other has only lost one or two small branches, but in other respects is perfectly healthy and of a beautiful colour. In fact, I have never seen, hardly I think in the *Wellingtonia*, such rapid growth, as they spread laterally in the same luxuriant manner.

Now, at my father's place, only about a mile and a half from this, a specimen of *Cupressus macrocarpa* of nearly the same size as mine, and which was in a most luxuriant state of growth, was killed, though it was protected on three sides by a house, walls, and trees, and the thermometer ranged a degree higher than mine here, but it was in a lower situation and near a river; whilst some plants of *Cupressus Lambertiana*, which I raised from seed at the same time as those before mentioned, were either killed or so much injured that they will never be worth anything.

From the above, and observations elsewhere, I gather one or two facts, probably well known to other observers, but which may be useful to those about to plant.

1st, That *Cupressus macrocarpa* will grow most luxuriantly in a stiff clay with a "good heart to it."

2nd, That it should not be planted, nor, indeed, any other half-hardy Conifer, in a low damp situation, or near a river.

3rd, That it should not be planted at the corner of a house, nor in any place where there is a strong draught, as this is even more deadly than severe frost.

I may add, that the only Conifers that I have tried that do not seem to thrive in clay, are the *Deodar* and *Pinus cembra*, the former especially looking very unhealthy, and making hardly any progress; the latter looks healthy, but grows very slowly. *Picea cephalonica* grows very well, but making early shoots, which are cut off by late frosts, it does not, therefore, make much progress here. *Wellingtonias* grow most luxuri-

* They are the same.

antly, as, I believe, they do almost everywhere, except in very shallow and poor soils, and I have some which I raised from cuttings, which it would be impossible to tell from seedlings, so symmetrical is their growth.—A SOMERSETSHIRE PARSON.

CATERPILLARS ON GOOSEBERRY BUSHES.

IN "Manures for the Many," gas ammoniacal liquor is highly spoken of as a manure; and in various parts of this Journal, from time to time, tan strewn underneath the bushes is recommended for the prevention of caterpillars. Gas ammoniacal liquor I know is a very dangerous agent for inexperienced persons to deal with. The way I propose to use it is as follows:—To sprinkle over a cartload of tan, say 10 cwt., and well mix in it 5 gallons of ammoniacal liquor; then to spread the tan so mixed under the bushes to the depth of 2 inches. Would this injure the trees, and do you think it would have the desired effect?—R. HAMMOND.

[We are decidedly of opinion that spreading tan as you propose will effectually protect the Gooseberry bushes from the ravages of caterpillars. It prevents the fly emerging from the soil where it is in the pupa state, and it prevents the caterpillars descending into the soil to assume the pupa form; for the insect in all its stages seems to have an antipathy to tan. The fumes of the ammoniacal liquor would tend to check the visits of the fly to deposit its eggs on the leaves. We think the proportions you propose are good, and would not injure the bushes.]

PROLIFEROUS FERNS.

I HAVE read somewhere that it takes a higher order of generalship to make a well-arranged and orderly retreat than to march on to an easy victory with drums beating and colours flying; but I have never yet heard of a general who appeared to relish recording his own defeat, and yet that anomalous position is now mine.

Having built up a theory on seemingly good foundations, I am now obliged to demolish it with the "stubborn facts" of a far better pteridologist than I can ever pretend to be, and at the same time I have to record my own defeat; yet there is something so innately beautiful in truth, that I cannot but be glad to have arrived at it even at the expense of a pet theory. Mr. Wollaston kindly allows me to state his experience of proliferous Ferns in general, which, it will be seen, sets at rest all doubt as to their not being proliferous in a wild state; but I had better give Mr. Wollaston's information in his own words.

"Believing as I do," writes Mr. Wollaston, "that Ferns in general have one common origin, it naturally follows that for the same reason that exotic Ferns are viviparous in numerous modified ways, so likewise are the British, varying in their prolific tendency according to habitat, climate, culture, &c."

This is, then, if I may so say, Mr. Wollaston's theory or reasoning, and it is borne out by the following fact:—

"I have found," says Mr. Wollaston, "at least a hundred plants of *Polystichum angulare* both normal and abnormal (one a normal form as long ago as 1855), that had bulbillæ on them in their wild state."

Mr. Wollaston then proceeds to the "possible causes of the development of bulbillæ" on *Polystichum angulare* (which, he says, he has found on the rachis of recent and one-year-old fronds), in these words:—"A moist atmosphere is almost indispensable for the development of bulbillæ; and coupled with heat, as in a forcing house, it is the greatest incentive.

"I do not agree in toto with 'FILIX-FEMINA,' that it is 'an effort of nature to throw off exuberant health' (see JOURNAL OF HORTICULTURE, Nov. 28th); but it is the nature of plants in general, and more especially of Ferns, to reproduce themselves in some way, and one of the ways is by bulbillæ. This is shown most strikingly if, by an accident, a Fern is trodden on or injured; it will then throw off numerous small plants, or, if at all bulbiferous, innumerable bulbillæ.

"Arrestation is another cause of viviparous growth—that is, if a frond of a Fern is broken off, or pierced by an insect, or imperfect, as in the abnormal growth of the marginate or interrupted varieties of *Scolopendrium vulgare*, one or more bulbilla may be seen. In the variety of *Scolopendrium vulgare* called *Wardii* I have seen more than one hundred young plants on one frond.

"It may not be generally known, although it has been pub-

lished before, that from each old frond of *Polystichum angulare*, *Scolopendrium vulgare*, and probably many other species, a young plant may be produced by taking the club-shaped portion of the stipes with a rootlet attached (each frond having at least one), and putting it into a pot of sandy peat with a little bottom heat.

"A damp atmosphere and arrestation of growth I believe to be the chief causes of the viviparous development of British Ferns."

After this evidence from so high an authority as Mr. Wollaston, I feel that there is nothing left for me to do but to retreat as gracefully as may be, conceding to Mr. Wollaston the honour of having settled beyond dispute that the capability of becoming proliferous is inherent in Ferns simply as Ferns. Thus I would say, Ferns have the power of reproducing themselves from seed as well as from bulbilla or buds, the development of this latter power being incidental to certain exciting causes not yet thoroughly understood. I would at the same time suggest that some better name than "bulbs," "buds," or "bulbilla" be given to the reproducing organ.

In the cultivation of proliferous Ferns my experience differs from that of Mr. Wollaston in so far as regards "arrestation" being a cause of viviparous growth. In those proliferous Ferns which I have under cultivation I find that the healthy fronds have the most bulbs.

I hope that all Fern hunters will look out for bulbilla on Ferns in their wild state, and make their success public as soon as possible.—FILIX-FEMINA.

IMPROVEMENTS IN BUILDINGS

AND STRUCTURES TO BE EMPLOYED FOR HORTICULTURAL PURPOSES.

A PATENT, entitled as above, has recently been obtained by a gentleman very favourably known as a fruit cultivator. The "Cylinder Vinery," described and figured at page 387 of our last volume, is constructed on the principle detailed in the following specification:—

"The object of this invention is principally to form glazed structures for protecting Vines, Pears, Peaches, Nectarines, Apricots, Figs, Strawberries, Potatoes, or other trees or plants, in such manner that the structures may readily be removed or the sheets of glass taken away from them at such times as they are not required for protecting the trees or plants. For this purpose I employ bars of wood in which grooves are formed for supporting the sheets or panes of glass, or it may be for supporting slates, and which bars are boiled in creosote or treated with other preserving agent to retard their decay; the sheets or panes of glass or slates are merely inserted into the grooves in the bars of wood, and are so held without putty being employed; the grooves are by preference made in all cases to pass diagonally into the bars from one or other of their edges, and I also form the grooves which are to receive the sheets of glass or slate wider at the bottom than at the mouth or entrance; this allows of a groove smaller at the mouth being employed than could otherwise be the case, as the wood at the mouth of the groove may spring back on to the glass after the edge of a pane of glass has been inserted into the groove; the grooves may be thus formed by first making a groove with a circular saw and then widening-out the bottom of the groove by a plough plane inclined to one side. The above plan also admits of turning circles.

"For forming a ridge roof I proceed as follows:—I drive posts into the earth at intervals along one side of the row of trees or plants, afterwards I measure-out the space to be covered, and drive along the opposite side of the row of trees or plants a similar row of posts, and affix to them a similar bar in which also a groove is formed leading from its upper edge nearest to the row of trees or plants. Along the centre between these two rows of bars I drive in a third row of posts which are to project a greater distance from the surface of the ground than the rows of posts on either side of them, and to the top of these central posts I affix a bar having formed in it two diagonal grooves which proceed from its two lowest edges; the grooves in the rows of bars so fixed in position serve to carry the sheets or panes of glass which are to glaze-over the space between the rows. To insert glass into the grooves the upper edge of each sheet of glass is first inserted into one of the grooves at the bottom of the upper central bar, and the lower edge of the sheet of glass is then dropped into the groove at the top of one of the outer bars to allow of the sheets of glass being thus shipped into the grooves; this is chiefly of use in inserting a new pane of glass, supposing there be a breakage at any time. The grooves in the upper central bar are made deeper than the grooves in the outer bars. On the north side of a structure slates may be used in a similar manner. To form upright walls or screens of glass or slate I drive into the ground at intervals apart from one another rectangular wooden bars which have been treated with creosote, as above mentioned, and which have had diagonal grooves formed along them

leading from two opposite angles. The bars or posts are driven into the ground in such manner that the grooves at the angles of one post shall come opposite the grooves at the angles of the posts next to it. The sheets of glass or slate are then slipped down the grooves and are so held in position. The posts may, if desired, be further secured by wire tightened by nut and screw at one end. In order to keep the glass (or slate used in the same manner on the north side) tight I insert a small cord (soaked in creosote) into the groove; I then place the glass or slate in the groove against this cord, and I tighten the whole work by means of a wire inserted through all the bars and screwed-up at one end. Screens of glass or slate thus constructed may be made into any shape required, being either made in straight lines, circles, squares, zig-zags, or otherwise; or in place of this what I call glass hurdles may be formed of iron uprights which are to be driven into the ground, and which carry grooved horizontal bars, into the groove of which the bottom and top edges of the sheets of glass are inserted. To form moveable lights for covering rows of Vines, Strawberries, or other trees or plants, I take two pieces of rectangular bar of some feet in length; I insert the glass (slate for the north side) into the groove of each bar, and draw the bars tightly to the glass by means of a stout wire with nut and screw at one end; if I wish to stiffen this tight I place two or three strips of sheet iron of the thickness of the glass, and screw the bars tightly against these irons.

"For growing Peaches, Nectarines, Grapes, or other fruit out of doors on walls I employ for this purpose a building or structure formed in the following manner:—On the north side I construct a slate wall (on the same principle as I have described for constructing a glass wall); about 3 feet in front of this slate wall I construct a glass wall 1 foot lower than the slate wall, against this glass wall I train fruit trees; when the sun shines on the slate the heat is thrown on to the trees on the glass wall, the heat being prevented rising from the slate wall by a foot or more of glass being inserted diagonally in the cap of the slate wall, forming a cave; my plan is then not only to give greater heat to the fruit and more light all round it, thus securing colour and flavour, sufficient air being admitted at the top to keep up a constant circulation, but also to prevent autumn rains falling in too great abundance on the roots and causing the plants to send out unfruitful wood; besides that, the expense of erecting a structure of this kind is only about two-thirds of that of a common brick wall, and the materials are not subject to become decayed."

NOVEMBER, 1867.

BEFORE the freshness of the impression has faded from the memory, it may be worth while to note some of the peculiar features of the weather in Guernsey during the above-named month for the purpose of comparison hereafter, more especially when the month of June again comes round.

These features are—1st, the very small amount of rainfall from the 1st to the 29th of the month; 2nd, the unnoted predominance of N.E. and S.E. winds; 3rd, the warmth of the first half of the month; and lastly, the slight indications of the presence of ozone.

The readings of the thermometer from the 1st to the 15th were, as it may be inferred, above the mean value; but on the morning of the 16th a strong gale from E.N.E. sprang up suddenly, and continued with more or less violence, though with slight variation in direction, until after midnight of the 18th. After this the temperature declined steadily, but not excessively, reducing the mean temperature of the whole month, however, to $1\frac{1}{2}^{\circ}$ below the average of years.

From the 18th to the 29th the weather, although gloomy, was pleasant and comparatively calm. Vegetation had received no check, there having been no hail showers and no frost; but on the morning of the 30th another severe gale arose, accompanied by rain to the amount of nearly 2 inches in the succeeding twenty-four hours. This was followed by very unseasonable weather during the whole of the first week of December. Compared with corresponding periods, the mean temperature of the air of these seven days was found to be considerably lower than it had been during the first week of any December for five and twenty years. The minimum thermometer, however, did not fall below 31° , indicating merely 1° of frost, and that of transient duration, when showers of sleet and melting snow were falling. This temporary frost does not seem to have inflicted much injury even on Pelargoniums and other tender plants—not so much so, indeed, as the severe gales without frost of the middle of November.

As a remark, it may be stated that the general stillness of the air, and the obscurity of sky noticed during the latter part of November, reminded many persons as well as myself of the atmospheric condition preceding a rather sharp shock of earthquake which was felt in this island on the 22nd of December, 1843. This shock, which is described somewhat in detail in the "Proceedings" of the Royal Society for the year 1844,

seems to have been associated with an eruption of Etna. No sign of vibration, however, was experienced here in November last during the period of stillness alluded to; but at that time the crater of Vesuvius is reported to have been in a state of great disturbance. Another shock of earthquake was felt in this island in April, 1853, and was concurrent with a violent eruption of Mount Hecla. These coincidences, although not, perhaps, of any importance, are curious nevertheless.—S. ELLIOTT HOSKINS.

CANADA AGAIN!

It is some time since I last sat down to pen a contribution to the columns of "our Journal," and I think I may truly be called an "occasional writer." It was "WILTSHIRE RECTOR'S" robin that stirred me to join the fraternity, and it will soon be time for master redbreast to carol again. I trust before old King Christmas comes to set foot again on my native land, and to see personally the genial Editors of our fireside companion, as also some of my brother quill-drivers.

In this part of the world we have just passed through a very extraordinary and discouraging season. Up to the middle of May we were deluged with rain, so that both agricultural and horticultural operations were quite set back. Since that time I think I may safely say that not one inch of rain has fallen until to-day (November 29th), in consequence of which our crops of all kinds have been quite a failure, with the exception of Apples: these, however, on account of the drought, have ripened so thoroughly on the trees, that we experience great difficulty in keeping them, even the later sorts now showing symptoms of immediate maturation.

The damp spring weather caused all the Peaches to cast their blossoms. Cherries were dried up by the after-drought: Pears much diminished in size, and a very light crop; Plums none. Strawberries and other small fruits were almost a total failure.

Vegetables, too, have suffered terribly, and my English varieties of the Potato are, as the Americans would say, "Small Potatoes, and few in a hill." The excessively dry weather was even too much for Maize and Tomatoes; the former in many cases being quite burned-up, and the latter a very short crop. I should say that we still find the Orange-field Tomato the earliest and best variety we have, the result of our experience thus coinciding with that of the Committee of the Royal Horticultural Society in the trial garden at Chiswick.

Little Gem Pea was, considering the season, simply grand. Advancer maintained its former excellence. These two varieties with us stand unrivalled, and by a succession of sowings Peas may be had all the season through.

The wells and streams in this vicinity have all given out, and for months the farmers for miles around have been engaged in drawing water in barrels from Lake Ontario. That person of undoubted veracity, "the oldest inhabitant," does not recollect such a season, and I sincerely hope I may never again experience another like it. Unless we should have a heavy rainfall before the ground freezes-up the result will really prove calamitous. On the Atlantic seaboard, not four hundred miles away, the summer was a wet one, and everything suffered from too much rain.—W. T. GOLDSMITH, *St. Catherine's, Ontario.*

ZONAL PELARGONIUMS AND ROSES

AT MR. WILLIAM PAUL'S NURSERIES, WALTHAM CROSS.

THE Zonal Pelargoniums, both with and without tricolor markings, seedlings as well as named varieties, which I saw at these nurseries, were especially beautiful; and the manner in which sports originate upon seedling plants, as there exemplified, interested me much.

Plants which as seedlings were perfectly green, save that a faint zone was distinguishable upon them, now and then broke forth into a variety of distinctly and beautifully marked shoots. The same plant would have on one side a shoot with foliage exactly resembling Mrs. Pollock or Lucy Grieve, and on the other something as bright as Countess of Kellie; whilst amongst all these leaves are constantly forming parti-colored ones, and others possessing many markings of great beauty. The object with such plants is to fix any sport which is likely to prove an advance in the right direction. With this view all simply green leaves are constantly pinched-off as they appear, those only being allowed to grow which by their distinct mark-

ings are likely to aid the attainment of the desired result, and eventually a shoot possessing an aggregate of the necessary brightly coloured leaves is obtained, and when obtained immediately removed and struck as a cutting. If needed, the former practice is repeated until the sport has become sufficiently fixed to take its place as a standard variety.

In the house specially devoted to these Pelargoniums, Mr. W. Paul has already two or three excellent novelties, of which, doubtless, we shall hear more in course of time. There is a very distinct and beautiful variety of the Oak-leaved Pelargonium. Perhaps I may best describe it by stating that the flower, though more striking and brighter-coloured, is not unlike that of the old Shrubland Rose variety. The plant is very much more free, dwarfer in habit, and more sweetly scented. It is named Waltham Ruby, I believe, and is suitable for pots, vases, and, indeed, for general decorative display.

In another house was a very fine stock of Ericas; hyemalis and amabilis being especially not ceable on account of their fine healthy condition. Amongst Epacris, Rubella and Ardensissima were very striking, being varieties with bright-coloured flowers. The Variegated Pampas Grass does admirably as a pot plant, and thus grown as a specimen contributes much to the general embellishment of a house containing other plants, such as Camellias and Azaleas, at this season. There is here a large stock of Camellias, home-worked, and, consequently, far superior for the cultivator than plants imported from the Continent.

The house devoted to Roses, and in which they are turned out of the pots into borders, still contained fine blooms of some of the most delicate Tea varieties. There is an especial beauty about the Rose when chilling winds tell it is passing away; and much is it to be wondered, therefore, that many more such simple structures are not raised for the purpose of securing blooms full of sweetness and beauty when all the plants without are leafless. *Maréchal Niel* and *Climbing Devonensis* are two varieties well adapted to this form of culture.—E.

KITCHEN GARDEN WALLS.

GARDEN walls serve as a fence, afford shelter, present a surface for training fruit trees upon, and accumulate heat. As a fence a wall 6 feet in height is sufficient; as regards shelter, the higher the wall is the better it effects the object sought; and as to the accumulation of heat, the higher the wall the greater is the amount of heat accumulated; whilst as a surface for training trees upon, it must follow that the higher the wall, the less necessity there will be for the annual topping and restriction of growth.

Peach trees upon a low wall do not in cold localities ripen their fruit nearly so well as upon a higher one. This is due to the surface of a high wall accumulating more of the heat from the sun, and the heat accumulated during the day is given out by the wall when the surrounding air is colder. Presuming a wall to be 6 feet in height, the sun's rays obstructed, or the cubic feet of air deprived of the solar heat, will only be one-fourth the amount of that where the wall is twice as high, or 12 feet. It is not to be understood that a wall 6 feet high will accumulate exactly one-fourth the heat that a wall 12 feet in height would do; but notwithstanding the various circumstances that would interfere with the accumulation of the heat, it is evident that a wall depriving a certain number of cubic feet of air of the sun's rays must secure to the unshaded portion a greater accumulation of heat, and give out a greater heat from the surface, than a wall depriving of the sun's rays only one-fourth that number of cubic feet of air. This will be readily understood by the annexed section of a wall (see next page), showing the effect of the sun's rays falling upon a wall of 6, 9, and 12 feet in height. The sun being at an elevation of 45°, *a, b, c*, will represent the shaded portion at the north side of a 6-foot wall; *b, d, e*, that of a 9-foot wall; and *b, f, g*, the shade caused to the north of a wall 12 feet in height.

It may be safely concluded that what holds good in respect to a south wall, will also exercise the same or an approximating influence with respect to east and west walls. High walls with east and west aspects have a greater heat accumulated in their immediate vicinity than low walls, and are better suited for the trees, besides securing to them more heat, and, consequently, a more certain ripening, and greater perfection of the fruit.

That this is not all theory, I mention a few facts coming under my own immediate observation, and which cannot but have been noticed by others. In the case of the wall on the north

side of a kitchen garden, 15 feet in height, the trees ripened their fruit a fortnight sooner than those upon the south wall, which was 10 feet in height. The wall to the north was sufficiently heated by the sun to ripen Grapes and Figs; but neither of these fruits against the south wall ripened perfectly. Peach, Nectarine, and Apriote trees against the latter did not produce nearly such good crops, the fruit did not always ripen thoroughly; and as to the flavour, it was so inferior to that from the north wall, that it was noticed at the dessert. The difference was not attributed to the difference in the height of the walls, but to the south wall's age—so old, indeed, that repointing was considered impracticable, and it was decided to take the wall down and rebuild it. The trees, mainly Peach and Nectarine, were in fine health, having entirely covered the wall, and their annual growths were being restrained, hence the wall was carried up 3 feet higher, or made 13 feet in height. The only object sought to be attained, so far as I am aware, by raising the wall, was to give a greater extent of surface for the training of the trees. No one expected any extension of crop beyond that likely to result from an extension of surface; but the crop was not only larger, finer in size and quality, but the flavour so altered for the better, that it was not known at table from which trees, whether from those against the north or south wall, the fruit had been gathered. The time, too, of ripening was marked by little difference between them. The greatest effect of the raising of the wall was that two Vines brought forth Grapes, and a Fig tree its Figs ripe and luscious.

That the difference was caused by raising the wall, is in some sort confirmed by the results of raising the east and west walls, the height of which was insufficient for the trees, these extending beyond it every year as much as 2 feet or more, all of which growth had to be cut away partially at the summer pruning, and again completely at the winter pruning. The result in this case was, that Pears that formerly on the same trees cracked and spotted, ceased to do so, and they were larger and better coloured.

I could give further illustrations of the greater certainty of crops, and of the finer quality of fruit grown by trees against high walls than against low ones; but the beneficial effects of high walls are so apparent, that any one having paid the slightest attention to the subject must have been impressed with the greater advantages afforded by them.

In cold localities high walls are not only desirable, but essential; for the fruit that would ripen against a low wall in a warm locality, will, in order to come to perfection, require a high wall in a cold one. In the south, walls 10 feet in height answer very well, and Peaches will, undoubtedly, ripen against walls of less height; but walls 12 feet in height are not too high for the southern parts of the kingdom, whilst for the east and west, and the least northerly counties, north and south walls of less than 10 feet would be practically of no great use. In elevated situations, and in the northern counties, walls 15 feet in height are not too high; indeed, they would be advantageous.

In disposing the walls in a garden, the wall to the north ought to be higher than all the others, except in cases where the area enclosed is extensive, then the walls may be of one uniform height. The area to be enclosed by walls being one acre, I would have a wall 15 feet in height to the north; the corresponding one to the south might be 12 feet, and the east and west walls of the same height as the south wall. Gardens of less extent than one acre may have a wall to the north of 15 feet. If the garden is less than half an acre the height to the north will not signify as to the wall shading the ground on the north side; but if the extent of ground is considerably less than half an acre, a high wall will look very unsightly. The height of the north wall in this case may be 12 or 13 feet, the south wall 10 feet or less, and the east and west walls will look well if of the mean height of the north and south walls. The north wall being 15 feet in height, the south, east, and west walls may be 12 feet in height. In the south of England they will answer if less in height; in the north they might be higher.

As to the direction of walls, that will be to some extent overruled by the ground; but where practicable (and it is so in the majority of cases), they should run north and south, east and west, and the nearer their ends point to the four cardinal points, the less waste there will be of surface. Care should be taken to give as great an extent of south wall as possible, that being secured by disposing the ground in the form of a parallelogram, the longest sides being on the north and south.

The walls that run east and west are the most valuable, as they afford one surface to the south, which is the best possible aspect, but one face must necessarily present itself to the north,

and this is of the least importance; but the superior results obtained from the southern side more than counterbalance the loss. Walls running north and south will have each a west and east aspect, and the first is the more desirable. The face of a wall looking north has a north aspect, and whatever point of the compass a wall presents its surface to at right angles, that is the aspect thereof.

As regards the materials of which walls are generally built—namely, bricks and stone, the first are the most suitable.

Bricks vary both in quality, softness, and hardness, and also in colour.

As to quality, bricks should have an even smooth surface, be of uniform thickness, length, and breadth, as if not so it is impossible to make good work with them.

With regard to hardness or softness, that depends upon the clay, and upon the burning. Some clay is so full of limestone as to cause the bricks after they are set to burst upon their becoming wet, and this produces an uneven surface, and such bricks, therefore, are not to be recommended for garden walls. Ordinary slop bricks if free from limestone are good, and being well burned and made quite hard, are excellent for a wall. If badly burned they absorb too much moisture, and besides being subject to injury from frost, very much encourage the growth of moss, and soft bricks in this respect often become very unsightly. Fire bricks make excellent garden walls, but those which are white are quite as liable to moss as soft slop bricks; indeed, well-burned slop bricks are superior to badly-burned white fire bricks. Hard-burned fire bricks, when the burning is to the extent of glazing them, are not desirable for garden walls, as they absorb heat but slowly. Some idea may be formed of the hardness of the burning of a brick by placing one in a bucket and pouring over it a pint of water. If soft it will absorb it all, and even more, whilst a hard-burned brick will not do more than absorb two-thirds of a pint of water. The latter will stand any weather, and such only should be selected. A well-burned fire brick will absorb nearly, if not quite as much water as slop bricks, but it requires twice the length of time to do it, and it retains the water absorbed a much greater length of time. Well-burned bricks, then, should be used in the construction of garden walls, but the extreme of hardness is as much to be avoided as the opposite extreme of softness. A good hard ringing brick is the proper sort.

As to colour, very dark coloured bricks, as blue fire bricks, or blue bricks of any sort, are not good, for, from their near approach to black, they become hot during sunny weather, in consequence of their absorbing the heat instead of reflecting it as white does, and trees against them are unduly excited, and rendered more susceptible of cold, and, therefore, a check is given when sunless weather intervenes. The blossoms of trees upon dark-coloured walls open earlier than against either red or white; but the fruit does not ripen any earlier. The forwarding of the blossoms is no advantage, but the contrary in our climate. White has been highly spoken of as the best colour for a wall, but that reflects more of the sun's rays than any other colour, and it, of course, absorbs less heat. Red bricks are great absorbers of heat, and of moisture also, and the colour is glaring.

Pale-coloured bricks are best, but any light-coloured bricks will prove eligible, preference being given to them over dark shades.

Stone is an excellent material for garden walls, but the stones should not be large, as in that case it is difficult to train the trees. The courses should be regular, and ought not to exceed 6½ inches, or two courses of bricks when set, and this will be found a convenient distance for the training of the trees. If the courses are irregular, and the stones large, to have a well-trained tree the wall must be wired longitudinally, or have a wire trellis fixed against it, which is an expense that might, by a little contrivance at the time of putting up the wall, be saved.—G. ABBEY.

(To be continued.)

PEARS.

WE propose, for facilitating identification, to publish outline full-sized portraits of the chief varieties of our hardy fruits. We commence with the Pears. Our notes upon each variety will be very brief, and those of our readers who wish for detailed descriptions can refer to Dr. Hogg's "Fruit Manual."

1. ACHAN.—This is a truly north-country Pear, for though

1. Achan.

2. Adam.

delicious in Scotland, it is of no merit, though much larger, when grown in our southern counties. It is believed to be a native of Norway, and was shown under the name of the Bouchrefin, at the International Fruit Show of 1862, in a collection of Norwegian fruits. Ripe in November.—(*Fruit Manual*, p. 237.)

2. ADAM.—An inferior variety; speedily decaying at the core. Ripe at the end of October.—(*Fruit Manual*, p. 237.)

3. ALEXANDRE BIVERT.—A first-rate dessert fruit, raised by M. Berckmans, and named by him, in 1848, in honour of M. Alexandre Bivert, the Belgian pomologist. Ripe from December to February.—(*Fruit Manual*, p. 238.)

3. Alexandre Bivert.

4. ALEXANDRE LAMBRÉ.—Raised by M. Van Mons, and first fruited in 1844. It was named in honour of the grandfather

4. Alexandre Lambré.

of M. Bivert, an amateur arboriculturist. Fruit rarely of any merit in this country. Ripe from December to February.—(*Fruit Manual*, p. 238.)

NOTES AND GLEANINGS.

At the annual dinner of the Society of the Associated Seed Merchants of London, which recently took place at the Lenden Tavern, a handsome silver-gilt dessert service was presented to Mr. DANIEL NASH, as a testimonial of the high respect in which he is held by the Association, over which he has presided for a period of twenty-one years. The service consisted of a centre plateau and four corner pieces, each piece having emblematical figures in frosted silver, each figure mounted on a silver-gilt base, representing the four operations of agriculture—ploughing, sowing, reaping, and thrashing. The plateau bore the following inscription:—"Presented to Daniel Nash, Esq., by the members of the London Seed Trade, as a token of their esteem and appreciation of his services. December, 1867." Mr. Nash is the head of the well-known firm Minier, Nash, & Nash, which has for a period of nearly two centuries held a high place in the wholesale seed trade.

WORK FOR THE WEEK.

KITCHEN GARDEN.

ALL unoccupied ground ought to have been turned up by rough digging, trenching, or ridging, regulating these operations according to the character of the soil, and the nature of preceding and contemplated future crops. *Artichokes*, protect with any loose litter; also, *Asparagus*, *Sea-kale*, and *Rhubarb*, not that the last three will be injured by frost, but they will come in much earlier if the ground is not cooled to a low temperature. *Celery*, defend it from frost. It will keep good for a considerable time if taken up with balls, placed upright in rows in a shed, and clean dry straw put between the rows so that the heads may not touch each other. *Cauliflowers*, keep a sharp look-out after the plants in frames or under hand-lights, and those fit for use, as well as *Endive*, *Lettuces*, and *Radishes* in cold frames or turf pits, protecting those in the latter with straw or reed covers neatly made, or with hurdles thatched with straw or spruce branches. *Peas*, if not already done seize the earliest opportunity of mild weather to sow the first crop. *Ringleader*, *Dillistone's Prolific*, or *Dickson's First and Best* are suitable varieties. *Broad Beans*, sow *Early Mazagan*, or *Early Longpod*, choosing for the main crop such established early varieties, and only small quantities of these sorts the superiority of which is not sufficiently tested.

FRUIT GARDEN.

As to pruning, nailing, and planting, it is always advisable to be as forward as possible with these operations before Christmas. Protect newly planted trees with mulching. The wood of Peach trees will not be over-well ripened this season in unfavourable situations, and more especially in the case of these trees that suffered greatly from frost last January and February. The late frost, by checking vegetation, may help to ward-off such another disaster. All the young shoots of Peach and Apricot trees should have been unnailed some time ago. In consequence of being freely exposed on all sides the shoots would be better hardened, and from not being contiguous to the wall they would not be so easily excited, nor in so much danger of having their sap-vessels burst by severe frosts. In addition to this, the stems might be bound round, not over-closely, with hard-twisted straw bands, and a little long litter thrown over the border to the width of 4 or 5 feet. This is an excellent opportunity for moving soil, turning composts, and wheeling manure. Do not forget a little of the latter as a mulching or top-dressing to Strawberry-beds, if very superior fruit are desired next season. Standard Apple trees, if not already attended to, may now be pruned, taking care to cut out all cross branches. Gooseberries and Currants if not previously pruned may now be gone over, so as to allow the ground to be dug amongst them.

FLOWER GARDEN.

After the late frost and snow but little can be done here at present except where alterations are going on, and then the trenching of ground for planting may be proceeded with. Beds containing autumn-sown annuals would be the better of a few branches of evergreens stuck into them to shade the plants

from bright sunshine after frost, and to protect them from drying winds.

GREENHOUSE AND CONSERVATORY.

Of all plant houses the conservatory requires the smallest quantity of air in winter. In order to keep down dust, so injurious to plants in winter, the paths should not be swept when they are quite dry. Gardeners are often compelled to make use of the engine, even in winter, to cleanse the leaves. Very little water will do here now, and that should be 9° or 10° warmer than the general temperature of the house, which may be about 50°. The temperature of the greenhouse should not be raised much above 40° now. The watering ought to be finished early in the day, and the plants should be constantly looked-over to keep them free from dead leaves, insects, or mildew in the pots.

STOVE.

The temperature of this house should not exceed 60° by fire heat, and a fall of 10° may be allowed at night in very cold weather. Although all plants now at rest should be kept comparatively dry, they will require to be looked-over daily to see that they do not suffer from want of water, particularly those nearest the pipes or flues. Orchids may be potted, tied-up to logs, or fitted into wire baskets at any time when little can be done in the open air, but they need not be watered or induced to grow for a long time. This is a good time to prune and regulate the heads of the specimen plants. Many, such as *Justicias*, *Poinsettias*, *Apelandras*, &c., had better now be cut-down altogether and kept dry for a few weeks. If you have a good stock of *Euphorbia jacquiniellora*, cut down some plants of it also. This will enable them to make an earlier growth, and come into flower three weeks sooner next winter. This treatment equally applies to *Justicia speciosa*, and *Eranthemum pulchellum*, and, no doubt, to all our winter-flowering plants. Look over *Gloxinias* and *Gesneras* on the dry shelves, and start a few of each into growth, to produce a succession of flowers.

FORCING PIT.

It is only necessary to remark, that where forced flowers are in great request two divisions are necessary; one for such hardy plants as do not succeed in a high temperature, the other, with means for bottom heat, for *Gardenias* and other stove plants. Almost all plants, however, in forcing are benefited by a mild bottom heat.

PITS AND FRAMES.

Of all plant structures these have become of late years the most important. Everything, from the finest Heath to the humblest Alpine, finds a ready asylum in them during the winter. They require the utmost attention at the present time; a slimy green pot, a speck of mouldiness on the surface, or even a decayed leaf, if not instantly removed, may be the ruin of the most favourite plant. Very little water will be required here for some time. See that ample covering is ready for use during the long cold nights. A multitude of half-hardy plants may be kept in these without any means of artificial heating, but at the outset, notwithstanding all care, some of them may be lost. Deaths, however, will occur in the best plant houses. The young stock of plants in these structures is in a growing state, and, therefore, will require to be securely guarded against frost, but give them all the air and light possible on fine days, and keep them from mildew and moisture. Where *Hydrangeas* are required to turn into beds in the flower garden in April and May, they must now be put into the forcing house.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Much that was intended to be done remains still undone, and in most departments we have chiefly confined ourselves to keeping all going on in regular routine, aiming rather at having all right than at doing much fresh work. As mind and body become more settled we shall gain all the advantages ere long of a little relaxation. After much observation and personal experience we have come to the conclusion that the benefit from cessation from or change in labour—in other words, having so many hours or days as a holiday, is not so much seen at the time as afterwards. Even looked at in the lowest sense in which we can well regard it, the amount of labour to be obtained from mere physical power, less or more regulated by mind, the amount of the work performed will at first be rather less after a holiday than before; but in a few days the effects of the change and the relaxation begin to appear, and then,

provided these holidays do not come too often, we have no doubt that they tell even beneficially on the side of the employer of labour, both as respects the quantity and the quality of the work done. A day or two now and then, in the way of cessation from usual labour, is anything but lost time, as fresh energy and a fresh stimulus to exertion are thus supplied.

Vegetables, forced and otherwise, received much the same attention as has been detailed in previous weeks' notices. We shall just refer to a few matters now demanding attention.

Collecting Tree Leaves.—It is best, if possible, to collect these when rather dry, as then they may remain a long time in a heap, will heat and waste but little, and can always be made to ferment and heat sweetly by giving them a little water. In many places, however, they must be collected in any condition, and scarcely at all until the game-shooting season is over; and if for present or spring use the wet condition of the leaves is of less consequence, only when placed in a heap they will soon rot. They might, therefore, as well be giving out their heat as not for the forwarding of early vegetables where glass or other protection can be given, such as for Potatoes, Radishes, Lettuces, Carrots, Turnips, Asparagus, Rhubarb, and Sea-kale, which last may be had in any place where a heat of 60°, or more, and darkness, can be secured. Leaves when raked-up damp will soon ferment, and may, therefore, be made into beds for such purposes at once.

Methods.—When a greater heat is required, as for Cucumbers, &c., it is not easy to obtain enough of bottom heat and top heat at this season from tree leaves alone, unless, indeed, the bed is very large, and, therefore, it is advisable to have at least one-half of fermented stable manure along with the leaves. Those who are particular in sweetening such stable manure thoroughly before using it, should turn it several times in the course of three weeks, turning the sides into the centre and the top to the bottom, and watering any that appears dry, until all becomes of a darkish appearance, and so sweet that the moisture that rises from it, when condensed against an iron plate, or a square of glass, shall be not yellow-tinged, but as clear as a dewdrop. This sweetening will be hastened by mixing the dung with damp tree leaves; but where economy in material is an object, we would not mix until the last turning, as, if done at first with fresh dung, the leaves will be considerably wasted before the dung is sweetened. For lastly-made and very lasting, and therefore economical beds, we prefer to have the dung as much heated as to be half sweetened, and then cover that with a foot of fresh sweet tree leaves, through which no deleterious steam will pass. This plan saves material and time, and the beds when thus well made last and keep a regular heat for a long time, and if made large enough need little or nothing in the way of linings all the spring and summer. When we have a range of frames thus to supply with fermenting material, and can only manage a two or a three-light box at a time, we generally make the first bed in the centre, and then the beds on each side help to throw fresh energy into the heating powers of the first. By means of a few drain tiles set upright in the beds we can always keep the lower stratum slowly fermenting and decomposing, by adding air and moisture to it as wanted. Where hot-water pits or houses exist in plenty there will be less need for these dung beds; but they are of great benefit to the garden when the summer crops are all gone, and they can be taken to the ground as valuable dressings. Many have found out that it is possible to have too much of improved modes of heating when little else can be had for the kitchen garden, except the remains of the vegetables grown in it, and such will not long be sufficient in supplying a closely cropped garden.

Mushroom-bed Dung.—The remains of Mushroom beds are first-rate dressings for almost anything, and especially for flower beds; the material is generally so light, and the greater part of the strength is gone. We have for many years found it an excellent top-dressing for Kidney Beans in pots, and at one time we used it largely for Cucumbers in pots and boxes as thin top-dressings, putting on another thin dressing as the roots came through the last. It is also very useful for top-dressing orchard-house trees in pots during the summer. But for the corn growing, we would not mind fresh droppings for this purpose if there were a little of this decayed used-up Mushroom dung next the surface of the soil. For all these purposes, however, we like such wasted Mushroom dung to be rather thinly spread out of doors at first, before it is thrown into a heap to keep it dry, in order that cold and damp weather may destroy what active spawn may be left.

Mushroom spawn is almost as bad as any other fungus when

it takes possession of a place where it is not wanted. We have seen borders for fruit trees much injured by Mushroom spawn, and we have found plants and trees much injured until the spawn was all destroyed by strong fresh lime-watering. Hardly any of the Mushroom tribe will succeed or grow when treated with quicklime under any circumstances.

Preparing for Mushroom Beds.—In summer there is no difficulty in doing this, but there is more trouble in obtaining materials for a bed in winter. We have already several times stated how we have used almost every possible fermenting material for such beds. Provided we could obtain a few inches of good horse droppings, or good, sweet, hotbed dung for the surface, we have had many fine beds made with tree leaves, with a few inches of such rich dressings on the surface; but for all shallow beds on platforms, shelves, or even in moveable boxes and large pots, we prefer horse droppings with about a third of short dry litter, and from a sixth to an eighth of dry fibrous loam mixed with it. The nearer the droppings are being sufficiently dried—that is, to be neither wet nor dry, without heating much, the greater will be the nutritive qualities left for the support of the Mushrooms; and it is comparatively easy to secure this dryness without much heating in the summer months. There are no means in open sheds to dry such materials now without throwing them into a heap to ferment. They will soon dry sufficiently if the droppings were collected at the stable; but when they must be shaken-out from dung that has lain out of doors, they will often be so wet as to rot when heated, instead of drying, and in such a case we have cut dry straw and mixed with the materials to great advantage. When thus piled up in a heap from a week to a fortnight, the inside of the heap will have a dry whitish aspect; and though we have lost much of the nutritive qualities, we are forced to make that sacrifice to secure the amount of dryness which will secure a long and continuous heat from the materials when firmly beaten together in a bed. If damper, the heat would be apt to be too strong and not lasting, and the spawn dislikes damp ground to run in. When our beds have been damper than we liked them, we have had good crops by inserting each piece of spawn in a good handful of short dryish litter before fixing it in the bed. The general dampness of the bed then acted much the same as a casing of damp cow dung over a dryish bed—a plan, however, not to be adopted by those who dislike very thick succulent Mushrooms.

Draining.—No better time and weather could be found for this work, and in gardens it can rarely be effected except in the dull days of winter. It is hardly worth while draining if the drains cannot be made from 3 to 4 feet deep. We have seen much draining done with the common garden spades; but wherever a considerable amount of work is to be done, even a week or two of such work, it will always be money saved to procure a set or two of draining tools, so that the drain may be easily made like the letter V, and the round drain tile easily deposited in the acute angle at the base. If the cuttings of Blackthorn, &c., can be had, a good layer of these above the tiles will greatly assist them. We have helped to examine such drains filled for a foot in depth with Thorns alone, that worked well after being deposited for a score of years; and even then, except close to the outlet, they were remarkably fresh. It is always well, however, to have tiles if to be had.

For mere surface water the drains may be much shallower, but they will exercise but little influence in the culture of the soil. We have known some cases, however, in which all the work of draining was next to labour thrown away; and therefore it would be advisable to make sure if the ground really needed draining. We recollect of a case where the soil was a rather stiff loam, resting about 2 feet from the surface on what was considered to be a stiff clay—just such a soil as was supposed would be much improved by draining. A good outfall was obtained in the neighbourhood of a running brook, and the drains were made from 12 to 18 inches deep in the clay; but the wonder was that with the fall, &c., scarcely any water ran out of the drains. In fact, the draining was found almost useless work. Holes were made 3, 4, and 5 feet deep, and yet the latter seldom retained water long even in the winter months. The truth came out that the supposed clay was plentifully commingled with marl, as proved by the action of acids, and the extra moisture escaped easily by the veins of clayey marl. Making a few holes involves no great trouble, and may well be done before a great drainage work is commenced. If the subsoil is so open that the water passes freely, we may rest assured that such moisture rising again in the shape of vapour will rather be relished by the roots of plants in summer. If water

will not stand at a good depth, we can hardly have the surface soil too moist, unless there is some intercepting material between the surface and the subsoil.

Digging, Trenching, and Ridging have not with us received, as yet, the attention they ought to have had, but we so far please ourselves with the thought, that the surface of the ground has been pretty well frozen, and we rather like it to be so, and thawed again, before we turn the surface down to the bottom of the trench in ridging. Nevertheless, we would have liked to have had more soil ridged-up.

Frosty mornings furnished good opportunities for wheeling manure, rubbish heaps, burnt earth, weeds, &c. After breaking the dung fine, thrown over Asparagus rows, we gave a good dressing from a heap formed chiefly of burnt prunings, weeds, and edging-parings, which will only be less beneficial than a sprinkling of salt, whilst it will secure to our stiff soil a lighter surface.

Sea-kale and Rhubarb.—For the main crops out of doors we prefer planting in well-trenched, well-aired soil, in spring, just after the heads or buds begin to move, using young plants for Sea-kale, and either young plants or dividing the roots for Rhubarb. Large stools are benefited in their produce when divided into two or three pieces; but as spring generally brings enough of work with it, such work may also be done now with advantage, and so may Asparagus be planted in a mild day, when there is no danger of the tender fibres being dried-up or injured. The best time to transplant this vegetable is when the shoots have grown some 3 inches in length; then scarcely a single plant fails, whilst what we used to plant in the winter did not grow quite so regularly.

Horseradish.—This we consider to be always best, and fit for use right up to the core, when it is transplanted every few years, a few rows at a time. The worst of it is, the difficulty of eradicating it from a piece of ground where it has once been planted. The most secure mode is to pick up every bit as it appears, and especially never to allow a leaf to grow. Few plants will long retain healthy roots if no leaves be allowed to grow. Constant cutting will beat the Nettle, the Thistle, and even the more dread white-rooted Convolvulus. In cold weather the easily-grown Horseradish might be more used than it is. It would to many a working man be little less serviceable than the once famed "curry powder."

FRUIT GARDEN.

Here the weather and other circumstances have prevented us doing much out of doors; and in-doors the chief work has been attending to the fruit room, taking out all specked fruit, looking over Grapes, which have kept well, but are becoming thin, and pruning and cleaning fruit trees in vinerias and orchard houses. We had intended having some work with

Vine Borders, but as yet, have been unable to do anything. Many questions have been put to us since we detailed the simple plan of border-making, or rather no border-making, at Messrs. Lane's, of Berkhamstead. Before going to great expense in draining, &c., it would be well to ascertain whether there would be standing water; and if the natural soil is good, most likely the addition of some lime rubbish, and some boiled broken bones will be all that is necessary to secure fine Grapes. We should like to have fresh fibrous turf and bones, and use the means to keep the soil open, as it all soon becomes close here if left to itself. In all such cases, especially for early work, much depends on having canvas or boards fixed tile or slate fashion, to keep the late autumn and winter rains off—a practice which has done wonders in many cases, though we have seldom been able to resort to it ourselves, and, therefore, have had to be content with makeshifts.

ORNAMENTAL DEPARTMENT.

When the day was at all open, proceeded with moving trees and shrubs, taking care to place them in mellow soil before the roots were injured by frost, or the soil caked. Cleaned and rolled pleasure grounds, forwarded bulbs and shrubs, including Roses, for blooming. Put a lot of Cinerarias into a drier place to open their blooms more freely. Shifted Pelargoniums and other plants, and potted some stove plants in small pots. Damped the floor and stage of the cool house in frosty days, but kept the tops of the plants, Ferns, Mosses, &c., dry, and in cold days preferred a safe low temperature to making fires, to give much cold air. Gave as little water to all greenhouse plants as possible, so as to keep them healthy; but took care that Camellias, Cinerarias, Primulas, &c., did not suffer from dryness. Epacris stand a much closer and moister atmosphere than the Erica tribe, and these last must have more air and less heat.—R. F.

COVENT GARDEN MARKET.—JANUARY 1.

Roots articles of produce have made a slight advance; but all the rest remain nearly the same. Pears are now becoming rather scarce, and comprise Glou Morqean, Ne Plus Meuris, and Crasanne. Good dessert Apples are in better request. The Potato trade is stationary; some fine samples of Regents have come to hand during the past week.

TRADE CATALOGUES RECEIVED.

James Veitch & Sons, Royal Exotic Nursery, King's Road Chelsea, London, S.W.—*Catalogue of Hardy Trees, Shrubs Coniferae, &c.—Catalogue of Garden and Flower Seeds.—List of Gladioli.*

TO CORRESPONDENTS.

. We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

MAUD.—Let us know where you wish us to send. We reciprocate all good wishes.

PEAT CHARCOAL.—"A Subscriber" wishes to know how this can be made, so that he can use it in Hay's stove. We think that coke might be burnt in it if a chimney tube were attached to the stove.

FOWLER'S INSECTICIDE (S.).—It is advertised in our number published on the 5th of December.

HULLETT AGAIN.—"The writer of this is one of those who had the ill luck [indiscretion?] last spring of purchasing some of Mr. Hullett's Chinese Sugar Grass seed to the amount of 2s. Not a single blade came up. Has any one heard of any coming up, or of a single success?"—H. C. S. G.

BURNING SULPHUR TO DESTROY INSECTS (Q. R.).—It is quite true that to one correspondent we advised this and to another deprecated the practice; but each reply was justified by the circumstances. In the one the wood and buds of the Vines were well ripened and quite dormant; in the other the shoots of the fruit trees were not well ripened. In the latter case we objected to the use of burning sulphur.

FLUELESS STOVES (J. B.).—No stove without a flue or chimney can be used among plants. This has been proved frequently. Our correspondent wishes to know if the Royal Vineyard Grape has been found to set its berries well.

WINDOW GARDENING (Easton Park).—If you enclose ten postage stamps with your address, and order "Window Gardening for the Many," it shall be sent to you post free from our office.

PRUNING ROSES (J. Green, Guernsey).—"Three feet is closer than I should have cut Anna Alexieff with 9-foot-long shoots. Supposing the plant to have five such shoots, I should have cut the five shoots to 6 feet, 5 feet, 4 feet, 3 feet, and 2 feet. It is not good to cut such strong shoots

of strong-growing kinds very short; it only promotes strong and blind growth. If the whole wood of any plant is bad, it is best to cut it down and look out for better growths, otherwise I never cut down Roses on the Manetti. Roses on the Briar require to be pruned more or less closely, according to their rate of growth, annually. The Manetti stock supplies such tides of sap that it requires a good volume of wood ready to take it off.—W. F. RADCLIFFE."

PRUNING HYBRID PERPETUAL ROSES (C. O.).—"You do not say whether the Roses are on a Briar, on a Manetti stock, or on their own roots. If they are on a Briar cut out all useless wood at once, and in March, when the weather is mild, the main stems may be cut to two, three, or four eyes, according to circumstances. Roses on the Manetti or on their own roots may be thinned-out now, and cut at once, or in March; or they may be allowed to form all their buds, and be thinned-out, and some of the tree be cut back in May. All my ground plants are skeletonised, and will want but little more cutting. I thin-out my bushes after blooming is over to let in sun and air, to harden the bark, and to help to mature the wood.—W. F. RADCLIFFE."

ROSES FOR NORTH FRONT OF A HOUSE (C. W. M.).—"The aspect being north, the Roses must be hardy, grow quickly, and bloom freely. The following would do well, I should think:—*Crimson*: Général Jacqueminot, Madame Louise Carique. *Yellow*: Mademoiselle Aristide, called also Madame Schultz, a very strong grower, not very double, but the hardest yellow known; and *Gloire de Dijon*. *Rose-coloured*: Anna Alexieff and Baronne Prevost. *Cerise*: Jules Margottin. *Dark Purple*: *Crimson*: Duc de Cazes.—W. F. RADCLIFFE."

ROSES (Ormskirk).—"I, Panachée d'Orléans is a pretty, semi-double, striped rose. 2, Ardoise de Lyon, slaty crimson; a hard opener, worthless. 3, Madame Standish, a pretty, small, pale pink Rose. 4, Name not readable; if intended for Madame Desprez, it is lilac rose. 5, Madame de Trotter is cherry rose, fine colour, but given to green eyes; the plant is a strong grower, and never blooms a second time. Cut it down, and had some favourite on the new stems. My finest Lord Macaulay is on stems of this variety. 6, Frederick II. is a fine crimson, purple pole Rose, Hybrid Bourne, semi-double. 7, Baronne Halle, deep red, much given to mildew, for which cause I gave up it and *Géant des Batailles*. It is the best of the lot, and very fine. 8, François Arago, crimson purple; good. 9, Salvator Rosa, red. 10, Richard Smith, semi-double, blooms in large corymbs; a good and continuous bloomer, useful to cut up for bouquets; it is crimson purple. As the Roses are in your garden, bloom them all the next season, and you will see which will please you and which should be discarded. 7 and 8 are all that are retained in select catalogues. As we have no striped Hybrid Perpetuals I should select I. Pavillon de Pregny, a new Rose, is a very pretty, variegated, abundant-blooming kind, adapted for garden ornamentation and bouquet purposes.—W. F. RADCLIFFE."

NOTICE TO LEAVE (Sittingbourne).—You ask, "What notice in general should be taken by and given to a gardener living on the place and paid weekly, without any previous agreement as to notice?" "Living on the place" does not give a clear idea. If living in the house, though paid weekly, a month's notice is generally given. If you live in a cottage on the estate, and not connected with the establishment, the fact of your being paid weekly would make you, we presume, a weekly servant, and, we think, you could not claim more than a week's notice, as nothing was said on the subject at the time of agreement, otherwise it is usual in the case of gardeners to give and receive a month's notice; but we have known cases in which that notice was not given. There are rules of courtesy, consideration, and kindness more binding than custom, and they who break these rules will generally suffer for it. The gardener will be wise not to err in this respect, however great the provocation. There are cases, also, where staying a month would be little better than a punishment.

BEDDING ANNUALS (A Cottager).—You will find a full descriptive list in our number 396, published on the 7th of last February.

YOUNG VINES BLEEDING (W. F.).—The bleeding now when cut is owing to the free growth, the good border, the action of the roots still, and consequently the sap still in motion and no outlet by leaves. Allow the house to be cooled-down with a little frost, the border also to be exposed, and in a few weeks you may prune without any risk of bleeding. If it troubles you even then, use Thomson's styptic. We once saw a viney, the Vines bleeding when cut at Christmas, and the leaves all off a month previously; but in this case the Vine borders had been made late in spring, and so much grassy sods and bones had been used, that there was a considerable heat in the border in November.

VINES FOR FORCING (Rusticus).—You require fourteen, and we recommend you to procure four Muscat of Alexandria, three Alicante, three West's St. Peter's, two Muscat Hamburg grafted on Black Hamburg, two Lady Downe's. These are recommended on the supposition that you want to force Grapes for a late crop. If you require them for early forcing you cannot do better than have four Black Hamburg, two Black Prince, three Royal Muscadine, two Salomon's Frontignan, one Mrs. Pince's Black Muscat, one Black Frontignan, one Grizzly Frontignan.

DISSOLVING BONES (T. M. N.).—Put a layer, 1 inch deep, of broken bones, and sprinkle caustic potash over them and among them; the potash can be mixed with the bones as they are put into the vessel where they are to be dissolved. Caustic potash is not soda. It can be usually bought at druggists' or drysalers'. It is rather dearer than washing soda.

HEATING BY STOVE FLUES (A Bucks Bee-keeper).—Refer to some of our back numbers, in which are answers to correspondents as to heating by a stove's flues. We are not sure of the size of your small house; but we have kept the frost of this season as yet out of an orchard house, 75 feet long, by means of an iron stove. Now, first, you will not succeed by placing your iron stove either inside your house or outside the house and taking a flue from it, either through the house or returning from it; but you may heat the house well by such a flue and a common furnace placed outside the house, and in such a manner that the bars of the furnace are 15 inches at least lower than the bottom of your flue. If, for your small house, you merely want to keep out frost, then your iron stove set in the house will answer admirably, provided you have a horizontal pipe from it not more than from 18 to 24 inches long, and then an upright pipe passing through the glass roof, which is most easily managed by placing a zinc square with a hole in it instead of a glass one; or your stove might stand against the back wall, and the pipe go through the wall. There need be no trouble with smoke, dust, &c., if the directions

given in the answers referred to are attended to. The top of the stove being flat will enable you to set a pan of water on it when much heat is wanted. The draught must be regulated by the asphit door.

UTILISING GARDEN FRAMES (Ch.).—Your cheapest way to make your six lights of frames more useful, would be to make a pit, say from 18 inches to 24 inches deep all round, and of a width to suit your frames standing close on the walls, and the best way to heat such a place would be by a 9-inch flue passing through it in front and along the ends, or a 6-inch flue going round it and coming to the chimney. By such a mode, or without the frames, and having a pit 30 feet long, and the back wall of the pit, if 6 feet wide, 18 inches higher than the front, and heated the same way, you could keep and grow many things, more especially if you had a movable stage inside to place the pots at a greater or less distance from the glass. You could heat such a place well with a small iron stove, but then you could not force so well. With one or more divisions you could give each its suitable temperature, and at an early period you could use fermenting material as in a hotbed. Of course hot water, by Musset's plan or otherwise, would be best; but do as you will, it is always expensive for small places unless the simplest modes are used.

WINTER TREATMENT OF VIOLA CORNUTA (Fred.).—It would be well to remove any long straggling stems now, and to give a mulching of half-rotten leaves, which will act as a protection. Place it round but not over the plants, and in spring point it in with a fork, removing at the same time any decayed stems or irregular growths, so as to give the plants a neat appearance. They will bloom finely in spring, and much earlier than young plants. If you require more stock you may take up the old plants in spring and divide, or take off the rooted offsets, which last will give you a later bloom if planted in good rich soil and well watered in dry weather.

PANSIES IN WINTER (Idem).—The old long stems which have flowered ought to have been cut off early in autumn, but you may do it now, and give a top-dressing of rich compost, say turfy loam and rotten manure in equal parts, the ground having previously been cleared of weeds and the surface of the beds stirred, but not deeply, with a fork between the plants. The top-dressing should be put between the plants and close to them, and it may be an inch thick.

CERASTIUM TMENTOSUM EDGINGS (Idem).—Last year's edgings will do for this if they are not old; but if old it would be preferable to take them up in March and replant. If you leave the old edgings, reduce them in spring to the required width, and cut in the shoots closely, so that fresh shoots may be produced. On the freshness of these the beauty of the edgings in a great measure depends.

SHRUBS FOR CHURCHYARD DEPAUPERED BY SHEEP (An Old Subscriber).—You may plant the common and variegated Hollies largely, Evergreen Oak, and standard Portugal Laurel, which we have seen in places depaupered by sheep; but the shrubs were of good size when planted, and had stems high enough to place the foliage beyond the reach of the sheep. Most of the Conifers would succeed, providing they were of good size and the upper part beyond the reach of the sheep.

COMPOST FOR CYCAS REVOLUTA AND LATANIA BORBONICA (A. B. J.).—They succeed in a compost of two-thirds turfy loam, that from rotten turves being best, and one-third turfy peat, adding sand liberally. The compost should be used rough, merely chopping it with a spade, or breaking it with the hand, which is best. Good drainage should be given. Good peat can be obtained in so many districts, that we are unable to say from whence the best comes. Consult a nurseryman or gardener in your neighbourhood who is successful in plant culture.

COVERING VINE BORDER WITH GLASS (Beginner).—Instead of manuring the border heavily in autumn, we would, as the roots are not to be found, or with difficulty, remove the soil from the border to as great a depth as practicable without disturbing them, and take it away. We would then point-over the border, but without disturbing or injuring the roots, and give a dressing of pieces of sandstone, from the size of a walnut up to that of the clenched fist, scattering them over the surface, but not so as to cover it completely. Next we would give a scattering of dry bruised bones, equal in quantity to the sandstone, a like quantity of lump charcoal and of mortar from an old building, placing them in the order as named. Upon the charcoal you may give a sprinkling of calcined oyster shells, and upon the lime rubbish place a layer of horse droppings an inch thick, covering the whole to the depth of 6 inches with turves cut 2 inches thick from an old pasture, where the soil is a rather

light loam; the turf cut into pieces about 6 inches square. We would do this now, having first convinced ourselves that the border is well drained, and particularly that there is no stagnant water lodging about the roots at the bottom of the border. A fortnight before applying fire heat, or previous to the Vines commencing growth, cover the border with from 18 inches to 2 feet of hot dung, such as is used for hotbeds, so as to produce a gentle heat. This may remain on until its heat is gone and the weather has become warm, when it may be removed. In the meantime we would prepare the lights with which to cover the border, and we would put them on as soon as the Grapes were ripe, or, if very wet weather, when the Grapes were colouring. Leaving it on all winter you might winter bedding plants under the glass, providing you could keep frost from them; but if they are kept-in late in spring the drip in watering will be injurious to the Vines as the glass covering would in other respects be beneficial. We would not employ it for any such purpose as the growing of Cucumbers or Melons, but, on the contrary, take it away entirely after May, and during that month and April, or even March, in mild weather, remove the lights whenever it rained, so that the border might have the benefit, replacing them after the border had become sufficiently moistened; or, failing rain, the border would require to be watered, especially if the lights were kept on constantly. At the end of May remove them altogether, unless you have particular reasons for keeping them on, as the Grapes ripening, or cold heavy rains occurring about that time, which it will be well to throw off. We would not put them on again until the crop was colouring, and then we would keep them on continuously until we wished the border to become moistened on the Vines again starting into growth. In place of heavy manurings in autumn a top-dressing of turves one-third, horse or sheep droppings one-third, and one-third half-inch bones, charcoal, and calcined oyster shells in equal quantities, would be preferable; a covering 2 inches thick would be ample. Glass-covered borders are good when the covering is movable; but we think them them quite as bad as exposed borders if they are used for plants in winter, and Cucumbers or Melons in summer.

GRAFTING PERESKIA ACULATA (A. B.).—You could not have a better stock on which to graft Epiphyllum truncatum than the Pereskia—indeed, it is the best of stocks. Take off the head of the Pereskia at the required height, and make a slanting cut upwards, and about an inch long, at the top of the stock and on one side. You will cut off a stem or branch from the Epiphyllum to be grafted upon the Pereskia, and pare one side at the lower end in a slanting direction downwards, making it quite thin at the bottom, and so that the cut part shall fit that of the stock exactly. About half way down the slanting cut in the stock make a cut downwards, and about half an inch long, and make a corresponding one upwards in the graft, which will make a sort of slit or tongue in each; that of the graft should be introduced into the one in the stock, and pushed downwards, so that the cut portions of both may fit correctly. The graft may be fastened or bound to the stock with a strip of bast matting, still keeping it in its place and tying tolerably tight, but not very much so. The junction may then be covered with moss, binding it on with matting. It is not necessary to cover with clay. The plant may be placed in a house where there is a gentle heat, and graft and stock alike sprinkled with water twice a day by means of a fine-roset syringe. When the graft begins to grow the matting should be loosened. The best time to graft is in spring, or a little before the Epiphyllum begins to grow. The Ferns sent us were not numbered, so that we cannot refer to them.

GLADIOLUS BULBS (P. I. N.).—We should have preferred to have kept the bulbs on a shelf until they had become dry and parted from their stems, and then have stored them away in dry sand on shelves. The ground where they are to be planted should be well and deeply dug, leaving it rough for the winter, and working in a liberal dressing of manure. The bulbs should be kept out of the reach of frost.

NAMES OF FRUITS (H. A. London).—The Apple from Canada is Pomme grise. (H. H. S.).—No. 1 is Crasanne, a melting Pear when proper, ripened; but in some seasons and in cold situations it does not ripen and then it may be used for stewing. No. 2 is Black Worcester, one of the best stewing Pears. (W. Smith).—1, Beurre Diez; 2, Glout Morceau; 3, Belle de Noel; 4, Huthouse; 5, Winter Pearmain; 6, Crasanne; 7, Marie Louise; 8, No Plus Menris; 11, Beurre Dier from a wall; 12, Vicar of Winkfield. (A. H. G., Faversham).—Your Pear is Beurre de Lance.

NAMES OF PLANTS (J. M.).—We cannot name plants from leaves only.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Nine Days ending December 31st.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE PAST YEAR.

Musing on this subject, we sauntered through some of the London streets on the morning of Christmas-day. It is always

the signal to us to prepare our annual address, and we approach it with mingled feelings. It is seldom cheerful to contemplate the past, and we were at first not gay, but as we walked we became lighter. The streets full of holiday-keepers and pleasure-seekers; the groups of families in full number, starting early for the long enjoyment, to last more than once round the clock; young couples brimful of happiness; the portly

rubicund bachelor uncle, the looked-for of nephews and nieces, with bulging pockets that told of treasures distributed but once in the year; the "irresistible," sporting a sprig of mistletoe in lieu of a flower in his button-hole, and looking at the passing beauties as though challenging them to come and kiss him, just as we have heard of happy countries, illustrated by George Cruikshank, in our early days, where roasted pigs ran about the streets decorated, with knife and fork stuck in their backs, and begging passers-by to eat them; the poor pale woman carrying a baby and leading a small child, and singing carols, cheered by the continuous shower of copper money that fell from those who wished others should be happy as themselves at the happy time. All together seemed cessation of labour on a day that was meant for joy, and all seemed to point to present happiness and future hope. While we reflected that with many the rest, and even the happiness, would be but for a day, still it was real for the time, and we could but think how good it would be if Christmas-day could last till the advent of the new year, and all begin afresh with hearts and feelings enlarged by happiness, and seeking to promote universal peace and joy.

We wished that all who read our weekly sheet might receive it at a happy moment; and we were thankful that in our peaceful career we were not called upon to deal with those questions that produce misery, and generate deadly strife—those things that rank among the great events of nations and men, and that become historical landmarks.

Having to do with none of these, we meet our friends in this our first sheet of the new year with thanks for all kindnesses received during the past. They go far to account for the success that still attends us, and for which we are thankful. Our course is still improving and onwards. Our friends increase in numbers. Giving expression to our true feeling, it is—first, thankfulness that we are spared to address them again; next, gratitude that so many who have supported us during many years remain with us still.

In reviewing the poultry year, we have little to note save an onward and even progress. Much remains to be done before poultry takes the place it should take as a question of food. Our imports of eggs increase yearly, attaining an enormous total; the supplies from France and Belgium are very large. The Ostend Rabbits from the latter country realise sometimes £5000 per week. We are still dependant upon France for most of our Pigeons, and many Turkeys and Geese. They are, however, of an inferior quality to our own. It is a matter of regret that although many hundreds of tons of poultry come from Ireland every year, its low quality, from want of breed, and from bad feeding and packing, makes it of very small value. We have often referred to it in our columns, and have given the necessary instructions to make it sufficiently valuable to double or even treble the returns, but the improvement has not taken place. We do not hesitate to say that the same amount of labour and outlay might easily, being better directed, produce three times the sum it does now.

While speaking of poultry as food, we may well mention the fact that a salesman in Leadenhall Market had this year a consignment of Geese that averaged upwards of 20 lbs. each in weight. Such a fact would have been deemed impossible years ago, and may fairly be put down among the good that has resulted from poultry shows.

Very large prices continue to be realised for table poultry in the spring of the year. Last spring 5s. and 6s. each were common prices for a fowl; they lasted almost from the end of April to the beginning of July. Poultry will never be cheap during that period, but from the 1st of March to the end of June it will always be remunerative. It will pay afterwards, but not at an equal rate. In poultry, as in everything else, he who forestalls the market obtains the highest price. It is the period of scarcity as compared with the natural season of plenty.

Dorkings still supply large classes of almost perfect specimens. If there be any difference the weight increases. New exhibitors have appeared among the prizetakers, running the old ones hard for many of their prizes. These come from all parts of the country, and prove that this valuable breed will do well on all soils, and in any climate. We believe this to be the best of our many breeds. Much regret was felt at the withdrawal of Lady Holmesdale from competition in this and other classes. Her ladyship was deservedly popular. The prices realised at the sale of her stock were very high, and may satisfy her that while she was riding a hobby, she was at the same time doing substantial good by adding to the merit and increasing the value of a breed already highly estimated.

Cochins have held their own well. They deserve to do so, having qualities that may be sought in vain in other breeds. They first solved the question of being able to keep poultry profitably in the small back yard of a densely populated town. Brahmas have increased in numbers, and have maintained a good position among the most important of the classes at our large shows. They, too, deserve all the popularity they enjoy. Game come nearer to perfection than any other breed, and at most exhibitions form a show of their own. This breed seems to have a charm for the English people. We do not wonder at it; none can see without admiring them. The various Hamburgs have, as a whole, been well represented during the year. If there has been a falling-off in any, it has been in the Silver-spangled and pencilled. The love of these breeds seems confined to certain districts, principally the north and north-west of England.

Spanish have decidedly improved, and have taken a step towards returning to what they once were. They have also increased in numbers. We can also note progress in Polands. Silvers have become numerous, and all classes have improved.

We now approach some of our few novelties—the French breeds, Houdans, Crève-Cœurs, La Flèche. The fact of their all being non-sitters will always prevent them from being generally popular in England. We most unhesitatingly give the preference to the Houdan; we place the Crève-Cœur next, and the La Flèche last. The first are never sick nor sorry: they are excellent layers, and easily reared. The second are often sick, but they recover. The hens of the third are tolerably hardy, but the cocks die as fast as they can be imported. They appear to have no constitution. Malays are still where they were; there is no increase of numbers. The Sebright Bantams are becoming less numerous; they want help sadly. Game show by their entries how popular they are. The Blacks and Whites make large classes, and the varieties bid fair to rival their larger brethren. Japan has been placed under contribution. We shall look next year for importations from Abyssinia.

The star of the Aylesbury Ducks pales before that of the Rouen. They are beaten in numbers and weight. The Rouen have mastered the 10 lb. each, which seemed for a long time to be the desideratum of the Aylesbury. The classes for fancy Ducks bid fair to become most attractive and interesting.

Geese are still heavy and make progress, but they seem to have reached their limit. The increase now is made-up of all the birds in the class, rather than in two or three prize-taking pens. This is right, as it shows practical good. Turkeys do not advance much, and we think the American are not shown so numerous or so good as they were formerly.

Poultry shows are still very numerous, but it is certainly true they thrive more in the north than in the south. Entries are well supported, and shows are well attended. The Poultry Club has dissolved itself. It was never needed.

We have no more to say of poultry. We have a few words to say of ourselves. It is seldom a man can speak justly of himself. It is seldom a subject on which a man is eloquent. It is that part which a man would omit. But our task is easy—it is one of returning thanks.

We have told you we are prosperous and prospering. Good and increasingly numerous friends, we thank you for it. We feel in the midst of our labours that we are strengthened, and they are lightened by the thought we have to do only with friends. We have only to repeat our old professions, our earnest desire for the success of the subject of which we treat, our sorrow if one word we have written has caused pain, our disclaimer of any wish to cause it, and our unflinching care, so far as is possible, to be guided *only* by truth and strict impartiality. We meet, then, all our friends in this, the first number of the new year, with hearty thanks for the past. Full of hope for the future, we believe we are wishing them only what they wish us, when we would say to one and all

A HAPPY NEW YEAR.

SEPARATE PRIZES FOR LIGHT AND DARK BRAHMA POOTRAS.

Will you allow me, as one who has stood by the Light Brahmas through good report and evil, to thank Mr. Worthington for his unanswerable letter in your number of December 19th? in which, writing as a breeder and exhibitor of both varieties, he calls upon judges and secretaries of shows to do equal justice to Light and Dark. I well remember, when first

I set up Light Brahmas, being told by a great authority in the poultry world, that they were not the sort to exhibit and win prizes with. Matters have certainly improved since the days when Light and Dark competed together in one class, and when, owing to fashion or fancy, very inferior Dark birds took all the prizes, while the Light ones, however good, were left in the cold shade of at best a high commendation. It was as if horses, cows, and sheep had to compete in one class, and the latter two, however good, had invariably to see all the prizes go to their rivals. If such a state of things were to continue, as in the case of the Brahmas for some time it did, with a horrible monotony, it is obvious that the breeders of the unsuccessful kinds would be discouraged and cease to exhibit, having the certainty of defeat, however good their specimens might be.

Such a fate would have befallen the Light Brahmas had not their friends seen that there was no chance of justice for them under the existing state of things, and consequently exerted themselves to obtain that justice in the shape of a separate class. This is now allotted to them at all the leading and most of the second-rate shows. But alas! there is still a vestige of the old intolerance left, only befitting the days when Light Brahmas at an exhibition were like angels' visits, "few and far between;" utterly unsuited to the present time, when any respectable show can boast its flourishing class of those once-rare beauties.

Mr. Worthington most truly points out that in cases where a cup is given to be competed for by Light and Dark it is invariably given to the latter.

I can confirm Mr. Worthington's statement by a case in point. I once had a Light Brahma cock, the like of which, and I speak with the experience of some years, I do not ever expect to see again! He was never beaten by any bird of his own breed, and prize after prize, awarded by the first judges, attested his merits. One of these gentlemen told me subsequently that this bird was a "model of what a Light Brahma should be; that since his death he had seen none to equal him, and that when taken out of his pen and compared with Dark birds he dwarfed them by comparison." A second judge declared "that he was the best Light Brahma cock he had ever seen." Now this bird, although competing often against Darks for a cup, never was successful!

Among your numerous readers there must be many secretaries and managers of shows. Let them take a hint from Mr. Worthington's letter, and instead of offering a cup or other special prize between Light and Dark Brahmas, let them give an extra prize or cup (less in value though it be), in each class. By so doing they will add, not merely to the satisfaction of exhibitors, but to the convenience of the judges; in witness whereof let me appeal to a complaint lately made in this Journal, by some one writing from the judges' point of view, of the difficulty and invidious nature of the task imposed upon a judge who has to award a special prize which is competed for by several varieties. In cases where Mr. Worthington's suggestion is not followed out, and the plan adopted of giving separate prizes or cups, instead of one cup competed for by different breeds, there is still a remedy left for the injustice of which Mr. Worthington complains.

Let it not be assumed as a matter of course that the Darks are more popular, and should therefore have the cup. This may have been very well once, when there were not, as now, well-filled classes of their rivals. Besides, "to go with the multitude" is not always the best! Still less should private preference come into the question. Nor, again, should it be said, "the Darks are the biggest," which is often not the case; and if it were so, by no means decisive.

All these are wrong methods of arriving at a decision. And here we come to the gist of the whole matter. The cup should be given, not to the best comparatively of the two breeds, but to the best relatively of its own variety. The Dark bird does not deserve the cup unless he is better as a Dark bird than the Light bird is as a Light one. The point to guide the judge should be the comparison of the bird with the standard of his own breed, and not of the other.

To make the matter more clear, take the case of a cup to be given to the best pen of Geese or Ducks at a show. If the Geese won, it ought to be, not because the judge thought they looked larger kinds, or because he liked Geese better, but because the Geese, as compared with other Geese, were better than the Ducks, compared with other Ducks. And as in the above instance it would be quite possible for the Ducks to win the cup, so ought the Light Brahmas, if better of their own sort, to win the cup also. From a neglect of this

principle, mistakes have arisen; when it is followed justice is done.

What Mr. Worthington calls for, and what the Light Brahma breeders want, is simple justice to the Light birds, not that they should be preferred above Dark birds when less deserving, but that they should not be tantalised with the seeming offer of prizes they cannot possibly win, and be beaten by specimens of another breed relatively less good, simply on the ground of the latter being Dark!—JOHN PARES, *Postford near Guildford*.

I AM very glad to see, in "our Journal" of December 19th, that Mr. Worthington has spoken a word for the Light Brahmas in exhibitions when competing with Dark. It does seem very unfair that they should have no chance of winning a cup, even against Dark Brahmas, which are inferior of their class. Surely both should stand an equal chance. Mr. Worthington's suggestion, that a cup should be given to each variety, seems a very good one, and one that would overcome the difficulty.

At the Guildford Show the Light birds did for once triumph over the Dark, Mr. Pares taking first, second, and extra prize, and a high commendation; while only one pen of Dark was highly commended, but the rest of the Dark were very inferior.—PHILIP CROWLEY.

JUDGING POULTRY—PRIZES OFFERED ERRONEOUSLY.

WOULD not many errors and much fault-finding be prevented by having a third Judge? The one would not then have to give way to the other in any opinion he may have formed on a particular pen of birds, the majority, two to one, carrying the award. I think the plan of having a third Judge would in a great measure do away with the grumbling and fault-finding by disappointed exhibitors.

I greatly admire your remarks on the Guildford Show, especially in reference to the awarding a cup for the best pen in the Show. This cup must always cause a large amount of jealousy to the winners of first prizes, each, of course, thinking his or her pen the best, and as best, of course in their idea entitled to the extra cup. This prize must often puzzle the Judges.

I would also do away with the cup for the best cock or cockerel in the show. Let the exhibitor of each single bird be satisfied (when he wins it), with a first prize; increase the amount of such prize if you like, and if the funds will allow it, but do not offer the extra cup, as it causes much ill feeling. In giving the cup for Bantams, I would also name the class that it is to be awarded to, and not offer it for general competition to any class of Bantams. At Bristol, a seven-guinea cup was offered for the best pen of Bantams, which caused no less than sixty-six entries of Game alone; some, I hear, costing fifteen guineas a-pen, bought purposely to win this cup. What was the result? a solitary entry of Pekins swept away the cup from the sixty-six pens of Game, the fifteen-guinea pens included. There would have been more satisfaction if the cup had been offered to Game Bantams alone, as this variety evidently pays best. At Leeds Black Bantams took the cup, the same also occurring at Newport.—G. T.

HECKMONDWIKE POULTRY SHOW.

AT no previous meeting has there been so large an entry; nor, as a whole, such a good competition as at that held on the 26th of December. This Show has always been very popular, and it appears to be the meeting of the year at which the breeders in the district contend for the premiership more than for the value of the prizes offered.

Game fowls were first on the list, and every class contained splendid birds. The first-prize Game fowls were equal to any seen at our large shows. Game Bantams as usual formed large classes, and the prizes were awarded to birds of the real Game colour and style. Black Bantams are always good at this Show. Spanish and Hamburgs were very good also. The Single Game hen class contained many first-class birds, the prize hen being one of the best Brown Reds we have seen for some time.

There was a good show of Pigeons, and the prize birds were very much admired.

The Exhibition was held in a large and well-lighted room, no person was allowed to enter until the Judge had completed his task, which we know gave every satisfaction.

GAME (Black-breasted).—First, G. Noble, Staincliffe. Second, C. Smithson, Heckmondwike.

GAME (Brown Red).—First, T. Suddick, Bradford. Second, H. Hutton, Cleckheaton.

GAME (Duckwings and other Greys and Blue).—First, B. Naylor, Heckmondwike. Second, W. Fell, Adwalton.

GAME (Any other variety).—First, W. Turner, Drighlington (Piles) Second, J. Brook, Gomersal (Black).

GAME BANTAMS (Red).—First, G. Noble. Second, C. Clegg, Heckmondwike.

GAME BANTAMS (Duckwing).—First, J. Hirst, Heckmondwike. Second, I. Goodall, Heckmondwike.

BANTAMS (Any other variety).—First, J. Parker, Heckmondwike. Second, S. Schofield, Heckmondwike.

SPANISH (Black).—First, S. Newsome, Heckmondwike. Second, J. Brooke, Gomersal.

HAMEBURNS (Any colour).—First, T. Swires, Cleckheaton (Golden-pencilled). Second, J. F. Loversedge, Newark, Notts (Gold-spangled).

COCHIN-CHINA (Any colour).—First, S. Schofield.

ANY OTHER VARIETY.—First, H. Firth, Bradford (Silver Poland). Second, A. Farrer, Staincliffe (Brahmas).

GAME HEN (Any colour).—First, T. Siddick. Second, W. Fell.

SELLING CLASS.—First, W. Walker, Gomersal (Piles). Second, S. Schofield.

PIGEONS.

CARRIERS.—Prize, J. Firth, jun., Dewsbury.

ANTWERPS.—Prize, A. Wilman, Dewsbury Moor.

TUMBLERS.—First, R. France, Heckmondwike. Second, H. Firth, Bradford.

OWLS.—First, H. Firth. Second, J. W. Horsfall, Dewsbury.

COMMON.—Prize, H. Firth.

DRAGONS.—First, J. Nutter, Cleckheaton. Second, R. France.

ANY OTHER VARIETY.—First and Second, J. Firth, jun. (Black Barbs and Black Trumpeters).

JUDGE.—Mr. John Crosland, jun., Wakefield.

NORTH OF ENGLAND ORNITHOLOGICAL ASSOCIATION'S SHOW.

This Exhibition of British and Foreign Cage and Song Birds was held in the New Infirmary, Sunderland, on December 26th, 27th, and 28th. This Show was very successful, and pronounced by Judges the "best" ever seen in England for quality. The subdivision of the Norwich classes was highly approved, and the successful birds were very superior. The stock shown by Mr. Orme and Mr. Walter was admirable. Mr. Rutter's Belgians were something marvellous. Of Mules there was a very large entry, and of very superior quality. The specimens sent by Mr. Ashton and Mr. Tully were remarkably fine. The Show was opened by Earl Vane.

Mr. Ashton won prizes amounting to £5, and a £5 cup; Mr. Rutter won the Committee's Cup.

We cannot too strongly applaud nor too pointedly draw attention to the Society's attempt to develop the Norwich classes—they have achieved a success; and the Society deserves, and we hope in future will obtain, more support from Norwich.

CANARIES.

NORWICH (Clear Yellow).—First, E. Orme, High Street, Derby. Second and Very Highly Commended, W. Walter, Winchester. Third, Highly Commended, and Commended, J. Bexson, Derby.

NORWICH (Clear Buff).—First, Second, Third, and Highly Commended, E. Orme. Very Highly Commended, W. Walter. Commended, J. Bexson.

NORWICH (Variegated Yellow).—First, H. Ashton, Prestwich, near Manchester. Second, G. Parkinson, Houghton-le-Spring, Durham. Third, J. Baxter, Newcastle. Very Highly Commended, E. Orme. Highly Commended, J. Stainsby, Sunderland. Commended, G. Moore, Northampton.

NORWICH (Variegated Buff).—First and Second, E. Orme. Third, S. Tomes, Northampton. Very Highly Commended and Highly Commended, J. Bexson. Commended, W. Walter.

NORWICH (Marked Yellow).—First, W. Walter. Second and Very Highly Commended, E. Orme. Third and Commended, J. Bexson. Highly Commended, G. Moore.

NORWICH (Marked Buff).—First, Third, and Very Highly Commended, E. Orme. Second and Highly Commended, J. Bexson. Commended, W. Walter.

NORWICH (Yellow, with Green, Grey, or Yellow Crest).—First and Third, W. Walter. Second, J. Wilkinson, Numbers Garth, Sunderland. Very Highly Commended, S. Tomes. Highly Commended and Commended, J. Rutter, Bishopwearmouth.

NORWICH (Buff, with Green, Grey, or Buff Crest).—First, J. Tully, Monkwearmouth. Second, G. Moore. Third, J. Stainsby. Very Highly Commended and Commended, W. Walter. Highly Commended, H. Ashton.

NORWICH (Variegated-crested Yellow).—First, H. Ashton. Second and Very Highly Commended, G. Moore. Third, J. Gibson, Ryhope. Highly Commended, W. Walter. Commended, G. Shiel, Bishopwearmouth.

NORWICH (Variegated-crested Buff).—First, J. Gibson. Second, G. Moore. Third and Very Highly Commended, W. Walter. Highly Commended, G. Shiel. Commended, J. Gibson.

NORWICH (Marked-crested Yellow).—First, W. Walter. Second, F. W. Fairbrass, Canterbury. Third, J. Bexson. Very Highly Commended, J. Stainsby. Highly Commended and Commended, G. Moore.

NORWICH (Marked-crested Buff).—First and Very Highly Commended, W. Walter. Second, T. Reid, West Sannside, Sunderland. Third and Commended, G. Moore. Highly Commended, G. Shiel.

NORWICH (Any variety).—First, G. Moore. Second, G. Shiel. Third, J. Tully. Very Highly Commended, J. Bexson. Highly Commended, W. Walter.

BELGIAN (Clear Yellow).—First and Second, J. Rutter. Third, E. Orme. Very Highly Commended and Highly Commended, W. Bulmer, jun., Stockton. Commended, W. Inson, Redland, Bristol.

BELGIAN (Clear Buff).—First, Highly Commended, and Commended, J. Rutter. Second, E. Orme. Third, H. Ashton. Very Highly Commended, W. Bulmer, jun.

BELGIAN (Marked Yellow).—First and Second, J. Rutter. Third, W. Bulmer, jun. Very Highly Commended, H. Ashton. Highly Commended, W. Inson.

BELGIAN (Marked Buff).—First, Second, Third, and Very Highly Commended, J. Rutter. Highly Commended, H. Ashton. Commended, E. Baker, Parkham, Gateshead.

BELGIAN (Variegated Yellow).—First, Second, and Very Highly Commended, J. Rutter. Third, W. Inson.

BELGIAN (Variegated Buff).—First, W. Bulmer, jun. Second, J. Rutter. Third, J. Wilkinson. Very Highly Commended, W. Richards, Bulwell, Nottingham.

GLASGOW DON (Clear).—First and Third, J. Forsyth, Elswick, East Jarrow, Newcastle. Second and Very Highly Commended, G. Nicholson. Highly Commended, W. Young, Belford. Commended, J. Greenlees, Sunderland.

GLASGOW DON (Variegated or Marked).—First, Second, Third, and Very Highly Commended, G. Park, Galashiels. Commended, J. Greenlees; W. Walter.

YELLOW CINNAMON.—First, W. Walter. Second, S. Tomes. Third, Very Highly Commended, and Highly Commended, G. Moore. Commended, E. Mills, Sunderland.

BUFF CINNAMON.—First, S. Tomes. Second and Third, G. Moore. Very Highly Commended, W. W. Yeld, Bishopwearmouth. Highly Commended, J. Bexson. Commended, E. Orme.

YELLOW CINNAMON (Variegated or Marked).—First, W. Rogers, Sunderland. Third, E. Orme. Third, J. Tully. Very Highly Commended, S. Tomes. Highly Commended, J. Galley, Newbottle, near Sunderland. Commended, G. Moore.

BUFF CINNAMON (Variegated or Marked).—First, J. Baxter. Second, W. Rogers. Third, T. Tully. Very Highly Commended, G. Moore. Highly Commended, H. Ashton. Commended, J. Oxberry, Bishopwearmouth.

LIZARD (Golden-spangled).—First, H. Ashton. Second and Highly Commended, E. Orme. Third, J. Rutter. Very Highly Commended, J. Tully. Commended, Rev. V. Ward, Canterbury.

LIZARD (Silver-spangled).—First and Highly Commended, E. Orme. Second, J. Tully. Third, H. Ashton. Very Highly Commended, T. Fairbrass, Canterbury. Commended, E. W. Fairbrass, Canterbury.

LONDON FANCY (Yellow).—First and Third, T. Mano, Camberwell New Road, London. Second, H. Ashton.

LONDON FANCY (Buff).—First, H. Ashton. Second, and Third, T. Mano.

CANARY (Green).—First, G. Atkinson, Gateshead. Second, M. Stelling, Brancepeth Colliery, Durham. Third, J. Wilkinson. Very Highly Commended, R. Robinson, Middlesbrough. Commended, J. Wilkinson.

CANARY (Any other variety).—First and Very Highly Commended, H. Ashton (Crested Belgian). Second, R. Hawman, Middlesbrough (Common Variegated). Third, T. Walter (Yorkshire). Highly Commended and Commended, W. Heap, Bradford (Yorkshire).

CAGE OF CANARIES AND MULES.—First, W. Walter. Second, J. Tully, Third, H. Ashton.

GOLDFINCH MULE (Variegated Yellow).—First and Third, H. Ashton. Second, J. Tully. Very Highly Commended, T. E. Colman, Clapham Common. Highly Commended, R. Robinson, Middlesbrough. Commended, J. Bexson.

GOLDFINCH MULE (Variegated Buff).—First and Third, H. Ashton. Second, E. Orme. Very Highly Commended, G. Parkinson. Highly Commended and Commended, G. Moore.

GOLDFINCH MULE (Marked Yellow).—First and Commended, H. Ashton. Second, W. Heap. Third and Highly Commended, G. Shiel. Very Highly Commended, J. Tully.

GOLDFINCH MULE (Marked Buff).—First and Third, J. Tully. Second, E. Orme. Very Highly Commended and Highly Commended, G. Parkinson. Commended, W. Heap.

MULE (Dark).—First, J. Tully. Second, W. Rogers. Third, W. Walter. Very Highly Commended, M. Stelling. Highly Commended, W. Heap. Commended, W. Yeoman.

LINNET MULE.—First, T. Peat. Second and Third, H. Ashton. Very Highly Commended, T. E. Coleman. Highly Commended, J. Tully. Commended, W. Walter.

MULE (Any other variety).—First and Highly Commended, W. Walter (Bullfinch and Goldfinch). Second, T. E. Colman (Bullfinch and Goldfinch). Third, Very Highly Commended, and Commended, H. Ashton (Bullfinch, Goldfinch, Greenfinch, Goldfinch, Chaffinch and Brambling).

BULLFINCH.—Prize, W. Walter.

GOLDFINCH.—Prize, W. Walter. Highly Commended, M. Stelling.

LINNET.—Prize, M. Stelling.

SKYLARK.—Prize, J. Gibson.

BLACKBIRD.—Prize, W. Mano.

SONG THRUSH.—First, J. Gibson. Second, W. Wrightson.

STARLING.—Prize, M. Stelling. Very Highly Commended, W. Walter.

ANY OTHER VARIETY OF BRITISH BIRDS.—Prize, H. P. Yeld, Sunderland (Chaffinch).

PARROT (Any variety).—First, H. Ashton (Red-breasted Australian). Second, G. Robinson, Durham (African Grey).

LOVE BIRDS.—Prize, W. Walter.

PARAKEET (Any variety).—First, H. Ashton (Grass Parakeets). Second, W. Walter (Grass Parakeets).

ANY OTHER VARIETY OF FOREIGN BIRDS.—First, W. Walter (Nonpareil). Second, T. Reid (Saffron Finch).

The Judges were Mr. T. Allenby, Durham; Mr. T. Clark, Sunderland; Mr. G. J. Barnesby, Derby.

HEDGEHOGS AND BLACKBEETLES.

I can confirm, Messrs. Editors, all that Mr. Frank Buckland observes in *Land and Water*, as to the little effect produced by a hedgehog in the destruction of beetles. He tells us very amusingly:—

"I have tried hedgehogs to kill beetles; they don't act. A hedgehog cannot possibly hold above a pint of beetles at a time,

and in my kitchen there are gallons of them. I once tried the hedgehog plan at the Deanery, Westminster. The first night after his arrival the Abbey watchman was frightened out of his wits—it was the hedgehog. The next night, fast asleep, I felt a cold nose on my face, and then a prickly thing trying to get into the bed—it was the hedgehog. The next night the servant came trembling to say there was a burglar in the dining-room, rattling the plate—it was the hedgehog. The next night the cook put some soup away, and in the morning the soup was gone—the hedgehog was found coiled up asleep in the tureen. The next night nothing was heard of the hedgehog, and for weeks we could not tell where he was gone; the cook was thankful, and the crickets sang, O, be joyful, while the blackbeetles had the free run of the kitchen. 'Years rolled on,' as the novelists have it, and a skeleton was discovered in the flue, which had smoked the whole of the house out for weeks. The hedgehog again. Thank goodness, I have seen the last of that wretch, and never wish to have another of his kind on the premises. Unless, therefore, my friends wish to run the chance of a hedgehog becoming the same pest to them as he was to me, they will never introduce them into their houses. Hedgehogs will only eat a certain number of beetles, and the beetles having good spawning ground behind the kitchen range, breed much faster than the hedgehog can eat."

I have, however, found that by the use of some phosphoric boluses prepared by Mr. Chase, of 14, Holborn, the beetles are destroyed very effectually. It is well, however, to give the beetles a supper of these at intervals of a fortnight, so that the successional crops of the young blacks may be also provided for.—C. W. J.

FOUL BROOD—LIGURIAN QUEEN RAISING.

THE majority of the readers of the bee department of "our Journal" are aware that the breeding of artificial queens, increase of stocks, and their welfare, are in proportion to the abundance and length of the honey season. The absence of the former, and short duration of the latter, limited the harvest of honey from my stock hives, yet has not prevented my raising a fair quantity of queens from the stock of Ligurians received from Mr. Woodbury last April, and also a few from the foul-breeding one obtained from Messrs. Neighbour & Sons, who, I may here say, have since made me full compensation for that unfortunate occurrence.

About the middle of May I commenced the interesting experiment of making artificial swarms, as recommended and described in this Journal by Mr. Woodbury. From the above date to the 2nd of July I had made sufficient swarms to enable me to raise twelve Ligurian queens, which were all out by the 12th of July. I had still another Ligurian queen, raised naturally; for the original stock, after all my manipulations and the abstraction of five ripe brood combs for artificial swarms, and the bees, to strengthen them, threw off a swarm on the 14th of July, the weight of which was a little more than 6 lbs! When looking over the original stock some days afterwards I discovered unmistakable signs of foul brood in a frame that had come from a stock, the combs of which had been exchanged with those of Messrs. Neighbours' diseased one before I was aware of the existence of that terrible malady. The original Ligurian was the only stock I saw attempt to clean out foul cells, which it did most thoroughly.

The last queen made thirteen queens, nine of which were from Mr. Woodbury's stock, and four from Messrs. Neighbours'. Eleven of these became impregnated, and seven of them bred pure Ligurians. This I consider a good percentage of pure-breeding queens, considering that I had only three stocks that bred pure drones. I still have five of those pure queens, which were given to black and hybridised bees, as I shall presently show. The rest I gave away or destroyed, with their bees, at the break-up of my old apiary from foul brood, which caused the destruction of sixteen stocks and nuclei, as well as the loss of 120 frames of straight worker brood combs!

Before giving an account of how I succeeded in adding these queens to populous stocks and driven bees, I may be permitted to state the cause of these proceedings, which was this. When I had increased my apiary to upwards of twenty stocks, I made the unpleasant discovery of the existence of foul brood (as described in the Journal of the 1st of August last) in all my nuclei and first-formed stocks; the black bees set apart to strengthen swarms, and all, were eventually infected by it, with the exception of three supered stocks, two of which were black bees and the third hybrids.

My first step was, on the 11th of July, to put the diseased stock through quarantine,* but I left matters generally much as they were until my neighbours began to take their bees. Such being the case, on the 7th of August I commenced operations by driving the bees of two condemned stocks separately, conveyed them home—a mile distant—taking from them at once their queens, and putting them together in an empty straw skep. Twenty-four to thirty hours afterwards I offered them the last-mentioned queen in the manner described by "J. R. J.," in No. 337, on the top of the hive under a wine glass, letting in the bees one or two at a time to see how they received their future sovereign. They at once took to her, so I transferred them to a full-sized Woodbury hive with six frames of brood from other condemned colonies. They were fed liberally, and are now one of my stock hives.

My second essay was as follows:—I drove two other stocks of bees at once, and brought them to my trial ground, as I now styled the old orchard, which is upwards of 100 yards distant from the apiary. Being deprived of their queen as before, they were also left twenty-four to thirty hours. I then drove all the bees out of the two Stewarton boxes, taking them to the poor unfortunates, knocking the latter out on a sheet, and setting the heavy Stewarton boxes in front of them. They very soon began a march towards them; and as they entered them with the song of gladness, I presented them with a young fertile Ligurian queen, which was welcomed with excessive joy, as they marched merrily into their well-furnished dwelling.

The next attempt was with a stock of bees in a frame hive that had swarmed twice, and had one of those small queens which I have mentioned before. She was removed, and another fertile Ligurian presented to them the same day, towards evening, on the top of the hive. All went well with this stock, for the next day they began to carry in pollen, and killed-off their drones.

In the same manner I continued my exchange of queens, the driven bees of one stock that was healthy being ready for the next. Simultaneously with the removal of the Ligurian queens from diseased stocks, I destroyed them, and so continued until I had disposed of them all, principally introducing them at the top of the hive. At times I had a rebel to deal with; but I was in the end successful with the whole six.

In the case of the seventh essay, both the theory and practice of giving queens at the top, as described by "J. R. J.," and which he seemed confident was never-failing, was thrown to the winds.

Two other lots of driven bees were each early one morning deprived of their queens. They even were so good-natured as to unite of their own accord. About thirty hours afterwards my favourite queen was offered to them, precisely the same precautions being taken, the same means used, and all visible conditions being precisely identical. But, no, they would not have her. One bee would fight, and a number soon clung round her like a ball, which I separated, bee by bee, in my naked hands without receiving a sting, until I came to the unfortunate queen. They did not seem to try to sting her, but only held her fast. After being rescued from them she was placed over the hive until the fourth day, when matters appearing a little more peaceable she was let in, but on the eighth day was turned out dead, proving that in bee life there is no rule without its exceptions.

The instincts of the bees are, no doubt, sufficient for them in their native regions, and in their wild state. Here they are, as it were, under foreign conditions—driven from their stores, deprived of their queen; and under such circumstances we must not be surprised if we do not always find results in accordance with our expectations. Further, if we could know all the unseen causes that are at work, I believe we should then find that they always do precisely the same thing under the same conditions. Apparent are not always real circumstances. Apart from the accepting of queens, there is at times the refusal of combs, the refusal of hives, and many other apparent anomalies, all of which have their cause.

Lastly, as regards the best method of giving bees new queens, with all due deference to Mr. Woodbury's plan which is, no doubt, the best for his hives, let me ask how he would carry it out in Stewarton boxes, without frames, and in common straw hives. It is not my intention to offer any opinion of my own, not, but that it is decided enough. In conclusion, then, I must apologise for having taken up so much valuable space in

* I eventually destroyed it, keeping its queen for future use.

describing how I succeeded, and where I failed in my manipulations.—J. B., *Bracken Hill*.

[I may be permitted to remind my friend, that I stated at the time that the mode of adding Ligurian queens, which I described as being the best with which I am acquainted, was adapted only to moveable comb hives. For hives with fixed combs, his mode of operating is probably as good as any that can be devised.—A DEVONSHIRE BEE-KEEPER.]

SILKWORM-REARING IN ENGLAND.—No. 4.

Japanese Silkworms.—I must more especially notice these worms, which have been introduced into Europe during the last few years, and are becoming much cultivated on account of their exemption from the "atrofia" so prevalent in other breeds. These are small worms of four sleeps, or changes of skin, and produce yellow, white, green, or sulphur-coloured silk. There is what is called the annual kind, which produces only one crop. This is the most esteemed. Then there are the "Bivoltini and "Trevoltini," sorts producing two and three crops, but which are not much sought after in consequence of their produce being uncertain in very hot weather, and the difficulty of always having sufficient leaves to feed them: for it is injurious, nay, impossible, to gather the leaves twice without spoiling the mulberry trees; indeed, in England these should never be wholly stripped.

On leaving Piedmont in August, 1867, I brought to England with me eggs of the Trevoltini which were hatching on my arrival in London, they being the third succession of eggs. On reaching home I fed and reared the worms quite successfully. The cocoons were spun in October, and fresh eggs deposited by the moths in November. I think, if for rearing in England, that the second crop would be the most useful, as it would be produced in the hottest of the weather here, the first crop being limited to the mere production of eggs, and in this way the mulberry leaves would remain on the trees to grow large before being used. I am not recommending the use of these silkworms rather than the annual kinds, but there are circumstances in which they might be useful, especially in this climate. The eggs of the annual breeds are to be kept, by proper management, so as not to hatch too early in the spring, or until the mulberry leaves are well advanced in growth.

I once laid a nearly full-grown silkworm on a young gentleman's hand, to look at. He started with fright on feeling its coldness, and innocently said, "Oh, dear! how cold you keep your silkworms!" He did not know that silkworms are cold-blooded. Many persons do not know it. The heat of the silkworm's yellowish blood is about equal to that of the air in which it lives. The greater the temperature the quicker the functions of the worms, and therefore the faster the food is consumed and the silk produced. Cold, on the other hand, retards the functions, and consequently the final result.

When silkworms are within a day or so of their sleep, their appetite considerably diminishes, which may be readily observed by their not consuming the leaves so much as at other times. During their sleep they eat nothing. After the sleep and change of skin, which occupy two days, more or less, they again begin to eat, although sparingly at first, but in a couple of days they will be in full appetite. At each meal one may readily judge what quantity of leaves to distribute over them by the more or less rapid consumption.

Just before their sleep they spin over the leaves, or other objects on the tables or stages on which they are, a fine web, hardly perceptible to the naked eye, over which they firmly station themselves, and thus their old skins are held while they walk out, leaving them behind. Wherever worms station themselves to undergo this operation, they must not be touched or moved, but remain under what fresh leaves are given to those not yet ready to sleep, for it rarely happens that all will do so the same day. The insect, during the sleep, keeps the head upwards, remaining fixed like a statue, and showing no sign of life unless interfered with. Immediately after the change of skin it is weak, and remains a short time while gaining strength before again eating. At the moment the change of skin is going on, there may be seen a certain lumour exuding from the insect's body, between the old and new skin, which doubtless facilitates the shifting of the then useless and burdensome skin.

The four changes of skin to which the insect is subject occur at intervals of from six to eight days. After each of the first three changes it increases in size to about double, but after the

fourth change it becomes several times larger, growing rapidly during the period of ten days or so before spinning.

When the worm has arrived at its full size it ceases to eat, and voids all excrements, becomes crisp about the skin above the head, and transparent in the body. It then goes about in search of a suitable place to produce the cone of silk. Materials for the purpose must be supplied. It is usual on the Continent to form a kind of hedge for the worms to work in, by tying together branches in broom fashion with open heads, and placing them upright on the worms' stages.

The silkworm's life is divisible into seven periods, or "seven ages"—viz., the period from the time of hatching to the first sleep, from that to the second sleep, from the second to the third sleep, from the third to the fourth, from the fourth sleep to the spinning, from beginning to spin to the conversion into the chrysalis, and the change from the chrysalis to the moth or perfect state. The time occupied by the worm in spinning is variously estimated at from four to six days; but the chrysalis is generally perfectly formed on the eighth day, and the moth may be expected out of the cocoon in about fourteen days more. These transformations depend, however, on the influence of more or less heat.

The degree of heat most suitable in a silkworm-rearing room is 70° Fah.; I mean when artificial heat is employed, as it must be; but when the natural temperature is more, say even above 80°, it will not be injurious to the worms, provided plenty of air be admitted to the room. I fix 70°, little over or under, as the most beneficial for the worms during their entire life. Sudden variations of temperature are hurtful, and much of the success of silkworm-rearing is to be ascribed to the correct regulation of the temperature, to the supply of the leaves, to proper ventilation, and to cleanliness.

A colder temperature is not really hurtful, but only retards the worms' development, unless when they are about spinning, in which case cold hardens the silky matter contained in their bodies, and they then cannot emit the silk. A suffocating heat is in general much more injurious than cold to a certain extent. A stagnant humid atmosphere is more prejudicial, especially when accompanied by too much heat. Dry weather is favourable to the worms, and for gathering the leaves, which should not be used in a wet state. Smoke will suffocate the worms, and bad rooms must be guarded against, as also mice, pigeons, and chickens, which will eat them with relish if allowed. Flies are also tormenting, and should be removed from the room or caught by some means. Light exercises a beneficial influence on the insect, and at night a proper illumination is beneficial.

Care must be taken to avoid in the silkworm room putridity, which may arise from various causes, such as neglect of cleanliness, by allowing the excrements and waste leaves to accumulate on the stages where the worms are.

Various experiments have been made to test the degree of cold silkworms' eggs and silkworms themselves will endure without destruction. The eggs have been exposed to severe frost in alpine districts without the least injury. The worms have been laid on ice for several minutes, and have survived the shock. They may be immersed in water, and even when apparently dead will revive, if not left too long therein. Tobacco smoke and snuff will kill them, and death occurs instantly if their eighteen breathing holes be stopped.

Having said thus much by way of introduction, I think it time to come to the more practical part, by noticing such instruments and other articles as are necessary in rearing silkworms.—LEONARD HARMAN, JUN.

OUR LETTER BOX.

POULTRY JUDGES (*A Subscriber*).—It is sufficiently difficult already to find well-qualified judges without our rendering it still more difficult by casting suspicions on their decisions. If, as you suggest, "one hundred first-rate judges" could be named, from whom a choice might be made, there would be no difficulty. We agree with you that judges should not be residents near the Show; but we otherwise differ from you.

BOOK (*W. H. H.*).—"The Pigeon Book," by B. P. Brent. You can have it free by post from our office if you forward twenty postage stamps with your address.

AQUARIUM MAKING (*An Inquirer*).—We know of no work that we can recommend.

ISLAND OF PERU.—"I notice that a constant advertiser in the *Journal* speaks of White Peruvian Musk Ducks as "imported from the island of Peru." It is some years since I went to school, and I have forgotten my geography. Where is the place?—T. C. II."

DARK BRAHMA COCK (*Fairplay*).—It may have been a prizetaker last year. You had better write to the advertiser for particulars.

From observations taken near London during the last forty-one years, the average day temperature of the week is 41.0°; and its night temperature 30.1°. The greatest heat was 54°, on the 9th, 1862; and 12th, 1852; and the lowest cold 4°, on the 14th, 1838. The greatest fall of rain was 0.86 inch.

HINTS FOR AMATEURS.

IN these days of cheap glass and patent houses which may be packed-up with other goods and chattels on a tenant's removal, it has become quite the rule to see at least one glass house in the grounds of most suburban villas and other places of a similar character, in which that enthusiastic individual the amateur may display his gardening ability, and pass many an hour of healthy recreation and enjoyment. I believe I am correct in the conclusion that this enjoyment will be felt in proportion to the amount of practical knowledge possessed, and therefore, a few remarks on this subject may not be unwelcome.

One of the first and most important considerations to be kept in view is economy, not only of money but of space, so as to find room for the cultivation of as many varieties of plants as possible, and thus afford a greater amount of gratification; not that I am at all an advocate for that system of which amateurs have so frequently been accused—namely, of attempting to grow everything, and succeeding with nothing, but because, judging from many instances which have come under my notice, I am certain that many owners of a glass house do not derive that gratification from its possession which it is fairly calculated to afford. Of course, if the house is designed for the growth of any particular class of plants, that is a different affair, and has nothing to do with the kind of general-purposes house of which I purpose treating.

I will suppose a house of this kind to be a lean-to, having a stage in the body of the house, and a shelf or stage near the front sashes, and over the pipes or flue, with other shelves near the glass. Doubtless in winter the greater portion of the space will be occupied by bedding plants, and the remainder by a few greenhouse plants.

Of these, one of the best for winter flowering is the *Primula*, which may be had in bloom all the winter by following the excellent cultural directions given in No. 351. After the plants have received their final shift, and have a sufficient number of strong leaves, these should be drawn gently down to the edge of the pot by bast connected with a wire under the rim; other leaves in abundance spring up, and fill the central space; more of these are brought down to meet the others as may be required until a compact mass of leaves is formed, out of which the blossoms spring, interspersed with a few fresh young leaves. This training is not requisite in every case, as some varieties are naturally of a spreading habit.

Cinerarias are also most useful for winter and spring blooming; also a few *Camellias*, *Azaleas*, winter-flowering *Ericas*, *Epacris*, *Carnations*, and *Mignonette*, the last sown in March, and grown either as dwarf bushes or trained to pyramids, which form is, I think, the most graceful of all for this plant.

Of *Cyclamen persicum*, young seedlings will produce thirty or forty blooms in the first year, if the seed is sown in March in heat, and the young plants put first into thumb pots, and kept in the same heat till somewhat

established, when they are taken to a cool house, and shifted into large 60's, in which pots they blossom early in the autumn if kept in the house all the summer. This is a most desirable plant, continuing in bloom during the winter and the early part of spring.

Solanum capsicastrum, with its bright red berries and deep green foliage, is a most useful and charming plant for winter decoration. Young plants turned out of the pots in May, and planted in any warm border in common garden soil, form pretty plants by the autumn, making a dense growth, and being loaded with green berries which become scarlet by Christmas. The plants may be taken up early in October, and potted, retaining a slight ball of earth; they are placed in a shaded part of the house and syringed twice or thrice a-day until they are established.

This list might be extended considerably, but I think the plants named are well calculated to afford a pleasing and sufficient variety of blossom in the duller months of the year, and are also all of most easy culture. To follow these there may be a few herbaceous *Calceolarias* sown in June, shifted into larger pots as necessary during the winter, and kept on a shelf near the glass; *Pelargoniums*, and, above all for a summer display, some *Fuchsias*, which may be wintered under the stage.

The removal of the bedding plants to the open air should be followed by the introduction of a row of pot Vines along the front stage, one to each rafter. Now, supposing the rafter to be 12 feet in length, the pot Vines will not require more than half of its length; the remainder, or top part of the roof, may very profitably be turned to account by placing on the back stage under each rafter a large pot to be three-parts filled with rich loamy soil, with plenty of drainage, and a Cucumber plant to be turned out into each pot. It will add very much to the grower's pleasure if a different variety be put in each pot, and much useful and interesting information may be gained in this way.

During the past summer I grew in pots a plant of each of the following sorts:—*Kirklees Hall Defiance*, *Dr. Livingstone*, *Empress Eugénie*, *Paul's Telegraph*, and *Hedder Winter Prolific*. Of these, *Telegraph* showed fruit first, and *Empress Eugénie* last. *Dr. Livingstone* was the most prolific, having as many as twelve fruit at one time all fit to eat, with plenty of smaller fruit. *Kirklees Hall* was the most handsome fruit, and *Empress Eugénie* the longest.

The plants may be trained downwards to meet the pot Vines, and also to the top of the house. A few laths nailed to the rafters will form an excellent trellis. After the first crop of fruit is cut a top-dressing of fresh sheep dung should be given; this, together with occasional waterings of liquid manure, will keep the plants in full vigour as long as they are required, and cause the fruit to be fully developed. Should this be neglected, the plants will soon languish, and the fruit become deformed. As economy is the order of the day in this case, I would recommend *Rhubarb* pots, which have been used during the winter months for their legitimate purpose; these inverted will do admirably, and will want but little drainage, as they have neither bottom nor top.

It will be seen that I have refrained as much as possible from entering upon cultural details, as the culture of all the plants named has been fully given in past numbers of "our Journal." I shall be glad, however, if these few remarks should call forth any additional hints which others may have to offer on this subject.—EDWARD LUCKHURST, *Egerton House Gardens, Kent.*

ASPARAGUS CULTURE.

(Continued from Vol. XIII., page 441.)

In marking-out the beds it is well to arrange so that some of them shall run east and west, and present their sides to the sun's rays when these are most direct and powerful, for in this way they have greater effect than when the beds run north and south, and the consequence is the heads are produced somewhat earlier than in beds having their ends to the sun's rays at mid-day. The beds most likely to afford an early produce are those 3 feet wide, and they should run east and west. For the general supply it is quite immaterial whether the beds run east and west, or north and south.

The beds and alleys being marked out at the requisite distance, a stout peg of some durable wood, as oak or elm (but not the sap wood, as that decays quite as soon as larch), should be driven in at each corner of the beds; the pegs ought to be of sufficient length to be firm in the ground, and yet have their tops 6 inches above its surface, and they will for a number of years indicate the position of the beds and alleys. From the stakes or pegs the distances for the rows are to be measured; and a line being stretched, a trench should be cut out as for laying Box, only it will need to be made deeper, so that the roots may be laid out straight without bending, or doubling-up their ends. On the other side of the line a corresponding cut or trench should be made, which will leave a sharp ridge, both the cuts being made in a slanting manner from the line. The trenches will require to be about 9 inches deep. The planter should take half the roots in one hand, and half in the other, place the plant astride the ridge, and spread out the roots like a fan against the sides of the cuts. A little fine soil should be drawn over the roots, and the trenches or cuts ought to be filled level with the crowns of the plants with some light sandy soil, enriched by mixing with it an equal quantity of leaf mould and well-rotted manure. This will prove very beneficial to the plants; but if the soil is naturally light and rich this compost may be dispensed with, only it is well to cover the roots in all cases with some decomposed vegetable matter, making it pretty firm about the roots. In planting, come are content to make but one cut, and spread out the roots like a fan against the cut. This answers very well; indeed, there are many ways of planting, but the two named I think best.

In planting, the crowns of the plants should be kept all on the same level, and they ought to be covered with 2 inches of fine soil, or be kept that depth below the surface. The plants ought to be carefully taken up with a fork, preserving the roots as entire as possible; and they should be kept as little exposed to the air as can be, so that they may not become dried—indeed, they ought to be immediately covered when taken up, and when planted no time should be lost in covering them with soil. A good watering should be given after planting, and the plantation must be well watered for ten days or a fortnight, unless the weather be showery. Planting ought not to be done when the ground is very wet; showery weather is best.

The best time to plant Asparagus is when the plants have begun to grow, and have shoots from 6 to 10 inches in length. The beginning of May is a very good time, and they may be safely planted up to the middle of June. I am aware that March is the usual time for planting Asparagus, and to doing so then there is little objection if the soil is light and dry; but when it is cold and wet, as it very often is in March, many of the roots perish before vegetation begins. When planting is performed from May to the beginning of June, the plants' juices are active and the soil warm: hence immediate growth is encouraged. Planting in March, so far as my experience goes, is attended with gaps in the rows, no matter how well the operation is performed, and how great the after-care; whilst planting in May or June insures every plant growing and making more progress than those planted two months earlier. In replacing plants failing in plantations made in March by fresh plants in June, with shoots 8 inches to a foot in length, there is a vast difference in the growth; for although those planted in June may wither and turn brown at the top, they

invariably make a better and stronger growth, and are easily distinguished from the March-planted. Under these circumstances I am persuaded that Asparagus is best planted when it is growing freely.

The best plants are those one year old, but two-year-old plants succeed admirably in soils favourable for Asparagus culture, whilst in unfavourable soils one-year-old plants are best. In light soils I would employ two-year-old plants, and in heavy soils those one year old.

The plants are raised from seed, which should be sown in good, rich, light, sandy soil in the beginning of April. It is best sown in drills; five in a 4-foot bed, the two outer drills 6 inches from the sides of the beds, and the three inner drills 9 inches apart. One-foot alleys will be sufficient to allow between the beds. The drills may be made from half an inch to three-quarters of an inch deep, and should be covered or filled with fine soil when the seed is sown, as it ought to be before the drills become dry. Sow it thinly rather than thickly. The beds should be kept clear of weeds, and the plants should be thinned-out to 2 inches apart, the strongest being retained.

As to kind or sort, it is known that there is but one sort of Asparagus. The Gravesend, Mortlake, Deptford, Reading, Battersea, Grayson's Giant, Dutch Red-topped and Green-topped, are all simple varieties of the same plant, due to the variation of soil, situation, climate, and culture, one or other of which induces different appearances.

Instead of sowing and rearing the plants in nursery beds, and afterwards transplanting them when one or two years old into permanent beds, seed may be sown in the first instance in shallow drills at the distances already named for the rows of plants; and the seeds being sown about an inch apart, they should be covered with half an inch of fine soil. The seedlings ought to be thinned-out, when 2 or 3 inches in height, to a distance of 1 foot in the rows, the strongest plants being left, and the weakest taken out. It will be the fourth year before the plants will be of sufficient strength to furnish Asparagus. Beds thus made are quite equal to those planted with one or two-year-old plants, and come into bearing quite as soon, only there is for the first year an apparently great waste of ground; but this may be entirely avoided by taking a crop of Onions the first year, and a good row of Cauliflower may be had in each of the alleys.

In the year of planting little will be required beyond keeping the beds clear of weeds, frequently stirring the surface, taking care at the same time not to injure the crowns with the hoe, nor to go so deep as to injure the roots. In June the beds may be well watered with liquid manure, and the application may be repeated once a-week during any dry periods that may occur in July and August. When the stalks are completely yellow and withered in autumn, the surface should be lightly stirred, and then receive a dressing of 3 inches thick of half-rotten short manure, which ought to be covered about 1 inch deep with soil from the alleys. Towards the close of February the beds should be forked over carefully, not going so deep as to injure the crowns, and the whole left rough. At the close of March or early in April, according to the earliness or backwardness of the season, the soil of the beds ought to be stirred, making it fine with a fork and raking, the rough lumps being drawn off into the alleys. Lame-off the beds afresh, after making them level for their full width, and fork over the alleys; and these and the beds having been made straight, the plantation will have a neat appearance. This brings us to the end of the first year after planting.—G. ARLEY.

(To be continued.)

WINTER-FLOWERING PLANTS.

It is very pleasing to observe the interest taken in winter-blooming plants by the contributors to the Journal; I think such plants are an acquisition to any collection. Even Wallflowers have come in for their meed of praise, and, humble as they are, they have held a high place in my estimation for a number of years. I cultivate the German varieties from seed, and several of the old, many-coloured, double varieties, but especially the orange. These I strike from cuttings in the spring in heat, grow them on, stop them once during the summer, which causes them to throw out side shoots, and pot them as may be necessary, keeping them plunged in coal ashes, and supplying them with water as they require it; sturdy growth is thus encouraged, and in the autumn they are placed in a cold pit. As they throw up their spikes of bloom, they are removed to the

greenhouse or conservatory to perfume the atmosphere. When they have done blooming in the spring I cut them down or throw them away, but old plants when well cared for often do well for years.

Another very desirable winter-blooming plant is *Jasminum nudiflorum*, which can be made to assume any shape you please as a bush or a climber. Though common, it is, nevertheless, useful and ornamental, brightening-up any dull corner with its lively orange blossoms.

Abelia uniflora is another very useful winter-flowering plant of easy culture. It can be grown in a compost of turfy loam, leaf mould, and sand, in well-drained pots, and will well repay the cultivator for his care, by producing a profusion of lilac-coloured *Pentstemon*-like flowers in succession all through the winter.

EVERGREENS IN HOUSES.

WHEN the days are at the shortest, and the long dark nights herald in but little of sunshine, and the old year is near its dying-out, then we think of an ancient almost universal custom in Christian countries, that of bringing in evergreens from the woods to adorn our houses. Not only our homes, but churches, chapels, theatres, concert rooms, every place, we try to make glad with the growth of the summer we have left behind. We bring in the Ivy, the Laurel, the Holly, and the Pine—anything and everything that will not fade before the bitter cold blasts of winter. We count nothing trouble, and spare no expense according to our means, to brighten-up our homes, be they rich or poor.

Varying taste and skill find expression in how we do all this. Some gather the dark branches together and hang them up in hall or corridor, a heavy, shapeless bundle, as if for it to be there were enough, and with no feeling akin to that which prompted the heathen in the old time to arrange for his gods to see. Others put it here, and there, and everywhere, until comfort is invaded, and yet no good effect gained. Others make of it a work of art, with great care join dark leaves and light together, relieved by scarlet berries, thus making a delicate tracery for door, window, or arch, or small-leaved wreaths for picture, bust, or statue.

All do not share in this home decoration with the same enthusiasm, some think nothing of it, and so make little do, and then only as complying with a custom. Save for custom sake they would not mind if their homes stood out bare and leafless as the trees outside; and what is worse, they have no sympathy with those who do it, call it mere child's play and make-work, and not worth the trouble and expense, just for a few weeks; yet the same people never count the cost of a ball or banquet which is but for a few hours. Some content themselves with twining a few sprigs among the gas burners, not minding if they darken the dinner table below, and throw strange shadows on the faces of their guests; whilst some, again, thrust sprays in the windows between the sashes, making them holdfasts against the storms which are sure to come.

Then there are some who object to decoration on the plea of its spoiling their houses, like Mr. Butler, who, having bought a new house for his bride, fears it will not last out their time, and trembles at the sound of a hammer, lest a tack should be driven into his boards, or a nail into his walls; and is sure that a *Camellia* from the conservatory would do just as well as a cartload of evergreens. But his wife, unwilling that their pretty home should be unadorned, and yet mindful of the lately taken though low-spoken vow, brings all her skill and ingenuity to work, and spends uncounted hours sewing small pieces of Laurel, or Pine, or Ivy, to a broad strong band of

calico, which is then passed in and out among the pillars supporting the staircase handrail. A large Fern crowns the summit, and the whole is done with the aid of a thick needle. Though her husband admired her taste, seeing his wish had been obeyed and his property was uninjured, yet her mother thought it "very useless work, all very well if she had the time. Married people did not always have much to spare. For her part she thought it quite enough to put a bunch of Holly with berries on the plum pudding."

"Yes," replied her son, "and let it burn away with the brandy."

There are, too, some people who overdo the decoration, crowding every available corner with heavy branches. With them it is quantity, not quality—like the Doctor up at the Old Lodge, who darkens his windows, and spoils his paintings, and laughs at his wife when she becomes cross, and declares "there is no good in it; for no sooner is the house cleaned down than in comes a lot of dirty, sooty evergreens, with which the whole place is grimed over. Fingernails, large and broad enough for a day labourer, are left upon chairs, walls, and everything; and what is worse, his poor patients are not visited. It might be all very well to house-decorate down in the south about London, where the plants are clean, and where the evergreens are green, not black, as they are about the Old Lodge."

And then there are some who would not on any account take evergreens into the homes of those who were suffering from a near loss; not that they are indifferent to the legend, or fancy themselves beyond the reach of its blessing, but from a seeming perverted idea "that it is not right to do so."

Few are like the Scotch gardener, who used to spend many evenings providing evergreens, and would have no place go unadorned. It is said that in his enthusiasm he one winter hung a large piece of Pine over the ale barrel. Fine pieces of *Aucuba* he used to send in for the parlour, with leaves broad and bright, and as beautifully painted as those of a *Croton*; and he used to say, "They would be as much thought of if they were less strong and hardy; and for winter uses they were worth a vast deal more, for they would brave all the tempests that blow over our island, while the *Croton* would not survive the first breath below 32°." Nor did other places go unremembered: even the kitchen must have its huge bunch hung up over the new bacon, "to flavour it as it dried-in." Stable, outhouse, and greenhouse, everywhere was there some reminder of the festive time.

Then there was the little maiden who, a stranger to our northern ways, ever took away the finest bunch of Holly to put over the bee hives, to let the bees know Christmas had come, "lest there should be no luck in the coming summer, for offended bees make no honey, and where she came from they told the bees everything."

And then there is the Grange, a grand place enough in its way, yet nearly squeezed in at its centre, certainly much air kept out of it, by the big Portugal Laurels, and Hollies, and the like, grown so near to it, that the wonder is their roots have not moved it before this. Why the boys and girls living there care for no evergreens to decorate with, save the Mistletoe, and no wonder, they see so much all the year round. Their good mother ever affirms that the only berries that never stain, however hard they be trodden down into the carpets, are the white berries of the Mistletoe, and truly within its influence we all make merry, if there is any mirth left in us, and would not that our evergreens should ever miss their complement: though, as the youngest Grange girl says, "Kisses at Christmas under the Mistletoe do not mean anything but fun, so she is not sure she cares about them."

So with the thought that it is not only an old custom but a glad thing to do, may we ever brighten-up our homes to their very utmost at Christmas-tide, for the sake of our friends as well as our own. Let us to try to hang up our evergreens with a deeper joy and a fuller reverence as the years pass. Ah! hang them up in very gladness, whatever be our surroundings, for they will show forth as brightly in road-side cottage as in stately mansion.—MAY.

THE MISTLETOE IN FRANCE.

IN Mr. Robson's interesting paper on the Mistletoe, lately published in the Journal, I observe that he remarks—"I believe that the Mistletoe is more plentiful in England than in any other country. I think I have heard of its growing in the north-west of France, but less plentifully than in some of the

south-western counties of England." With regard to this, I beg to assure Mr. Robson that the Mistletoe grows in this neighbourhood (St. Malo, Brittany), in such abundance, as, I believe, is not to be equalled in any county in England. Vast quantities are sent over from this port to Southampton by the London and South-Western Company's steamers during the Christmas season. It is consigned to merchants in London as a regular article of export; and one would suppose that more than enough of it is sent away from this country to supply all the purchasers in that metropolis.

Its beauty is also equal to its abundance. We have cut from a small plot of ground adjoining our house small trees of Mistletoe, perfect in form, and with pearly berries as numerous as the leaves. The country at this moment is green with the Mistletoe; it affords an agreeable relief to the eye from the otherwise bare and leafless aspect of Nature. It is to be regretted that its growth should be so pernicious to the Apple trees, which, in the depth of winter, it clothes with its deceitful verdure.

I have seen it also in abundance in all parts of Normandy, near Avranches, St. Lô, Caen, where it grows freely on the trees bordering the canal, and at Houdéur, from which exquisite neighbourhood it is also exported to England, although not, I think, in such quantities as from St. Malo. Judging, therefore, from its abundance in these last-named localities, I am inclined to believe that the Mistletoe loves the sea breeze, and that the vicinity of the ocean is, at least, not unfavourable to its growth; thus arriving at a conclusion exactly opposite to that of your esteemed correspondent.

A certain degree of moisture in the air and in the earth seems essential to its existence; must we add, a certain want of cultivation of the soil also? In all the places that I have named the standard of agriculture is far below that of England; and I shall be glad to learn from those better informed than myself whether the Mistletoe is ever found where the soil receives high cultivation. I am myself an ardent admirer of this beautiful parasite, and I fear that the appearance of the draining machine will be the signal for the extinction of this once highly venerated and ever mysterious plant of "merry Christmas."—A TRUE BRITON, *St. Malo, Brittany*.

[The Editors are very much obliged by this communication. Will the writer oblige them by sending her full address?]

GYMNOSTACHYUM VERSCHAFFELTI.

PERHAPS a few hints upon growing this beautiful-leaved plant may not be out of place for the guidance of the amateur.

The compost which we use consists of about equal parts of turfy peat and loam, with a good mixture of silver sand.

It strikes very freely in river sand if afforded a bottom heat of from 70° to 75°.

It requires a gentle bottom heat; and covering the plant with a hand-glass much improves its appearance, keeping the foliage from lying so flat, as it is otherwise very apt to do. The plant requires a good supply of moisture. It throws out roots at nearly every joint, and succeeds remarkably well in a propagating pan, as the young shoots can then be pegged-down and will soon strike roots into the soil.

We planted a spring-struck cutting of 1867 last summer, in a propagating pan, pegged all the shoots down excepting one that was left for a leader, then covered the surface of the soil with moss, and subjected it to the treatment above described. This plant now measures about 8 feet in circumference, and stands about 2 feet high.—JAMES TAYLOR, *Foreman, Womersley Gardens, Yorkshire*.

CUTTING OFF BLOOMS AND PRUNING ROSES.

THE following are queries from a correspondent ("Q. Q."), with Mr. Radclyffe's replies.

"Mr. Radclyffe says he does not approve of cutting off the blooms of Hybrid Perpetuals, as he has found that many of his, cut for exhibitions and bouquets, have greatly suffered by such treatment. Does this apply only to the Rose being cut down to solid wood, or is it also bad simply to nip off the blossom itself with its flower stem? I hope not, for one of the great pleasures of Roses—having them in-doors—would be thus annihilated. This question applies both to Briar and Manetti Roses."

[There is no doubt that in France seed-formation, and, in cold England, flower-formation and dropping of the flower, are Nature's

terminus, and conducive to maturity of wood. If first flowers are cut off, and a severe winter succeeds the summer without a intervening autumn, as in 1860, the wood would not stand the winter so well as if the first centre flowers had been allowed to drop off. You might take off a bloom here and there, and leave, in the case of a truss, some one or more blooms to expand and drop; or you may let the centre bloom drop, and when the other flowers of the truss expand cut off the whole truss.]

"After the whole truss of blossom has decayed, is it good to cut the whole stemlet down to a healthy bud?"

[It will do no harm, and perhaps hasten the next series of bloom on that stem. The next series may be cut off the secondary wood at any time without harm, because it may be presumed that the first wood, which will be for next year's performances, is ripe. In short, always try to have a certain portion of wood ripe. Manetti Rose wood does not require so much ripening as that of Briar Roses. The most immature wood will bloom on the Manetti. The object of obtaining mature wood is to stand a severe winter. I do not trouble myself to cut off the truss of bloom unless it is unsightly. My trees are in such condition that they will break below the truss, and bloom quickly again. Nothing but frost stops them.]

"Are Tea and Tea-scented Noisette Roses also injured by cutting off their first bloom? The question applies both to those on the Briar and Manetti stock."

[These families do not like much cutting at any time. They require at times thinning-out, and the points of the main shoots to be cut to a good eye, and the side branches shortened a little to a good eye.]

"What mode of treatment would be best to adopt with the March prunings of Roses in order to make them strike?"

[September is a better time to strike the cuttings of Roses out of doors than March; because in the former case the earth is still hot and the air cool, whereas in March the earth is cold and the air hot. I should advise taking off some shoots with a heel, daubing the base with cow dung, which is very favourable to the formation of roots, and then planting the cuttings under a north wall or shady place, as the sun might dry them up before they could strike. Sand also greatly promotes root-making. If I have a Rose root-sick I dig it up, cut its roots back, and put a double handful of sand over the roots, and then decayed dung and soil, and it generally makes an abundance of roots in a little time. If this is done in summer I place a cloth over the Rose. The hotter the weather is the quicker Manetti will strike.]

"Will Mr. Radclyffe name six Roses of the Général Jacqueminot colour possessing advantages over that Rose, noticing which he considers—Séateur Vaisse or Madame V. Verdier—the best Rose to have a number of for one bed?"

[It is difficult to name Roses exactly of one colour. Séateur Vaisse is perhaps on the whole better than Madame Victor Verdier. They are, however, both admirable. The nearest, perhaps, to the Général in colour are Maurice Bernardin, first-rate; Séateur Vaisse, Madame Victor Verdier, Madame Bontin, Duchesse de Caylus, Madame Julie Daran, and Maréchal Vaillant. Darker than these are Charles Lefebvre and Lord Macaulay, both first-rate. If rosy or lighter crimson is not objected to, Lady Suffield is very beautiful and excellent. They are all fit for beds, and, of proven Roses, in their colour the cream up to this time. A bed of Jules Margottin, light crimson, is fine.]

"Does Mr. Radclyffe think that there is sufficient difference between Céline Forestier and Triomphe de Rennes to admit them on the same wall?"

[Yes: the foliage of Céline Forestier is distinct from all known Roses. I have many of both these, 12 feet high, against my south frontage. They are among the best Roses in the Rose kingdom. The blooms are sometimes, but not usually, alike.]

"Would charcoal strewn over the surface of the ground prevent mildew?"

[I should think not. The best way to prevent mildew is to give the plants, in hot weather, plenty of water over their roots and foliage. You never see much mildew or many aphides after a thunderstorm.—W. F. RADCLYFFE.]

ORNAMENTAL-FOLIAGED PELARGONIUMS.

VARIOUS have been the suggestions of your correspondents as to the classification of variegated Pelargoniums, yet no one seems to have hit upon a proper term whereby to designate them as a whole. That which I propose, "Ornamental-foliaged," is almost a household word with gardeners. I beg to offer it for the consideration of perplexed floral and horticultural committees revising their schedules for 1868; and if adopted it will be the means of restoring Beauty of Oulton and other varieties of that section, to their proper position of plants grown for their foliage, and as such worthy to be placed on a

par with Flower of the Day and Golden Chain. I have no doubt there would be many a fine plant of Beauty of Oulton, Luna, and other kinds left at home, and, very probably, something more commonplace substituted, in consequence of the decision of the Floral Committee of the Royal Horticultural Society on the 2nd of July last causing no little disappointment in various parts of the country.

I am unable to see any benefit to be derived from separating the section to which Beauty of Oulton belongs from the others at general exhibitions, but think there is much harm, especially at the smaller shows, where there will not be more than one class for variegated Pelargoniums. At these exhibitions the so-called Golden Zonals will be practically excluded; and where they may have a separate class assigned to them, I think they present too great a family likeness to be properly appreciated by the outside public. In fact, your remarks on the Pelargonium Exhibition held on the 17th of September pointed this defect out.

I do not wish to depreciate these special exhibitions: far from it. I think they are excellent as a means to determine the best varieties in each section; but when this is done we want to see the best of each section meet on one common ground, or under one general term. This, I believe, will be best accomplished by the designation I have suggested. It will admit all that are out, and all that have to come yet, as varieties that are grown for their foliage in contradistinction to those that are grown for their flowers, be that foliage black, brown, yellow, or white, or all combined.

To put the question in a more popular point of view: supposing that I have ten specimens of the Golden Zonals, and ten of what are called the true variegated Pelargoniums, would not the general effect be greatly improved by judiciously arranging the twenty plants together in one lot rather than by separating them into two, drawing the line at some supposed difference between coloration and variegation?—JOHN COUPLAND

GRAFTING THE VINE.

THERE have been a few letters in the Journal on grafting the Vine, and in all that has been written on the subject I have been much interested; yet it seems to me that a little more information ought to be forthcoming from those who have had experience in the practice.

Suitable stocks have been found for the Apple, Pear, and other fruit trees; those stocks are propagated by thousands, and the different effects of the stock on the tree grafted thereon are most surprising.

I have two Louise Bonne Pear trees growing in the same row, one on the Quince stock, the other on the Pear; and the result is that the Pears from the Quince stock are much larger than they are from the Pear stock.

Again, the Marie Louise does not succeed on the Quince, but does well on the Pear stock.

I hope some day to hear of a stock for the Vine which will influence the plant as much as the Quince has the Pear, the Paradise stock the Apple, and the Mahaleb stock the Cherry.

My experience of Vine-grafting is not very extensive. I have never, however, been able to effect a union by performing the operation when both the stock and scion were in a dormant state. In the spring of 1867 I had a number of Black Hamburgh Vines in pots. These I grafted with Muscats and Gros Guillaume. At the same time and under the same circumstances I grafted Pears, Oranges, and Camellias. They were then plunged in bottom heat, but the Vines failed and the others succeeded. The Vines soon began to bleed, and some of the scions made roots in the grafting clay, but in no case was a union effected. However, not to be foiled, I grew some stocks and plants of the variety I wanted to graft, inarched them in the summer, and I found no difficulty in effecting a union in that way. I placed both pots together, cut a slice off the stock and another from the scion, and tied the cut parts together in the months of June and July.

I believe the Black Hamburgh to be a good stock for some varieties. The Canon Hall Muscat succeeds on it, and, as is well known, so does the Black Muscat of Alexandria. I have, however, seen the Red Frontignan and Chasselas Musqué grafted on it without perceiving any improvement. The former was as liable to shank and the latter to crack as they were on their own roots.

Grafting Vines seems to have been well understood a century ago. Speechly, the Duke of Portland's gardener at Welbeck in

1759, speaks of a Syrian Vine in the hothouse there, which had on it sixteen different varieties of Grapea; and he further says that by grafting a weak and delicate-growing Vine, such as the Blue Frontignan, upon a robust and vigorous stock, as the Syrian, it will produce well-sized handsome bunches as large as the Hamburgh; and that "the Syrian Vine raised from seeds is greatly preferable to all others for stocks." He must have had a good variety of Syrian, as it is recorded that he grew a bunch of it weighing 20 lbs.—J. DOUGLAS.

PROPAGATING PELARGONIUMS.

In your issue of December 26th I noticed Mr. Stewart's reply to Mr. Perkins. In course of his (Mr. Stewart's) remarks, he has made a reference to what appeared from me on page 277. I wish to correct a mistake that Mr. Stewart has fallen into—it was Golden Chain and it alone I spoke of, not the strong-growing varieties of bedding Pelargoniums. I have no wish to be implicated in the controversy, because I think it is a mere matter of fancy and convenience, known only to oneself, how, when, and where to put in cuttings of Tom Thumb, &c. It is a well-known fact that there is nothing more easy and simple than propagating the common bedding Pelargoniums.

I was truly pleased to learn from Mr. Stewart, on page 419, that he found so little trouble in getting-up Golden Chain. I wish I could say the same. What a boon it would be to me! I fancy I can hear my wish passing from the lips of many a gardener, but I am afraid the wish will be all that will fall to our share.

Not having had an opportunity of seeing Mr. Stewart's method as carried on by him at Nuneham, I must, of course, take his word; but can it be that he can put-in cuttings of Golden Chain in the last week in August, and secure sufficient for his trouble, and have well-furnished plants for planting-out in the following May? It may be unjust of me to doubt the authority of Mr. Stewart, for there are examples of men who can solve a problem in an hour, while it takes others years to do so.

I will some future day put Mr. Stewart on a way of obtaining cuttings of Golden Chain to keep up his stock, without at all interfering with the plants in the flower beds, as that seems to be the sole point that he is working on.—R. E., Womersley Park, Yorkshire.

A FEW NOTES ON DRACÆNAS.

OF all the plants which have from time to time been introduced into this country from the tropical and sub-tropical zones, those of the genus *Dracæna* are, perhaps, among the most lovely; for what plant surpasses in richness of foliage the *Dracæna terminalis* (Ti plant), and its handsome variety *latifolia pendula*? The former expands a long tapering pendulous leaf with a very dark ground colour, and marked with distinct lines of vivid crimson; while the latter has leaves of a pendulous and reflexed character, broader and more obtuse than those of the former, with distinct lines running the entire length of the leaf. *Dracæna Cooperi* is very similar to the last-described.

The East Indies, as well as tropical Africa, appear to be eminently rich in *Dracænas*, many of which are valuable for medicinal purposes, and as being farinaceous and edible. Around the huts of the natives an extremely ornamental fence is made by planting the *Dracæna terminalis*, which is not allowed to reach more than 5 feet in height. The tuberous roots abound in starch and sugar, and a spirituous liquor is likewise obtained from them by fermentation. The stems when cut down and stuck in the ground soon send out new roots.

In the gardens of the Marquis de Souza, at the little town of Oratava, is the celebrated gigantic Dragon tree, which ten men by joining hands can scarcely surround at the base. In the year 1400, when the island was first visited by Europeans, this great tree was, as it is now, a wonder. Precise accounts of the dimensions of this great Dragon tree have been handed down to us, and it appears that since the island of Tenerife was first discovered this tree has added but little to its bulk. Indeed, the slow growth of young Dragon trees is a proof sufficiently convincing that the age of this particular tree must be extraordinarily great. In the Palm house at Dangstein, near Petersfield, is a plant 12 feet high, raised from a cutting taken about twelve years ago from this venerable tree; and in the

musum there is a true picture of the same, drawn on the spot by Mr. J. J. Williams, which figures the tree with the branch that was taken off expressly for Mr. Skinner, who afterwards presented it to Lady Dorothy Nevill. The base of the branch from which this plant was taken is preserved in the museum at Kew.

Humboldt gives an accurate account of the famous *Oratava* specimen, which he informs us is 75 feet high and 45 feet in circumference. Sir George Staunton also described one he saw (which I believe to be the same), as being 12 feet in diameter at 10 feet from the ground.

The *Dracena draco* is supposed to be originally a native of the East Indies, and to have been subsequently introduced into the Canary Islands, consequently, to quote Rhind's words, "the high veneration in which it is held by the Guanches of these islands would indicate its introduction there from the Indian continent, as also the original country of the primitive inhabitants of the Canary Islands."

The resinous matter called dragon's blood is yielded in great abundance by this plant, from the surface of the leaves and from the cracks in the trunk. It is of a fine dark cinnamon or Indian red colour, and is tasteless and almost inodorous. Its fracture is glossy, and its powder of a deep crimson hue.

Having thus briefly noted the history of the *Dracena*, I will now offer a few cultural remarks.

The *Dracenas* are usually cut down whenever disposed to become too tall, because, being branchless, their beauty is lost if the plants are allowed to grow till they lose their compactness. Of course, in cutting them in, the natural height of the species must be taken into consideration. Such plants as *Dracena bicolor*, *elliptica*, *striata*, and *ovata*, are of dwarf growth; while *Dracena terminalis*, *ferrea*, and *purpurea*, attain a height of from 9 to 15 feet. All of these, with the exception of *Dracena draco*, when becoming unsightly through lankness, should be cut back in order to obtain the former compact form.

Young plants are, however, much preferable to the old ones, and these may be easily obtained by cuttings taken from the summits of the old plants, and treated similarly to other fine-foliaged plants. Large branches of the *Dracena draco* strike very readily when placed in a brisk bottom heat. The pots should be well drained, and the compost should consist of equal parts of rich fibrous loam, peat, and leaf mould, with a good sprinkling of silver sand. The loam and peat may be pulled to pieces by the hand, and the leaf mould sifted through a coarse sieve.

In summer, when the plants are in active growth, they require an abundance of moisture, both at the root and in the atmosphere, with a tolerable amount of air; but in winter these conditions must be almost reversed, preserving then a moderately dry atmosphere, and no more water at the root than just enough to maintain the plants in a healthy state. A summer temperature of from 60° to 75°, with a rise from sun heat, suits them; and in winter one of between 50° and 60°, or even less.—GEORGE NEWLYN.

RECOLLECTIONS OF A VISIT TO BERRY HILL.

SITUATED on a gentle acclivity about a mile and a half to the south of the snug little town of Mansfield, is the compact residence of Sir Edward S. Walker, Bart. I had the pleasure of visiting the well-kept gardens attached to it on a lovely morning during the last week in August.

The mansion is a plain unpretending structure, yet containing much more internal accommodation than would be supposed from its outward appearance. The fruit and plant houses are so arranged that they can all be traversed from the mansion without the visitor passing out of doors. A verandah on the west side of the mansion communicates with the conservatory and from thence to the other houses.

The conservatory was the first house to which my attention was drawn, and, as might be expected from Mr. Speed, the skilful head gardener, presented a charming picture. Among the plants in bloom, the most deserving of notice were *Erica tricolor* Wilsoni, *E. Massoni* major, *E. delicata*, *Echmea fulgens*, a choice collection of *Fuchsias* covered with a profusion of flowers, and *Zonal Pelargoniums*. These were blended with Ferns and plants with ornamental foliage, such as *Pandanus javanicus* variegatus, *Aspidistra lurida* variegata, and *Caladiums* in great variety. Of Ferns I noticed pretty plants of *Asplenium bulbiferum*, *Polystichum angulare*, *Pteris tremula*, *P. tricolor*, *Polystichum angulare proliferum*, *Adiantums* of sorts,

and *Dicksonia antarctica*. The last-named ought to be in every collection of greenhouse plants, however limited. Graceful Ferns, and plants with fine foliage or elegant habit, such as *Aralias*, *Dracenas*, *Rhopalas*, *Ficuses*, *Palms*, &c., are much more refreshing in their appearance, and produce a more striking effect in the embellishment of the conservatory, when skilfully arranged, and interspersed with plants in bloom, than when dumpy and ungraceful flowering plants only are used. On the back wall were five *Camellias*, which promised a rich display of bloom during the winter.

Passing out of the conservatory I entered the early vinery, generally started in December, the first in the range of fruit houses; and as these are all in a continuous line, I shall notice them in the order I passed through them. In this house all the fruit was gathered except about one bunch, which had been left on by way of experiment. The branch on which it was growing had never been stopped, and had rambled away 5 or 6 yards. It has been stated in these pages, and I believe the late Mr. D. Beaton tried to establish the theory, that by allowing the shoot on which a bunch of Grapes is produced to grow on the extension principle it would tend to increase the size of the bunch. It had failed in this case, for Mr. Speed told me that it was nearly the smallest bunch in the house. It is worthy of remark that in the early period of the season the shoot was very weakly, and by allowing it to grow at will it was at its base nearly as thick as a man's finger, which result could not have been attained had it been stopped at the fifth or sixth leaf, which is a very general practice.

From this house I passed through a Nectarine house, cleared of the fruit, into a late vinery. Here the fruit was hanging in splendid bunches all over the house. The varieties cultivated in this house are *Barbarossa*, *Trebbiano*, *Lady Downe's*, *Muscats of Alexandria*, and *Black Hamburgh*. The Grapes were very fine, and such as are rarely excelled. The bunches of *Barbarossa* would average about 7 lbs. each; those of the *Trebbiano* were unusually fine; whilst *Lady Downe's*, for size and symmetry of bunch, left nothing to be desired. The *Muscats* were also very fine, and the bunches would average from 3 to 4 lbs. each.

The next house was devoted entirely to Figs; it was a lean-to. The Fig trees were cultivated in pots in the front, and those on the back wall were grown in the border. From this house Mr. Speed had gathered a continuous supply of fruit from the middle of May until the time of my visit—the end of August.

On leaving this house I entered another late vinery, in which was a very excellent crop of fruit. The bunches were very even and regular in size, and, like those in the other houses, bore ample evidence of Mr. Speed's superior skill in the production of Grapes.

Passing out of the late vinery and through another Peach house, I entered the new large vinery. It is 50 feet long, 19 wide, and 15 high. The whole of the front of the house was planted with *Muscats* of various sorts, and the back wall with *Black Hamburghs* and *Lady Downe's*. The front of the house is built on arches to allow the roots to ramble in the outside border. The border inside and outside is 30 feet wide, is chambered underneath, and heated with hot water. In this house there was a crop of Grapes worth going a long journey to see. The Vines were planted one to each rafter, and one in the centre of each light in the front, and on the back wall they were about 3 feet asunder. All the Vines carried a most abundant, regular, and fine crop of fruit.

The last house in this range is set apart for Pine Apples. It is 75 feet long and 19 wide, with a path running along the centre. It was filled with a fine collection of Pines in all stages of growth, and the plants were characterised rather by thick sturdy foliage than by long lanky leaves, as are too frequently met with. Up the pillars by the sides of the path, Mr. Speed grows his pot Vines.

From this house I passed along a narrow walk into the flower garden. It is bounded on the north side by the range of houses just noticed, and on the south by a belt of fine timber trees, which skirt the park. A broad gravel walk runs from the mansion westward, parallel with the vineries, &c., and is terminated by a rustic summer house. Along each side of the walk is a row of Irish Yews, which form an avenue; and on each side beyond the Yews the beds are cut out in the turf in the form of diamonds and half-diamonds. At the time I saw them the beds were very gay; and if I may remark on the individual beauty of any bed, it must be on that of *Coleus Verschaffelti*, one of the most gorgeous bedding plants at present known, as recently stated by your correspondent Mr. .

Rawbone. Nothing could surpass the richness of its velvety foliage; and as I happened to call on one of the finest mornings we had been privileged with during the summer, I saw the beds in their very best trim. The most useful varieties of Pelargoniums out of the ordinary run were Lord Palmerston, with lake-coloured flowers tinted with crimson, and fine bold trusses; also a variegated form of Stella. I suppose it to be a sport from that popular variety. Its leaves were very much cupped, with a very clear, broad, white margin; the bright crimson scarlet trusses of bloom were borne well above the foliage on long flower scapes. Standing a little distance from the beds, the broad white margin of the leaves being so prominent, very little of the green surface of the leaves was to be seen.

I left the flower garden by a shady walk, bordered on each side with rockwork, on which were growing hardy Ferns and other plants adapted to shaded and moist localities. This zigzag walk opens into a wide open space on the south side of the enclosed kitchen garden. There is a walk, 160 yards long, which runs the whole length of the garden, with a ribbon border on each side. The right-hand border was planted with *Cerastium tomentosum* in front; second, Cloth of Gold Pelargonium and Purple King Verbena alternately, and Stella Nosegay Pelargonium at the back. The left-hand border had *Cerastium tomentosum* in front; the second row was *Lobelia speciosa*, Cloth of Gold Pelargonium, and Iresine Herbstii repeated the whole length; the third row, *Gladiolus*. This border was truly beautiful. Behind the *Gladiolus*es was a row of standard and dwarf Roses alternately, and the stray Roses of Gloire de Dijon, Souvenir de la Malmaison, Général Jacqueminot, &c., which overhung the *Gladiolus*es relieved the ribbon lines from that stiffness which too often prevails in this style of planting. I had the gratification of seeing the *Gladiolus*es at their best, and they alone were worth my journey.

I must pass through the kitchen garden with a hasty glance. It is two acres in extent, and surrounded with well-built brick walls, and these were furnished with useful fruit trees, fine examples of training. Indeed, I have not seen any in the district trained with such exactness, except at Lord Middleton's at Wollaton Park, under the superintendence of Mr. Gadd. Round the kitchen garden were numbers of pyramidal Apple and Pear trees in excellent condition for bearing. The garden appeared very fertile, and fine crops of vegetables of every description were plentiful. I noticed several rows of Veitch's Perfection Pea, which had been nearly destroyed by the snake millipede (*Julus pulchellus*), which Mr. Speed had experienced some trouble in exterminating; other rows not attacked by the millipede supplied plentiful gatherings.

Leaving the kitchen garden we entered an enclosure, in which were a number of useful small span-roofed houses. Some were occupied with successional Pines, others with early and late Melons and Cucumbers, stove plants and Ferns, and one very useful house was filled with greenhouse plants preparatory to blooming in the conservatory. There was a temporary stage that could be readily taken away, and the house filled either with tall-growing plants or with those of dwarf growth. Besides these there were numerous frames filled with *Cinerarias* and other plants, all valuable in their respective seasons of bloom. Many hardwooded plants, such as *Azaleas*, *Heaths*, and *Epacris*es, were either placed on or plunged in cinder ashes, all being in perfect health and vigour, fully proving the fact that Mr. Speed not only grows fine Grapes, but develops superior skill in the cultivation of plants. I noticed in particular in 12-inch pots a very fine lot of *Chrysanthemums* all well grown, and every branch staked and tied-out with the utmost care.—QUINTIN REED, *Gardener to W. Hollins, Esq.*

MY EXPERIENCE OF AN ARNOTT'S STOVE.

THERE can be little doubt that the amateurs and lovers of gardening who are anxious to possess a glass structure of their own, are each year increasing in number. There can be little doubt also, that the most formidable impediment in the way of carrying out their wishes is not the immediate outlay which is necessitated in erecting the structure, but the yearly expense which must be incurred for fuel. This, in the very nature of the case, must have a powerfully deterring effect, and is the Rubicon which many an amateur enthusiast hesitates to ford. Now, in my remarks on this subject I can advance no new theory of heating, my object being simply to take a practical walk on an old, very old, and comparatively unused path, and endeavour to clear it of a few briars, which, in these days of

hot-water travelling, have been suffered to ramble comparatively undisturbed across it, making it, if not unsafe, certainly unpopular.

For long ranges of glass and houses especially devoted to early forcing, the hot-water system of heating has no rival, but for a solitary structure erected in the garden of an amateur for the purpose of keeping bedding plants and growing a few Grapes, I recommend Arnott's stove, as calculated to answer all his purposes efficiently, and more economically than any other mode he can adopt. This, I am aware, is only confirmatory of what has repeatedly been advised in the Journal, but if my experience on this head can have the slightest re-assuring effect, the purpose of my paper will be attained.

Under my charge are two vineries heated by Arnott's stoves. I will instance one house: it is 6 feet high at the front, 11 feet high at the back, 14 feet wide, and 18 feet long. This house is heated by an Arnott's stove placed against and about the centre of the back wall. The stove is 18 inches square and 2 feet 6 inches high. The smoke pipe is carried 18 inches horizontally; it then takes a vertical position for about 5 feet, turning again horizontally into a chimney in the back wall. This is better than taking it upright through the glass, as being out of the way of the foliage of the Vines on the roof. More than twenty-five years ago this stove cost £4, and during this period a few shillings may have been incurred in repairs, but these have been extremely trifling. For a number of years the gas coke consumed was carefully noted, and it never amounted to 15s. per stove per annum. This is an outlay which I apprehend the most economical need not be frightened at. Even this first outlay of £4 may be reduced, for a handy bricklayer and smith would, according to the ordinary charges, put up one for a less amount than the sum named.

The mode of erecting a stove of this class I will endeavour to describe.

Procure a plate of half-inch cast iron having a groove cast in it close to and all round the edge, 18 inches square; on this stand the grate, which should be about 10 inches square, and standing on four iron legs about 4 inches long. (See accompanying section and elevation.) The edge of this stand-grate make the foundation for building; carry up a few firebricks all round to the height of 18 inches, which will give an interior for the fire of 8 inches square by 18 inches deep. Over this space bend an arch of sheet iron. Enclose the whole with a shell of sheet iron, which should fit in the groove in the foundation plate; carry it up to the required height. The cavity between this shell and the brickwork fill with dry sand, bringing it up to and covering completely the top also. Over this place a square of cast iron, cast in the same mould as the foundation plate, and the stove is complete, excepting that an orifice must be left on one side and close to the top for the smoke pipe, and another on the opposite side, only about 6 inches lower, for putting in the fuel; while, of course, at the bottom of the stove must be a square into which the ash box slides, fitting closely under the grate, the door of the box buttoning tightly to the side of the stove, which here should be made additionally strong by rivetting on a strap of one-quarter inch iron quite round the opening. Have a ventilator to assist combustion in the centre of the ash box door, and you have a stove cleanly, efficient, and economical, infinitely superior to an ordinary iron stove, in being dust-proof, and the bricks and sand retaining heat for hours after the fire becomes low, or even after it has gone out altogether. This, however, is a contingency which we do not calculate on here, for by adding necessary fuel night and morning, and paying due regard to the ventilator, the fire may be kept in for weeks or months if required. It is well, however, to let it go out sometimes, to take out any clinkers which will in time form in the grate. This must be done by the hand; if, therefore, any one is afraid of touching a cold clinker with the fingers, he must look to other modes of construction.

Now, as to the capabilities of stoves of this kind, I confess when I first saw them I had not much confidence in their power; and on expressing slight doubts of their efficiency, the proprietor very significantly pointed to the fine crop of Grapes overhead, a mode of reassuring me that admitted of no controversy. Therefore, thinking what had been done before might be done again, I cast aside all prejudice and determined to try what the stove in question really would do, and, indeed, what it would not do, for the negative part of a question is oftentimes instructive.

In the house above named are eight Vines trained up the rafters. These eight Vines give annually about 120 bunches of Grapes of a quality which are appreciated on a nobleman's

table; indeed, I am safe in saying, that they are not inferior to any grown in the neighbourhood under the most elaborate system of heating by hot water. These Grapes we commence

cutting in July. This is as early as it can be accomplished, but is sufficient testimony of the capability of the stove to resist

frost; and notwithstanding that it is placed at the back of the house, so well is the heat diffused and disseminated, that in the most severe weather of winter, *Cinerarias* standing within a few inches of the glass in front have been untouched by frost; but for additional safety, it is only the work of a few moments to remove comparatively tender subjects further into the house. It is, however, but fair to observe, for I wish to be very accurate, that there is always more heat in the back and top part of the house; and notwithstanding every attention of airing and bending the Vines from the immediate neighbourhood of the stove as long a time as possible, the Grapes at the top of the Vines are ripe a week to ten days before those at the bottom of the rafters. The bunches, however, are very regular, and as good at the bottom of the Vines as at the top. I have stated what the stove will do; the owner authorises me to say, that he does not wish to see better Grapes, that he prefers some ripening before the others, and that he has previously sent you a sample of what Grapes can be grown by an Arnott's stove.

I will now introduce the negative, and state what it will not do, or rather what it does not do here, for I am aware there is a list of objections against it.

1st, It fills the house with smoke on lighting the fire. No. Unless it is out of order, the sheet-iron casing being worn through in places, or improper fuel used, there is not the slightest perceptible escape of smoke. Perfectly dry shavings and split wood should always be used in lighting the fire; no harm will then result on this point.

2nd, On attending to the fire a dust is raised which settles on the plants and obstructs their respiratory organs. No. With ordinary care the plants in this house present as clean an appearance as those in an adjoining structure heated by hot water, and there is certainly not so much dust distributed in an entire year from the stove as there is from sweeping the paths and shelves once without the necessary damping previously.

3rd, The heat in close contiguity to the stove is of such a parching and burning nature, that colonies of red spider will find it particularly congenial to their taste, and will, as a consequence, establish themselves in the house. No. The Vines have not for two years had a single dash with the syringe, and during this time not a single red spider has been seen. The evaporating pan on the top of the stove is to a certain extent a preventive of this pest.

4th, The stove in its combustion emits sulphurous and deleterious fumes impregnating the atmosphere of the house, and is in some degree hurtful to vegetation. No. My experience does not teach me this. I will state a fact relevant to this point.

During the spring of last year, while the house was painted, the occupants of a plant stove were transferred to this vinery, in which the Arnott's stove was working. The stove was heated to the utmost in providing a temperature suitable to this class of plants, which consisted of Ferns in active growth, Begonias, *Caladiums*, *Dracenas*, *Gloxinias*, and *Gesneras* in bloom, and other plants of a very tender nature and susceptible of injury from any cause; but after a three-weeks sojourn not a frond of the most delicate Fern, or the texture of a flower so admittedly tender as a *Gesnera* or *Gloxinia*, was in the slightest degree injured or discoloured. Indeed, I could have wished they had remained a week longer, for they did receive a certain amount of injury from the paint on returning to their established quarters.

I need say no more on this subject. I say not a word against hot water; I am fully cognisant of its value as a heating medium, and cheerfully accord to it many advantages and general superiority, but still it does not on all points meet the views or requirements of every class, and as every class looks for information through the columns of the Journal, the experience may suit some one. Therefore, for a small detached house for general purposes, and where Grapes are not required before August, I unhesitatingly recommend Arnott's stove as safe, clean, efficient, and in a pre-eminent degree economical.

As an addendum to this communication, and in order that everything bearing on the case may be made public, I may say that when the greenhouse and plant stove were to be heated by hot water, it occurred to my employer, that instead of having the nuisance of a chimney in the garden, the smoke might be carried across a walk and along the front of the vineries, escaping by a chimney in the back wall of the vinery. This plan has succeeded perfectly. It adds a gentle warmth to the front of the houses, and I have had no trouble from smoke. This does not in the least degree detract from the capability of

the stove, as it answered every requirement for many years before this convenient mode of getting rid of an unsightly object was effected.

My employer says, that in an article on Arnott's stoves a tribute should be paid to Dr. Arnott, who, having discovered how by slow combustion the greatest quantity of heat can be obtained from the smallest quantity of fuel, made known the principle to the public, instead of turning it to his own advantage by a patent. Many stoves called "patent" are constructed on this principle.

A stove similar to the one I have described burns in the lobby of the hall, and distributes a genial warmth throughout the house, and another warms our large parish church.

As gas is made on the premises, we have a constant supply of good coke, but the value consumed in any one stove does not exceed the amount I have named—15s.—J. W.

PEARS.

5. ALTHORP CRASANNE. — A dessert Pear of finest quality. Ripe from October to December. It was raised by T. A. Knight, Esq., and first fruited in 1830.—(*Fruit Manual*, p. 239.)

5. Althorp Crasanne.

6. AMADOTTE.—Fruit medium-sized, 2½ inches wide, and the same in height, of a roundish obovate shape, and flattened at the apex. Skin thin, of a pale green colour, which changes as it ripens to clear lemon yellow; but where exposed to the sun it is of a deeper yellow, and faintly tinged with red. In some parts it is thickly marked with rough, brown, russety dots, particularly round the eye, and sometimes it is entirely covered with fine cinnamon russet, except on some parts that are very much shaded, and then the ground colour appears. Eye half open, with long acuminate segments, and placed in a small and sometimes pretty deep basin. Stalk stout, 1½ inch long, obliquely inserted on the summit of the fruit, with a fleshy protuberance on one side of it. Flesh yellowish white, crisp and juicy, half melting like *Passe Colmar*, and with an unusually sugary, rich, and very strong musky or rather anise flavour, which, as Diel says, "one seldom meets with."

It ripens in the end of October, and continues in use till about the middle or end of December.

The Amadotte has been long known in England. It is one of the varieties which Rea says "are choice Pears lately ob-

tained out of France by the diligence of Sir Thomas Hanmer. It is said to have been discovered in a wood in Burgundy,

6. Amadotte.

belonging to Lady Oudotte, and hence called *Dame Oudotte*, which has since been changed into *Amadotte*."

7. Amande d'Été.

7. AMANDE D'ÉTÉ.—Fruit somewhat about medium-sized 2¾ inches long, and 2¼ wide. It is of an obtuse pyriform shape,

rounded at the apex, and tapering gradually to the stalk, even and regular in its outline. Skin smooth, pale green at first, but changing as it ripens to a pale lemon yellow, without any colour next the sun, and marked with a few traces of thin pale russet. Eye quite open, with short segments, and placed in a very flat and shallow depression. Stalk 1½ inch long, slender and woody, inserted in a small round and narrow cavity. Flesh white, rather firm, not buttery, nor very juicy, sweet, and with a distinct almond flavour and perfume, but with no character in it to merit notice.

An inferior Pear, ripe in the beginning of September, and soon rots at the core.

The tree bears well and regularly, and forms a handsome pyramid on the Quince.

NOTES AND GLEANINGS.

We are happy to hear that the Crown has decided to relieve Mr. INGRAM from the care of the Royal Gardens at Frogmore, an office which he has held with great credit to himself for a period of fifty-four years, and that an ample retiring pension has been conferred upon him. Four years ago, when Mr. Ingram had completed his fiftieth year in the service of the Crown, a number of his friends presented him with a handsome testimonial, as a mark of their esteem for him as a friend, and of their appreciation of those qualities which enabled him to fill for so many years, and during so many reigns, a position of high trust not unattended with some difficulty. During his active career Mr. Ingram has rendered good service to the profession he so much adorned, as is testified by the many varieties of fruits which bear his name and that of the Royal garden, as well as several florists' flowers which have taken a prominent place in our gardens. We congratulate Mr. Ingram on this termination to his long and active labours; and we know that he will carry with him into his retirement the good wishes of his friends and of all with whom he has come in contact in his professional capacity.

— With the beginning of the year a new series of "THE FLORIST AND POMOLOGIST" was commenced, which in all respects, as regards the plates, typography, and literary matter, is not surpassed by any other pictorial gardening periodical. The plate contained in the first number is worth all the money charged for the magazine itself, and illustrates two extraordinary Begonias, introduced by the Messrs. Veitch & Sons, the flowers of which are as large as those of the Christmas Rose, and the plants themselves perfectly hardy. The moderate price of one shilling, at which the magazine is published, brings it within the reach of all who wish to keep informed of the introduction and delineation of the best novelties.

WORK FOR THE WEEK.

KITCHEN GARDEN.

At this season, when there is little cropping to be done, everything should be made clean and neat. All vegetable refuse may be collected into a heap to rot for manure; nothing of this kind should be lost. Vacant ground may be turned up roughly, to be fully exposed to the action of the weather. This is especially necessary in the case of strong soils, in order that the frost may render them more friable. When manure is applied, a little at a time, and as often as an opportunity and the nature of the crops will allow, will be better than when the ground is overloaded with dung. *Peas* and *Beans*, defend forward crops from slugs by quicklime or coal ashes, or strew tender leaves of Cabbages on the ground, and examine them every morning. Early *Radishes*, *Lettuces*, *Herbs*, and *Small Salads* may now be forwarded on slight hotbeds. The earliest crop of *Potatoes* may be potted in 48-sized pots, placed anywhere in the stove till fairly up, and then be removed to a cold vinery to harden. Afterwards turn out the plants in a turf pit, covering with reeds, and placing a little hot dung under them.

FRUIT GARDEN.

Continue to prune any fruit trees if not done already, taking care, however, to keep the spurs short and close, otherwise they soon become long, and give the trees an unsightly appearance. *Strawberries*, it will be well to take some into a cold vinery or Peach house, and place them on the shelves.

FLOWER GARDEN.

If the weather is mild, the planting of shrubs and trees may

be proceeded with, as may also the pruning where pruning is necessary. All the spare ground in the reserve garden, if not already dug, should be laid up in ridges, and where the ground is heavy a good dressing of leaf mould and sand, 2 or 3 inches thick, will improve it much. Take advantage of frosty weather to bring in a quantity of sand, in which to plunge half-hardy plants when hardening-off for the flower garden. Auriculas require great attention just now. If healthy they will withstand intense frost with impunity. Care must be taken to remove decayed leaves, stripping them downwards to avoid wounding the stem. The surface soil should be kept stirred, and the plants be allowed all the air possible, bearing in mind that drip or too much moisture at this season is very injurious. Polyanthus must have all trusses of flowers removed as these appear, if good blooms are to be expected at the proper season. Tulips appearing above ground should be covered on frosty nights with mats or hoops placed across the bed. If sand is put on them it must be white or silver sand; if covered with pit sand impregnated with iron it will have a most deleterious effect on the foliage. Carnations must have all the air possible if they are well established and of a fine glaucous hue; but they require little attention in comparison with those that have been potted late. If in frames, bricks ought to be put at each corner, raising the woodwork at least 4 inches from the ground to secure good ventilation. Itanunculus beds, which ought to have been prepared in the autumn, may have a dressing of old cow manure and decayed leaves forked slightly in preparatory to planting in February. Examine Pink beds, and where the pipings have been raised by the frost or worms they must be carefully fastened. In bad weather labels ought to be made, hand-glasses mended, leaden layer pegs straightened, Carnation sticks made, and similar work carried on.

GREENHOUSE AND CONSERVATORY.

A great step towards the proper management of stove plants in winter was made when those in flower at this season were found to do well enough in a temperature averaging 45° in the conservatory. *Euphorbia jaequiniiflora* is the best stove plant we have in winter, and the flowers are even more brilliant in winter in the conservatory than in the stove. Among the forced flowers the Narcissi, Hyacinths, and early Tulips, with some of the different Roses, are now the most prominent. Sweetbriar is always most welcome in winter, and no place should be without Mignonette in pots or boxes. *Polygala chamaebuxus*, a very dwarf plant, is excellent for forcing, and will keep a long time in flower in any dark corner, where little else would thrive. It requires abundance of water. Frequent failures result from the careless watering of greenhouse plants in winter, not by too much, but the contrary. The best criterion is to have all the soil in the pot of equal dampness throughout, and neither wet nor dry. Keep these and all other plants free from dead leaves and insects, and neatly tied-up to stakes, or trained according to the habit of the plant.

STOVE.

Many of the Orchids are now enjoying a comfortable repose, while others, less fortunate, have to struggle on against our long nights and comparatively dull days. Assist the latter class by giving them as much light as you can, and do not excite them to too rapid growth. Look also over the *Hedychium* now potted under the stages or on shelves, and start a few roots into growth to prolong their season. No plants are more fragrant or more suitable for the conservatory when in flower than *Hedychium maximum*, *coronarium*, and *Gardnerianum*; but the flowering of the last is, unfortunately, of short duration. All sorts of foreign stove seeds, or of any description from abroad, may now be sown with safety. This is the best time to sow seeds of fine *Rhododendrons*, *Azaleas*, and *Kalmias*. If the paths, stages, plants, &c., are kept clean, and the heating apparatus is in good working condition, there will be little necessity for giving much air in dull weather at this season to stove plants at rest.

FORCING FITS.

These are now crowded with Roses, Lilacs both common and Persian, Sweetbriar, Cinerarias, Hyacinths, Tulips, Narcissus, Jonquils, Anne Boleyn Pinks, Gardenias, *Rondeletia speciosa*, *Franseria Hopeana* and *latifolia*, *Acacias*, Chinese and other *Azaleas*, *Pelargoniums*, *Rhododendrons*, *Andromedas*, &c. These may be syringed once a-day and smoked occasionally, and a temperature of from 55° to 65° should be maintained.

PITS AND FRAMES.

Take advantage of the first leisure hour to take stock of the plants for bedding-out in these structures; and if you have not

sufficient of some kinds, introduce a few plants into heat to supply cuttings for propagation. Where there is the advantage of a little heat, a sowing of Ten-week and Intermediate Stocks may be made; and if strong plants of *Clintonia* and *Brachycome* are required for bedding-out, seeds of these may also be sown.—W. KEANE.

DOINGS OF THE LAST WEEK.

The weather has been a hindrance to much of the usual routine of out-door labour, and many workers have been unable to pursue their usual employment. For all, and especially for those frozen-out, it is good that "Christmas times" do come once a-year.

KITCHEN GARDEN.

Wheeling, trenching, collecting ice, and preparing for planting have been the chief work out of doors in the severe weather, little of the weather as yet being sufficiently stormy to render house work necessary, which, therefore, has been kept in abeyance. Fresh successions of Sea-kale, Rhubarb, &c., were placed in the Mushroom house. The Celery was allowed to remain covered-up, and hardly anything in the vegetable way that was coming on and protected received light, except Asparagus, which otherwise would have become very white. The little snow has been a good protection to Cabbages, Broccoli, and Greens in the open garden; no vegetable seems to have suffered as yet. It is advisable to go over early Broccoli, such as Snow's and Grange's, and not only turn over a leaf, but place a little clean hay over the heads that are forming. Our Cauliflowers heading in an earth pit will do good service if we can manage to keep vermin at a distance.

FRUIT GARDEN.

Much the same as in previous weeks, only we gave, in a snowy day, when the glass was covered, a good fumigation to one of our orchard houses, with cut and bruised laurel leaves and twigs. The smoke would enter every cranny where even hot water might miss. Right or wrong, we attributed our freedom from insects last year to this smoking. We do not mind how dense and suffocating the smoke is, provided there is no flare or flame, and the smoke does not become hot. When fairly lighted, therefore, we generally cover the laurel leaves over with damp grass, to prevent anything like flame. These houses are very open, no glazed laps, and therefore smoking would be useless unless the glass was covered, and there is no covering so good or so economical as snow.

We know it is not common to fumigate trees when thus in a state of rest; but it takes little time, and prevention is better than cure. We might have used tobacco but for the price, and we have not yet tried any of that exempt from duty, but mixed with sulphur, as we do not know what quantity of sulphur may be in the mixture. Most likely such a mixture might be used safely for such trees and plants when in a state of rest if the wood were thoroughly ripened, and there had been no movement in the buds, as we have frequently used sulphur alone, covered-up with damp moss, to prevent it flaring; and for empty pits and houses such smoking is beneficial before cleaning and filling them afresh.

As stated, however, in answer to correspondents lately, *burning sulphur* with open flame, or flame smothered as above stated, will kill every green growing plant, and it will kill wood of a deciduous plant when in a state of complete rest, if the wood is not thoroughly ripened. The late Mr. Errington used it, mixed with sawdust, for vineries, &c.; but it should never be used by beginners, unless in empty houses and pits; for if the wood of Vines, even, is not thoroughly ripened, the burning sulphur will seize on every part at all green, and kill as far as it is green. We have had the bark of the young shoots of Peach trees affected by it in spots, when we thought the whole was sufficiently indurated to stand it; and though it did not injure the future swelling of the fruit, these shoots thus spotted we did our best to cut out and replace with fresh in the following season. In answer to "ALINA," then, we say, first, that we have not yet tried the Government-permitted tobacco mixture; secondly, that we should be chary of using it in houses at rest, unless where the wood of Vines was as hard and firm as the shoots of Oak trees; and thirdly, that for all green-leaved growing plants its use as smoke by burning would be ruinous, and that in proportion to the sulphur contained in it.

Were we much troubled with insects we would be inclined to try the strong tobacco water, advertised as manufactured from

untaxed tobacco. If sure that there was nothing in that but tobacco we should know what we were about, and we could make a smoking material from it, most likely much more cheaply than we could cultivate and preserve home-grown tobacco, for if not properly sweated and cured it is of little use for the destruction of insects. The worst that can be said against tobacco paper, much of which is very good, is that not knowing what it is made of, we are always somewhat uncertain as to "how" to use it. We have seen smokers from tobacco paper kill every insect and not injure a single leaf. We have seen it used with equal care, and if it did not kill the insects, it nearly destroyed the plants; hence the importance of prevention rather than cure. In all smokers of green growing plants two conditions are essential to safety and success; The leaves and stems of the plants should be dry, and the air confined also pretty dry, and the smoke must be cool. Hot tobacco smoke, however pure the tobacco, will injure any growing plant, and just in proportion to the heat and the vigour of the plant. As frequently observed, when plants are covered with insects it is lost labour in general for that time to waste tobacco on them. A smoking box is extremely useful and economical in most places. A few plants may thus be cleared as effectually by means of a pinch of tobacco as would have required ounces or pounds in large houses.

Where the spade would penetrate the ground—which it would easily do where the ground was carpeted with rough grass—no time could be better for collecting the soil for composts, border-making, and similar purposes. We shall be more particular in allowing our fruit trees to have the soil about them mostly, if not altogether, to themselves, when we become thoroughly convinced that many trees in small compass will yield a better and more interesting return than a few large trees, for which ladders and other appliances must be obtained to reach and gather the produce. As nothing can be produced beneath these trees, we trust the time is at hand when, if kept, they will be kept to themselves in the orchard, with long grass for the fruit to fall on, and be completely banished from the kitchen garden. Even dwarf fruit trees we would prefer to be planted in quarters or groups by themselves, and then they could be easily protected from frosts and their many enemies.

ORNAMENTAL DEPARTMENT.

Moving plants, potting, watering, cleaning, and placing soil over furnaces and in stoveholes to warm and mellow, formed our principal work, in order to be ready for many purposes as the weather improves; confining the potting and top-dressing as far as possible to the houses or the sheds adjacent, without taking the plants out of doors, as in general the wind was very cold for the degree of cold indicated by the thermometer.

Climbers and Twiners.—The dull weather has given us an opportunity for regulating these. A considerable uncertainty exists among amateurs as to cutting and pruning. In the great proportion of climbers the flowers are produced on young shoots of the current season's growth, as *Passifloras*, *Tecomas*, *Stephanotis*, and *Mandevillas*. In young plants, therefore, the aim should be to obtain one or more vigorous shoots, and to have these well ripened, and then by merely shortening these shoots a little, so as to remove the greenest part, the buds behind will break into shoots, and be flowering shoots just in proportion as the primary shoot was well ripened. Such climbers may therefore be treated as Vines bearing on the long-rod system, dispensing with all the small shoots and flowering part, and supplying with fresh rods every season. This, however, involves much trouble, and is chiefly useful to be followed until the plant has filled its place, and then it will be more easily managed on the one-main-shoot system—or rather principle—like a spurred Vine. Some of the finest *Passifloras* we ever saw were run as a main stem all the length of a house, and were thickly studded with flowering shoots hanging down all the way. These were cut back in winter, when more light was required, generally at twice, with an interval between the two operations, leaving only a bud or two at the base, next the main stem. Next spring the flowering shoots came again from these buds, just as in the case of the Vine, and the pruning and treatment were thus reduced to the least amount of trouble and supervision. In all cases free-flowering shoots can only be obtained from well-ripened wood.—R. F.

TRADE CATALOGUES RECEIVED.

James Carter & Co., 237, 238, and 261, High Holborn, London, W.C.—*Gardeners' and Farmer's Trade-Memoir*. Part I.—

Flower Seeds, Plants, and Bulbs. Part II.—Vegetable and Agricultural Seeds.

E. & T. Lant, 7, Easy Row, Broad Street, Birmingham.—
Descriptive Catalogue of Agricultural, Flower, and Vegetable Seeds.

COVENT GARDEN MARKET.—JANUARY 8.

ALTHOUGH the holidays may be considered as terminated, there is no revival of business, and the slight advance of last week has been barely maintained. French importations comprise Lettuces, Endive, and Asparagus.

TO CORRESPONDENTS.

BOOKS (*An Inquirer*).—A volume with numerous plans of gardens, small and large, will be published at this office early in this year.

RAIN WATER FROM ASPHALTED ROOF (*G. E.*).—We would not like, for watering plants, the water that came from an asphalt roof for at least six months after it was laid down. After that, if the surface of the asphalt was roughened with sand or gravel, our observation would lead to the conclusion that the water would be pure enough.

VINES IN AN INTERMEDIATE HOUSE (*A Subscriber*).—It will do no harm to Vines to be kept in a house all the winter where fire heat is used, provided that fire heat does not raise the temperature of the house more than from 40° to 45°. In an intermediate house, where from 45° to 55° of temperature is maintained, the Vines should be brought to the front of the house, and there managed so as to secure a lower temperature whilst in a state of rest. If the Vines, so healthy-looking, showed no fruit, we fear that merely grafting them would be of no use, unless they were some kinds of foreign origin that do not thrive under glass. We suspect your Vine wood has not been sufficiently ripened.

STRAWBERRY—VINERY (*Half-pay*).—For a sure and plentiful-bearing Strawberry, there is none to beat Keen's Seedling. Six Vines are quite enough for your 15-foot-long house. Your Vines are weak; but if they have commenced rooting pretty well, and if the kinds are suitable, we would try them another year, cutting them as far back as would be convenient, just a little above a bud, and allowing only one shoot to come next season, fastening it carefully as it grows. As you describe the young growth to have made a head like a Currant tree, we presume from this that the roots have made some progress, and that therefore the Vine will come stronger next season when the strength is thrown into one shoot. As you say you know nothing of pruning, we have given the above advice to cut down to the lowest convenient part of last year's wood, take only one shoot from a Vine, and train that without stopping it until it almost extends the length of the roof. As it grows, subsidiary shoots will come from each joint; stop these when two leaves appear, and allow them to remain until September, then cut them all off, and stop the point of the main shoot. Keep the house dry and warm to encourage the hardening of the wood, and next winter, or by this time, prune back your Vines, leaving from 1 to 2 or more feet, according to strength. If strong, the Vines may bear from one to two or three bunches in the following season. The leading shoot must be grown and treated as last season, and the shoots that come from the buds beneath the top one should be stopped a joint or two beyond the fruit, and, at any rate, at the fifth or sixth joint. By that time, if you are not well acquainted with them, we will enter into all the details of pruning, according to the system adopted. If you prefer stronger Vines to plant, you might take up the present ones and pot them; but the new Vines you would also have to cut back, and they might not do much better than those you have, if the roots are in good condition, as, in this respect, they will have an advantage over fresh-planted ones now. If so weak as you say, you could obtain nothing from them in the way of fruit next summer. After potting you would have to cut them down to the surface of the soil, and grow a shoot or shoots from them, which, if well ripened and well grown, would fruit in another year. You do not tell us where the 2-foot border in this 15-foot-long house is placed. If against the back wall a Peach

tree might certainly be planted there, and all the better if you could raise and place good soil under the flagstone; but unless you had a large tree that would fruit quickly, it would be of little use planting one or two young trees, as with six Vines up the glass in front, the shade would be so dense that nothing would thrive well under it. If you wished variety, instead of planting out, we would have Peaches and Nectarines, and even a Fig tree or two in pots, if you like Figs. They would come in early, be set before the Vines wanted much heat, and then when the fruit was gathered the plants could be set out of doors to obtain all the light possible in the autumn. You would find much to suit you in the "Vine Manual," which may be had from our office, free by post, for thirty-two postage stamps. We have forgotten to say that if, as we suppose, your Vine roots are out of doors, you should protect them from frost and much wet in winter.

HEATING A TANK (*A Novice*).—See what is said to-day in answer to "HALF-PAY" as to heating a small tank from the pipes in a hothouse. Your tank is smaller, 6 feet by 2½ feet, but 6 inches deep—just double what is necessary. You do not tell us how you heat your greenhouse, and, of course, you could heat your tank from a boiler heated by fuel, as you say; but it seems a large amount of work to have a boiler for such a small affair, though, in our opinion, if the tank is secure, it matters but little whether you have water in it, or pipes passing through water. If your house is heated from a boiler you could do as "HALF-PAY" has done, take a pipe from the pipes in the house. There is this objection to the plan, that you cannot have heat in the tank without heating the house, whilst you might want heat there when no artificial heat was needed in the house. Under such circumstances small propagating tanks or cases in a greenhouse or living room are best heated separately by gas, or a lamp, the heat passing through the water in pipes; or, simpler still, by having the tank about 2 inches deep, a plug or tap at one end, and an opening or funnel at the other, and removing cold water and replenishing with hot as necessary. A supply of hot water by means of the garden pail once in twenty-four hours, and twice in very cold weather, if hot water can be easily had, would cost less trouble than having anything in the way of a separate boiler and means of heating. We have found water, when surrounded outside with wool, keep warm frequently for thirty hours.

TANK NOT HEATING (*W. A. O.*).—If you had shut-in 6 feet of your flow pipe you might have had enough of heat for your purpose. We understand exactly about the tank you have cast, which is 6 feet long, 4 feet wide, and 3 inches deep, and which you have connected with the flow and return pipes in the house by means of a 1-inch lead pipe; but we cannot be sure why, though the main pipes in the house are so hot you can scarcely touch them, you have little heat in the tank, unless it is that the tank is not placed right as respects its level with the flow pipe. There will be a circulation if the tank is on the level of the top pipe; but if other arrangements will permit of it, the hot water will circulate much better if the bottom of the tank is at least as high as the top of the flow pipe. That elevation secured, we would let the small pipe from the flow enter at one end, and the return be connected with the return at the other end of the tank. If these connecting pipes are straight, without bends, it will be all plain sailing, and work they must. We lay all the more stress on this fact, because in several cases in our own practice, when connecting such a tank to a higher level, with a flow 4-inch pipe beneath it, and to suit convenience we had bent the small connecting pipe a little in form of the letter S, we found at times air accumulated at the bends, and impeding the circulation. A small air pipe inserted in the bend, rising above the level of the tank, settled the matter, and if not so soon as we wished, we had only to blow down to obtain a very rapid circulation of the water, so that the water in the tank and the water in the pipes was soon at the same heat. We say this much as respects level, because the other day a tank, formed at some expense, could not be heated, as it was below the level of the flow pipe, from which the heat was to be borrowed.

LILIUM ACRATUM (*Idem*).—The numerous small bulbs left after the decay of the old bulbs, are something to be thankful for. Your treatment seems to have been quite correct. Too much damp after the bulb is ripe will sometimes accelerate such decay, and cause the bulb in natural defence to put forth its last energies in a brood of young bulbs.

MANDARIN ORANGE (*Idem*).—We would grow it in good brown fibry loam, with a fourth part of rotten dunghy, fibry heath mould, and a little silver sand. We would merely stop the strong shoots, and if the others are very thick thin them a little; but in most cases, if the shoots are regular, and light and air can reach them, they will need little to be done to them.

POTTED RHODODENDRONS (*Idem*).—They should be encouraged to grow freely when done flowering, and until the buds are set for blooming, and then when potting is needed they should be repotted, giving small shifts, and so that the new soil may be well filled with roots before winter.

PRUNING MANDEVILLA SCATEOLENS (*Idem*).—The straggling shoots may be pruned in now. If used to it, the plant may be pruned like a Vine on the spur system. If not used to it, and you have some good long shoots, leave them to break all over, like a Vine on the rod system. See "Doings of the Last Week."

VARIOUS (*A Subscriber from the First*).—"The Florist and Pomologist" begins a new volume this month—January. You might grow a Royal Ascending or a Black Hamburgh Vine in your narrow cold pit; but you would not do so well with the Alicante. There are not many of the small gardens given in the "Horticultural Directory," unless distinguished for something particular. The number given will, no doubt, be increased every year; but to give every garden would require a very large volume, and then few would care about it.

VENTILATING AN ORCHARD HOUSE (*A Subscriber*).—For an orchard house, 36-feet in length by 24 feet in width, span-roofed, with side ventilation, an opening at each end beneath the apex would be enough. For a greenhouse or forcing house, the roof ventilation would be best secured by having a double ridge board, with a space of 9 to 12 inches between the boards for wooden ventilators hung on pivots, and with that space covered with a cowl of boards outside to let in the air and keep out the wet. These ventilators will be easily managed from the path in the centre of the house. If the path is not in the middle, then it would be better to have two openings to slide, besides the openings at the ends.

SPOTS ON TRICOLORED PELARGONIUMS (*St. Dennis*).—They probably have been kept too cold and too damp. More heat, more ventilation, and

less water will, probably, restore them. Comtesse de Jaucourt is a very superior loss.

NEW ZEALAND LAUREL (G. N.).—It is the *Corynocarpus levigatus*, and is thus mentioned in the "Treasury of Botany." The tree, according to Dr. Bennett, is valued in New Zealand for the sake of its fruit and seeds; the former is of the size of a Plum, pulpy in the interior and sweet. The seeds are used in times of scarcity, and contain a tasteless farinaceous substance. The raw seeds, however, are poisonous, and produce spasmodic pains, giddiness, and partial paralysis; to obviate which effects they are steamed for twenty-four hours, and then either buried in the ground, or allowed to soak in water for some days.

TYING-IN STRAGGLING CYPRUS TREES (J. T.).—We should try to tie-in the branches displaced by the snow storms of the winters of 1865 and 1866. We would use strongtarred rope, equal in thickness to the branches to be tied; and if the tying be done effectually the branches will, probably, recover their erect and proper position in the course of a few years. The tarred rope will last a long time, but it may be necessary to renew it in order to keep the straggling branches in their proper position. If you can remove them without making gaps, that will be the most certain mode of securing the symmetrical character of the trees; but we fear you cannot do so without disfiguring the latter for a long time. It is well to do without tying if you can.

VALLOTA PURPUREA POTTING (J. Luck).—You may pot it if necessary, but it is well not to overpot, as it flowers more freely when its roots are confined than when overpotted. The drainage should be good, and therefore the plant should be turned out of its pot and the drainage made good, placing in a larger pot if the roots are very much matted. Loosen the ball, and remove as much of the old soil as possible, but be careful not to injure the roots. If the plant has very few roots shake away all the old soil, and place it in a pot twice the diameter of the bulb, for that size is sufficient. If you have more than one bulb in a pot, the pot may be larger in proportion. The book you name is a good one, but not the best.

CROCUSES EATEN BY MICE (J. F. C.).—We think that the mice eating the Crocuses in the beds and leaving those in pots untouched, is attributable to the former not being planted so deeply as the latter, and being, therefore, more easily attacked. When the mice have devoured those in the beds they will find out those planted more deeply. We are not aware that mice devour the foliage; but they will, probably, attack the bulbs in pots as soon as it appears above ground, if not before. You may trap them with a figure-1 trap, baited with the half of a Crocus bulb, or a whole small one.

MEALY BUG ON VINES (J. Z.).—We would remove all the loose bark, especially that on the spurs, and it may be done quite down to the wood. Under the old bark you will find the insects in greater numbers than you supposed. There they lurk until forcing is commenced. Any dressing of the Vines will be of little or no avail, because it cannot reach the bugs unless the loose bark be taken off. After clearing the Vines well of loose bark you may wash them thoroughly with water at 140°, and afterwards paint them with a solution of Gishurst Compound at the rate of 8 ozs. to the gallon of water. This strength will not injure the buds if you only apply it before they begin to swell. The Vines should be washed with a paint brush, and the solution of Gishurst applied with the same, rubbing it well into every crevice.

CINERARIAS LOSING THEIR FLOWER STEMS (Idem).—We are unable to assign a reason for the stems dying off. Probably their being eaten by some insect is a cause for it; but we are not able to form an opinion with so little knowledge of the treatment the plants have received. There must be some cause of the decay at the surface of the soil. Appleby's "Orchid Manual" will suit you. You can have it free by post from our office by enclosing thirty-two stamps with your address.

GARDENERS' EXAMINATIONS (Idem).—Write to Mr. Richards, Assistant Secretary, Royal Horticultural Society's Garden, South Kensington, London, W.

ORCHIDS (J. Query).—Of the list of Orchids sent the following would succeed in a greenhouse with a temperature of 50° in winter, a corresponding heat being given during the summer, with a moderately close and humid atmosphere: *Oncidium ornithorhynchum*, *O. leucociliatum*, *O. crispum*, and *O. pulvinatum*; *Odontoglossum grande*, *O. citrosum*, *O. pulchellum*, and *O. maculatum*; *Trichopilia tortilis*; *Epidendrum vitellinum*, *E. aromaticum*, and *E. macrochilum album*; *Brassavola glauca*; *Cattleya citrina*; *Lælia albida*, *L. acuminata*, and *L. furfuracea*; *Lycaste*

Skinneri, and *L. aromatica*; *Sophronis cernua*; *Acineta Humboldtii* and *Barkeria Lindleyana*. All these we have grown in a cool house, 5° lower than the temperature you name. The others named we have tried to some extent, but they do not succeed. They require a stove temperature.

POTTING CYCLAMENS (Calcevia).—Seedling bulbs of Cyclamens may be potted at this season, especially if of the persicum race, and they are not expected to bloom before February. It is a good practice to adopt with growing, but not blooming, plants of Cyclamen persicum, especially when a late bloom and extra-sized plants are required, the potted being carefully performed without disturbing the ball. Other Cyclamens do best if placed in their blooming pots before, or when they are beginning to grow. Disturbing them in any way when showing for bloom is bad, as it more or less disarranges the foliage.

SELAGINELLA OFFSETS (Idem).—You could not have adopted a better plan, and there is every reason to conclude they will do well. Do not keep the soil very wet, but let it be moist, and admit a little air every day, but without reducing the moisture and temperature so much as to cause them to flag. When they become rooted they will succeed in a night temperature of 50°.

SELECT CAMELLIAS (W. G. G.).—Marie Morren, Queen of Beauties, Story, Rubens, Fimbriata, Alba plena, Bénédict, Mathotiana, Jenny Lind, Mrs. Cope, Giovanni Santarelli, and Carlotta Papudoff. We are not aware that grafting Camellias on Orange and Lemon stocks has been practised, and we do not think they would succeed. It is a matter for experiment.

VINE FIBRES DECAYED (J. R. B.).—The roots sent have many of the fibres quite dead, and, we think, owing to the unsuitable materials of which the border is composed, which cannot be otherwise than too close and retentive of moisture. Being principally clay, it has settled into a close wet mass, which, instead of improving, must get worse, there being nothing to keep it open but the lime rubbish and bones. We cannot understand how any one can be so stupid as to endeavour to drain a Vine border by putting rubble over the bottom, and then concreting upon the rubble. How is the water to pass away? It is only making a receptacle for water to lodge in. The concrete ought to have been at the bottom of the border to prevent the roots going down, and then the rubble 9 inches thick, with a drain at the lowest point to carry off any accumulation of water; but as it is, the water cannot pass through the concrete into the rubble and to the drain. The concrete where it is, is worse than if the border had not been drained and no rubble put in. Clay is a bad material to form a Vine border of. A little marl may do good; but clay should be avoided. Good turf, cut 2½ or 3 inches thick from a pasture where the soil is a light rather than heavy loam, is best for Vine borders. We do not wonder at the fibres decaying; it is only what might be looked for.

CLIMBERS FOR STOVE (Idem).—*Allamanda grandiflora*, A. Schottii, *Thunbergia Harrisii*, *Manettia micans*, *Hoya carnea*, *Clerodendron Thomsonii*, *Bignonia grandiflora*, *Combretum purpureum*, *Passiflora quadrangularis*, and *Stephanotis floribunda*. The wall must not be shaded by plants or by climbers on the roof, otherwise they will not succeed.

APPLES FOR ESPALIERS (A. F. P.).—Ashmead's Kernel, Cockle Pippin, Cornish Gilliflower, Cox's Orange Pippin, Downton Pippin, Kerry Pippin, Margil, Nonpareil, Pitmaston Nonpareil, Scarlet Nonpareil, Sturmer Pippin, and Jonanetting.

NAMES OF FRUIT (J. D.).—Apples: 1, Colonel Vaughan's; 4, Court Pendu-Plat; 5, Lemon Pippin; 6, Winter Greening; 8, Winter Pearmain, or Duck's-bill; 9, Braddick's Nonpareil. (*J. W. juv.*)—1, Spencer's Seedling, is a local variety; 2, Minchall Crab; 3, Nelson Codlin. (*J. F. Lombard, Dublin*).—Your Apple is *Cambusnethan Pippin*.

NAMES OF PLANTS (T. Brown).—*Gnaphalium arenaria*. (*S.*)—1, *Euphorbia apocynifolia* (?); 2, *Euphorbia jacquiniiflora*; 3, The leaf appears to be that of *Commelyna* or *Aneilema*. (*R. F.*)—1, *Adiantum formosum*; 2, *Aspidium aculeatum*; 3, *Cornella pentaphylla*; 4, *Ageratum conyzoides*; 5, *Acacia cæsia*, var. (*J. T.*)—1, *Eranthemum sanguinolentum*; 2, *Chamaeranthemum Williamsii*, var. (*T. H.*)—1, *Justicia (Bellia) ussurgens*; 2, *Acanthaceae*, but not possible to determine without a flower. (*Jas. Luck*)—1, 2, *Aspidium aculeatum*, var.; 3, *Asplenium Filix-femina*, var.; 4, *Aspidium aculeatum*, var.; 5, *Lastrea Filix-mas*; 6, *Aspidium leucitis*. N.B.—Several of these are barren and in a young state, so that the variety cannot be determined.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending January 7th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

SOMERSET COUNTY POULTRY SHOW.

It is very rarely indeed that we have to record the holding of so excellent a first Show of Poultry and Pigeons as that which took place

on the 1st, 2nd, and 3rd of January at Weston-super-Mare. The general arrangements, however, betrayed great inexperience in the management of a public Poultry Show, and, from the fact of the prize list reaching our reporter at so late an hour, we can do little more than simply record the returns, though we have corrected the list, as printed by the Weston-super-Mare Committee, by the award book of one of the Judges. We deeply regret there should have been any hitch of the kind, as the Show was unquestionably one of first-rate

character, and we most sincerely hope the experience of another year may prevent the like again occurring.

SPANISH.—First, H. Lane, Ashley Road, Bristol. Second, E. Jones, Clifton, Bristol. Third, W. Bone, Park Street, Bristol. Highly Commended, A. Heath, Calne. *Chickens*.—First and Cup, also the ten guinea Cup for the best pen of Poultry in the Exhibition, F. James. Second, J. Newton, Silsden, Leeds. Third, H. Lane. Highly Commended, Hon. Miss Douglas Pennant, Penrhyn Castle, Bangor; A. Heath; T. Bainfield, Braddon Hill, Bristol. Commended, E. Jones. *Cock*.—First and Second, Withheld. Third, W. Smith, Weston-super-Mare. *Cockerel*.—First and Cup for best single Cock or Cockerel in the Exhibition, E. Jones. Second and Third, A. Jones, Stapleton, Bristol. Commended, A. Jones; Hon. Miss Douglas Pennant; T. Bainfield.

DORKINGS (Coloured).—First, D. C. Campbell, M.D., Brentwood. Second, L. Patton, Comestrowe House, Taunton. Third, Mrs. F. S. Arkwright, Etwell Hall, Derby. *Chickens*.—First, Cup, and Second, Mrs. F. S. Arkwright. Third, D. C. Campbell, M.D. Highly Commended, L. Patton; C. Cork, New Shoreham; Miss A. Wilcox, Nailsea Court, Bristol. Commended, Lieut.-Col. H. B. Lane, Bracknell.

DORKINGS (White).—First, Rev. G. F. Hodson, North Petherton. Second, Mrs. Hartwell, Penleaz, Bridgewater. Third, T. P. Edwards, Lyndhurst, Hants.

DORKINGS (Any variety).—*Cock*.—First, Withheld. Second, L. Patton. Third, H. Walker, Shenfield, Brentwood. *Cockerel*.—First, Lady M. Macdonald, Woolver, Liphook. Second and Third, L. Patton.

COCHINS (Cinnamon and Buff).—First and Cup, H. Mapplebeck, Woodfield, Moseley, Birmingham. Second, W. A. Taylor, Turner Street, Manchester. Third, R. White, Broadhall Park, Sheffield. Highly Commended, J. H. Dawes, Moseley Hall, Birmingham.

COCHINS (Partridge and Brown).—First, E. Tadmam, Whitechurch, Salop (Partridge). Second, T. M. Derry, Geduey, Lincoln. Third, A. O. Worthington, Newton Park, Burton-on-Trent.

COCHINS (White).—First and Second, R. Chase, Balsall Heath Birmingham. Third, F. J. Shortis, Flax Bourton, Somersetshire.

COCHINS (Any variety).—First and Second, H. Mapplebeck (Buff). Third, E. Tadmam (Partridge). Highly Commended, W. A. Taylor; J. H. Dawes (Buff). Commended, Hon. Miss Douglas Pennant (Buff); A. F. Worthington (White). *Cock*.—First, R. White (Buff). Second, Withheld. Third, C. J. Lambert, Kingswood, Bristol (Partridge). *Cockerel*.—First, Mrs. H. Dean, Upton, Southam, Warwick (White). Second, Miss J. Milward, Newton St. Loe, Bristol. Third, H. Mapplebeck (Buff).

BRAMA POOTRA (Dark).—First and Cup, R. W. Boyle, Galtrim House, Bray, Co. Wicklow. Second, H. Lucy, Hebdon Bridge. Third, Mrs. A. Hurt. Highly Commended, F. Crook, Forest Hill, London. *Chickens*.—First, Lieut.-Col. H. B. Lane. Second, R. W. Boyle. Third, Mrs. A. Hurt, Alderwasley, Derby. Commended, Miss H. Attye, Ingon Grange, Stratford-on-Avon; L. Wright, Southwell Street, Bristol.

BRAMA POOTRA (Light).—First, H. Dowsett, Pleshey, Chelmsford. Second, Miss Harvey, Salisbury, Southampton. Third, H. Lucy. *Chickens*.—First and Third, J. Pares, Postford, Guildford. Second, A. Herbert, Eglau. Highly Commended, A. Herbert; H. M. Maynard, Holmwood, Isle of Wight. Commended, A. Herbert.

BRAMA POOTRA (Any variety).—*Cock*.—First, R. W. Boyle. Second, J. Hinton, Hinton, near Bath. Third, S. Felgate, St. Margaret's, Ipswich. *Cockerel*.—First, R. W. Boyle. Second, C. Crook (Dark). Third, J. K. Fowler, Aylesbury. Highly Commended, L. Wright.

GAME (Black-breasted and other Red).—First and Cup, J. Fletcher, Stoneclogh, Manchester (Black Red). Second, E. Aykroyd, Bradford (Red). Third, W. Boyes, Beverley (Red). Highly Commended, Rev. G. S. Cruwys, Cruwys Morbard Court, Tiverton; S. Dupe, Evercreech, Bath; Rev. J. Mellor, Colwick Rectory, Notts (Black Red).

GAME (Duckings and other Greys and Blues).—First, J. Fletcher (Duckings). Second, W. Dale, Weston-super-Mare. Third, S. Dupe. Commended, A. K. Briggs, Bradford.

GAME (Any other variety).—First, J. Fletcher (Piles). Second, S. Matthews, Stowmarket (Piles). Third, J. Vincent, Bromyard (Black).

GAME (Any variety).—*Chickens*.—First, J. Fletcher (Black Red). Second, A. M. Forde, Castle Cary. Third, W. Slagg, Netheravon, Pewsey (Black Red). Highly Commended, J. Fletcher (Black Red); S. Matthews (Black Red). Commended, W. W. Pyne, South Lancing, Sussex. *Hen*.—First, J. H. Williams, Spring Bank, Welshpool (Black Red). Second, W. H. Slagg (Black Red). Third, S. Dupe. Highly Commended, E. Aykroyd; J. Vincent; G. Clements, Birmingham. *Cock*.—First, J. Fletcher (Black Red). Second, Rev. J. W. Mellor. Third, W. H. Slagg. *Cockerel*.—First, A. K. Briggs. Second and Third, G. Clements.

HAMBURGS (Golden-pencilled).—First, H. Beldon, Gt. Stock, Bingley. Second, F. Pittis, Newport, Isle of Wight. Third, Mrs. Farquharson, Wyck Hall, Stow-in-the-wood. Highly Commended, H. Pickles, jun., Earby, Skipton.

HAMBURGS (Silver-pencilled).—First, H. Beldon. Second, J. Preston, Ollerton, Bradford. Third, W. Bairstow, Fearncliffe, Bingley.

HAMBURGS (Golden-spangled).—First and Cup, H. Beldon. Second, T. Wrigley. Third, W. Hyde, Hurst, Ashton-under-Lyne. Highly Commended, J. Ogden, Hollingwood, Manchester; T. Walker, jun., Denton, Manchester; G. Walters, Worcester. Commended, H. Pickles.

HAMBURGS (Silver-spangled).—First, H. Beldon. Second, H. Pickles. Third, G. Walters.

HAMBURGS (Black).—First and Second, T. Wrigley, jun., Tonge, Middleton, Manchester. Third, H. Beldon. Highly Commended, G. Lingard, Snow Hill, Birmingham.

HAMBURGS (Any variety).—*Cock*.—First, J. Fielding, Newchurch, near Manchester (Silver-spangled). Second, H. Beldon. Third, F. Pittis. Highly Commended, W. A. Hyde (Golden-spangled).

POLANDS (White-crested Black).—First and Second, T. P. Edwards. Third, P. Unsworth, Loughton, Newton-le-Willows. Highly Commended, H. M. Maynard.

POLANDS (Gold or Silver).—First, H. Beldon. Second, J. Hinton. Third, P. Unsworth.

POLANDS (Any variety).—*Cock*.—First, H. Beldon. Second, J. Hinton (Silver).

FRENCH (Any variety).—First, Col. Stuart Wortley, Grove End Road, London (French). Second, F. H. Wyndham, Ufford Cottage, Salisbury (Crested Grey). Third, H. M. Maynard, Hordans. *Cock*.—First and Second, Col. Stuart Wortley (French). Third, Rev. N. V. Kidley, Newbury. Highly Commended, J. K. Fowler (Grey Cuck).

ANY OTHER DISTINCT VARIETY.—First, R. Loft, Woodmansey, Beverley;

Rev. A. G. Brooke, Ruyton XI Towns, Salop (Malay). Second, J. R. Jessop, Hull (Negroes); H. J. Godfrey, Hammersmith (Black Shanghaes). Third, F. Pittis; H. Leworthy, Newport, Barnstable (White Minorca). Fourth, Col. Stuart Wortley (Frizzled Japanese); Miss S. H. Northcote, Upton Pynes, Exeter (White Spanish); Highly Commended, S. A. Wyllie, East Moulsey, Surrey (Japanese); J. K. Fowler (Japanese Silkies); Mrs. A. Tuckett, Shirehampton, Bristol. Commended, Mrs. E. Llewellyn, Colman, Glamorganshire; Mrs. H. Dean (Cuckoo Dorking); J. Hinton (Malay); W. P. Hadden, West Town, Bristol; H. Leworthy (Anconas).

GAME BANTAMS (Black or Brown Reds).—First, Rev. A. K. Cornwall, Bencombe, Dursley, Gloucestershire (Black Reds). Second, O. Drewry, M.D., Walsall. Third, H. Shumack, Southwell, Notts. Highly Commended, Rev. W. J. Mellor (Black Reds); J. Crossland, jun., Wakefield; J. W. Kellaway, Merston, Isle of Wight. Commended, J. J. Cousins, Allerton Park, Leeds.

GAME BANTAMS (Duckwing, or any other variety).—First, F. Pittis (Duckwing). Second, H. Shumack (Game). Third, F. R. Prideaux, Bridgewater (Duckwing). Highly Commended, H. Lee, Appuldurcombe, Isle of Wight (Piles).

BANTAMS (Gold or Silver Sebright).—First, Rev. G. F. Hodson (Sebright). Second, Third, and Highly Commended, Rev. G. S. Cruwys (Sebright).

BANTAMS (Black, White, or any other variety).—First and Highly Commended, Messrs. Tonkin & Turkey, Bristol (Black). Second, H. M. Maynard. Third, Rev. P. W. Story, Churwellton House, near Daventry (White-fetched-legged). Commended, Rev. G. S. Cruwys (Black and White).

BANTAMS (Any variety).—*Cock*.—First, Rev. W. J. Mellor. Second, Countess of Ailesford, The Bury, Leamington Spa (Japanese). Third, W. Dale, Weston-super-Mare (Black Red).

ANY VARIETY OF CROSS-BRED For Cottagers only. —First and Third, J. Cox, Berrington, near Bristol (Dorking). Second, G. D. Whereat, Weston-super-Mare (Spanish Game).

DUCKS (Ayle-bury).—First and Second, H. Jones, Dinton, Aylesbury. Third, J. K. Fowler, highly Commended, W. Pares, Ockbrook, near Derby. Lieut.-Col. H. B. Lane.

The Judge of Poultry and Pigeons was Edward Hewitt, Esq., of Sparkbrook, near Birmingham; and Mr. Baker, of Cambridge, awarded the prizes for large birds.

SUNDERLAND POULTRY SHOW.

(From a Correspondent.)

THIS Show was held January 1st, in the Central Hall, John Street, Sunderland. The arrangements were very good, and reflected great credit on Mr. Toft, the Hon. Sec., and the Committee of Management. *Bantams* formed the principal feature, and the show of these was very good indeed. Black Reds had the palm, Duckwings running them very closely. We also noticed a very good pen or two of Sebrights. The first-prize pen of Game Bantams, although suffering from cold, were most beautiful birds. The first-prize single Game hen, a Brown Red, was very excellent. Blacks and Whites were a fair show.

Large birds formed a moderate show as to numbers, but the quality was in most cases of a high order, *Poualms* and *Dorplings* being the best. Altogether the Show was a decided success.

Mr. Hodgson, of Darlington; and Mr. Sum, of West Cranlington, were the Judges. The following is the prize list:—

BANTAMS (Black Reds, for Club Members only)—First and Second, C. Grimshaw. Third, J. Clark.

BANTAMS (Duckwings)—First and Third, J. Barrill. Second, C. Grimshaw.

BANTAMS (Piles and White)—First, C. Grimshaw. Second, J. Muirhead. Third, T. Toft.

GAME BANTAM—Cock—First, D. Hunter. Second, W. Dixon. Third, T. Toft. *Hen*—First, A. Bugden. Second, C. Grimshaw. Third, J. Muirhead.

BANTAMS (Sebrights)—First, Messrs. Scott & Ackroyd. Second, T. Toft.

BANTAMS (Black and White, Rose-combed)—First and Third, W. Dixon. Second, J. Muirhead. *Hen*—First, J. Clark. Second, W. Dixon. Third, Messrs. Scott & Ackroyd.

ANY VARIETY—Old Cocks—First, W. Dixon. Second, J. Clark. Third, Messrs. Scott & Ackroyd. *Old Hens*—First, A. Bugden. Second, J. Mullens. Third, J. Muirhead.

GAME BANTAMS (Open to all English)—First, R. Gonll. Second, A. Bugden. Third, Messrs. Scott & Ackroyd.

LARGE BREEDS.

GAME (Black Reds)—First, Second, and Third, J. T. French.

GAME (Duckwings)—Prize, J. Mullens.

GAME—Cock—First, J. Black. Second, J. T. French. *Hen*—First, J. Black. Second, G. Allen. Third, G. Carrick.

HAMBURGH (Pencilled)—First and Second, H. Whitfield Hellen.

POLISH—First, G. Allen. Second, J. Clark. Third, T. Hunter.

COCHINS—Prize, D. Rutter.

DORRINGS—First, D. Rutter. Second, G. Grimshaw. Third, J. Mullens.

ANY OTHER VARIETY.—Prize, T. Toft. (These were very large birds, a cross between Dorking and Brahmas.) *Cock*.—First, D. Rutter. Second, C. Grimshaw. *Hen*.—First, J. Clark. Second, D. Rutter.
DUCKS.—First, Second, and Third, J. Black.

TUMBLERS (Short-faced).—First and Second, R. Fulton. Third, J. Hawley.

TUMBLERS (Any other variety).—First, J. Sharp. Second, J. Hawley. Third, A. Morrison, Glasgow.

CARRIERS.—First and Second, J. Hawley. Third, R. Wardrop.

FANTAILS.—First, J. Sharp. Second, G. White, jun., Ladyburn, Paisley. Third, W. Crawford, Beith.

JACOBINS.—First, J. Hawley. Second, R. Fulton. Third, J. R. Rennards, Helensburgh.

NUNS.—First, R. Davidson, Jedburgh. Second, R. Paterson, Melrose. Third, W. R. Park.

TURBITS.—First, W. R. Park. Second, J. R. Rennards. Third, J. Fielding, jun., Rochdale.

PIGEONS (Common).—First and Third, J. Hawley. Second, J. Glasgow.

ANY OTHER DISTINCT BREED.—First, Second, and Third, J. Fielding.

POUTERS (Any colour).—Medal, J. Sharp (Blacks).

ANY VARIETY (Pouters excluded).—Medal, J. Hawley.

CANARIES.

CLEAN.—First, J. Mair, Kilmarnock. Second, T. Echanan, Glasgow. Third, A. Kelly, Paisley.

YELLOW—*Cock*.—First, R. Houston, Kilbirnie. Second, J. Graham, Kilmarlock. Third, A. Kelly. Fourth, W. McLeod, Glasgow. *Hens*.—First and Third, J. Muir, Kilmarlock. Second, R. Turnbull, Glasgow. Fourth, W. Weir, Paisley.

BUFF.—*Cock*.—First, P. Allen, Kilbirnie. Second, G. Graham. Third, W. Stevens, Invermann. Fourth, R. Gardiner, Glasgow. *Hens*.—First, A. Kelly. Second, R. Houston. Third, J. Dunlop. Fourth, J. Mitchell, Perth.

PHEASANT.—First, A. Crawford. Second, M. Tode, Paisley. Third, R. Wood, Paisley.

PHEASANT (Yellow).—*Cock*.—First, J. Dunn, Galston. Second, G. Horsburgh, Glasgow. Third, T. M. Muir, Knockintiber. Fourth, J. Fisher, Dalry. *Hens*.—First, J. B. McLean, Glasgow. Second, J. Fisher. Third, J. Crawford. Fourth, C. Gardner.

PINHEAD (Buff).—*Cock*.—First, N. M. Lean. Second, R. Hunter. Third, J. Glasgow. Fourth, A. Cochran. *Hens*.—First, W. Santer, Paisley. Second, R. Hunter. Third, T. M. Muir. Fourth, W. Crawford.

GOLDEN PHEASANT.—First, J. Gray, Airdrie. Second, A. Kerr.

GOLDEN PHEASANT.—First, J. Watchmont, Stevenson. Second, J. Crawford.

HOME OR FOREIGN BIRDS.—First, J. Lambie, Paisley. Second, J. Barr, Paisley.

BEST COCK CANARY.—Silver Medal, R. Houston. *Hens*.—Silver Medal, A. Kelly.

The following were the Judges:—*Poultry*.—Messrs. W. F. Farquhar, Barrhead; J. Paton, Stewarton; D. Brown, Perth; J. Miller, Glasgow; J. Crawford, Glasgow; A. Paterson, Airdrie; J. McInnes, Paisley; and H. Todd, Paisley. *Pigeons*.—Messrs. J. Huie, Glasgow; and A. Mitchell, Paisley. *Small Birds*.—Messrs. W. Taylor, Glasgow; T. Buchanan, Glasgow; W. Orr, Perth; J. Wren, Pollokshaws; W. White, Renfrew; J. M. Lean, Paisley; A. Mitchell, Paisley; and M. Wilson, Paisley.

THE ESKDALE POULTRY SHOW.

The sixth annual Exhibition of this Society was held in the Eskdale Temperance Hotel, Langholm, on the 1st and 2nd inst. We must defer remarks till next week. Subjoined is the prize list:

DORKINGS (Any colour).—First, Miss Malcolm, Milnholm. Second, D. White, Duffield. Third, D. Hardie, Sorbie.

GAME (Any colour).—First, D. Hardie. Second and Third, J. Brough, Carlisle. Highly Commended, J. H. Wilson, St. Bees. Commended, J. Brough, Carlisle; A. Thomson, Herring Green; R. Robinson, Wighton.

DORKINGS (Silver).—First and Second, D. Hardie. *Chickens*.—First, D. Hardie. Second, T. L. Jackson, Bush.

DORKINGS (Dark).—First, T. L. Jackson. Second, R. Reid, Moat. Highly Commended, J. Corrie, Langholm. *Chickens*.—First, G. Hodley, Wetheral. Second, D. Hardie. Highly Commended, Miss Malcolm; D. Hardie. Commended, R. Reid.

SPANISH.—First, W. Paterson, Langholm. Second, J. C. Wilson, Annan. *Chickens*.—First, M. Turnbull, Melrose Mills. Second, W. Paterson. Highly Commended, W. Paterson; Messrs. Bowman & Fearon, Whitehaven. Commended, J. H. Wilson; W. Paterson.

GAME (Black or Brown Red).—First, D. Hardie. Second, J. Brough. Highly Commended, J. Brough. Commended, A. Thomson. *Chickens*.—First, W. Urquhart, Langholm. Second, J. Brough. Highly Commended, W. Taft, Hatherlie, Selkirk.

GAME (Any colour).—First, J. Brough. Second, A. Thomson.

COCHIN-CHINAS (Any colour).—First, Messrs. Bowman & Fearon. Second, R. Dalgliesh, Billholm. Highly Commended, W. Park, Abbotsmeadow, Melrose.

BRAHMA POOTRA (Any colour).—First, D. Murray. Second, A. Paterson. Highly Commended, W. R. Park, Abbotsmeadow.

HAMBERGERS (Golden-spangled).—First, A. Hatherlie, Selkirk. Second, R. Dickson, Selkirk. Highly Commended, R. Burrow, Longtown.

HAMBERGERS (Golden-pencilled).—First, W. Bowe, Carlisle. Second, W. R. Park. Highly Commended, J. Carruthers, Hopsrig; R. Burrow.

HAMBERGERS (Silver-spangled).—First, W. R. Park. Second, W. Bowe. Highly Commended, W. Bowe; Mrs. Evers, Burnfoot.

HAMBERGERS (Silver-pencilled).—First, W. R. Park. Second, J. Platt, Dean, near Bolton. Highly Commended, Miss Malcolm, Burnfoot; J. Musgrave, Longtown.

ANY OTHER VARIETY.—First, W. R. Park. Second, D. Hardie (Silver Polders).

BANTAMS (Black-breast or Brown Red).—First, D. Hardie. Second, Messrs. Bowman & Fearon. Highly Commended, J. Scott, Castlegate, Auldburgh; J. Roberts, Selkirk.

BANTAMS (Duckwing, Fife, &c.).—First, W. Myron, Jedburgh. Second, H. 14, 15, West Terrace, Darlington. Highly Commended, J. Lunn, Jedburgh.

BANTAMS (Any variety).—Prize, Messrs. S. & R. Ashton.

TURKIES.—First, T. L. Jackson. Second, D. Hardie. Highly Commended, T. J. Harrison, Singleton Park. *Poult*.—First, J. Smith, Grantham. Second, D. Hardie.

GESE (Grey or Mottled).—First, R. Reid. Second, D. Hardie.

GESE (White).—First, Miss Paterson, Terraona. Second, M. Turnbull, Commended, A. Greys, Atherrig.

DUCKS (Aylebury).—First, D. Hardie. Second, R. Latimer, Forgechrae. Commended, W. Bell, Exes Mill; D. Hardie.

DUCKS (Rouge).—First and Second, D. Hardie. Highly Commended, D. Dunn, Green Hill House, Keighley; R. Dalgliesh; A. Griev.

DUCKS (Any other variety).—First, E. Hutton, Paisley, Leeds. Second, G. R. Paterson. Highly Commended, Miss Paterson; Miss Palmer, Dashed Green; A. Robinson, Longtown.

CORAG (Any colour for first town of Langholm (Any Breed)).—First, J. L. Macdonald (Cochin). Second, W. Ballantyne (Spanish). Third, W. Bole (Hambur).

COTTAGE CLASS FOR ESKDALE (Any Breed).—First, R. Latimer. Second, M. H. Hurry, Sorbie Cottage (Dorkings). Third, Mrs. Armstrong, Kirkton (Dorkings). Highly Commended, J. Carruthers, Hopsrig; G. Oliver, Midhillfoot (Cochins); Miss Graham, Blisspath (Dorkings); C. Gentile, Auld.

SEALING CLASS.—First, G. Bell, High Street, Wighton. Second, D. Barr, Duffield. Third, W. Paterson (Spanish). Highly Commended,

Miss Palmer (Wild Ducks); T. L. Jackson (Silver Duckwings); D. Hardie (Dorkings); Miss F. Johnson, Walton House; W. Urquhart. Commended, W. R. Park (Silver Polders).

PIGEONS.

CROPPERS.—First, J. Grant, Corstorphine Hill House. Second, J. Campbell, Langholm Distillery. Commended, K. Irving, Langholm.

TOUMBERS (Almond).—First, J. Campbell. Second, R. Whittaker, Delph Hill, near Bolton.

TOUMBERS (Any other variety).—First, J. Campbell. Second, R. Whittaker. Highly Commended, Messrs. Sisson & Hume, Carlisle.

JACOBINS.—First, J. Towerson. Second, J. Campbell.

FANTAILS.—First, W. R. Park. Second, J. Thomson, Bingley.

CARRIERS.—First, J. Towerson, Egremont. Second, J. Campbell.

NEWS.—First, R. Paterson. Second, R. Davidson, Swinnie, Jedburgh. Highly Commended, R. Irving; J. Thomson.

TURBITS.—First, J. Thomson. Second, R. Paterson. Highly Commended, W. R. Park. Commended, J. Dugdale, Carlisle.

ANY OTHER VARIETY.—First, W. R. Park (Owls). Second, J. Hardie (Marpies). Highly Commended, J. Campbell.

SELLING CLASS.—First, W. R. Park (Fantails). Second, R. Paterson (Fantails). Highly Commended, W. R. Park (Turbits); J. Barton, Jedburgh (Carriers); J. Grant; J. Hardie.

CANARIES.

SCOTCH FANCY (Yellow).—*Cock*.—First, J. Kemp, Galashiels. Second, H. Donald, Galashiels. Highly Commended, J. Hope, Galashiels. *Hens*.—First, J. Smart, Galashiels. Second, J. Hope. Highly Commended, J. Cleghorn, Galashiels.

SCOTCH FANCY (Buff).—*Cock*.—First, J. Kemp. Second, R. Bell. Highly Commended, J. Hope. *Hens*.—First, J. Hope. Second, T. Scott, Galashiels.

BELGIAN FANCY (Yellow).—*Cock*.—Second, J. Kemp.

BELGIAN FANCY (Buff).—*Cock*.—First, J. Kemp. Second, T. Scott. *Hens*.—Second, J. Kemp.

FANCY FLOCKED (Yellow).—*Cock*.—First, W. Scott, Langholm. Second, J. Cleghorn, Galashiels. *Hens*.—First, R. Kyle, Hawick. Second, J. Cleghorn. Highly Commended, T. Scott.

FANCY FLOCKED (Buff).—*Cock*.—First, R. Kyle. Second, W. Finlane, Jedburgh. *Hens*.—Prize, J. Smart.

GOLDEN CHICKS (Yellow Flocked).—*Cock*.—Prize, A. Graham, Rowanburgh.

GOLDEN CHICKS (Buff Flocked).—*Cock*.—First, A. Graham. Second, T. Wilson, Hawick.

COMMON (Yellow).—*Cock*.—First, A. Graham. Second, P. Martin, Langholm.

COMMON (Buff).—*Cock*.—First, M. Raine, Langholm. Second, J. Corrie, Langholm. *Hens*.—First, T. Wilson. Second, J. Corrie. Highly Commended, J. Steel, Langholm.

COMMON FLOCKS (Yellow).—*Cock*.—Prize, W. Hutton, Milnholm. *Hens*.—First and Second, W. Hutton.

COMMON FLOCKS (Buff).—*Cock*.—First, J. Steel, Langholm. Second, R. Warwick, Langholm. *Hens*.—Prize, J. Kemp.

SWEETSTAKES (Green Cock or Hen).—First, H. Donald. Second, R. Kyle. Highly Commended, T. Brown, Hawick.

GOLDFINCHES.—*Cock*.—First and Second, A. Graham.

The Judges were Mr. Beldon, of Gaitstock, for *Poultry* and *Pigeons*; and Mr. Thomson, Hawick, for *Canaries*.

DUMFRIES AND MAXWELLTOWN ORNITHOLOGICAL SOCIETY'S SHOW.

The ninth annual competition of Poultry and Cage Birds under the auspices of this Society, was held on the 1st and 2nd inst., in the Mechanics' Institute Hall, Dumfries.

GAME (Black Reds, Blacks, and other Reds and Blues).—First, J. Harding, Dumfries. Second, J. Brough, Carlisle. Highly Commended, T. Parker, Kirkcubright. Commended, W. D. Dickson, Carroncroft.

Chickens.—First, T. Maxwell, Sloan's Cottage. Second, A. Robinson, Longtown, by Carlisle.

GAME (Duckwings, Whites, and other Greys).—First and Second, T. Maxwell. Commended, T. Hill, Collin. *Chickens*.—Medal and First, J. Brough. Second, J. Baird, Thornhill. Highly Commended, T. Maxwell. Commended, C. Turner, Dumfries.

SPANISH (Black).—Medal, First, and Second, J. Neilson, Ecclefechan.

Chickens.—First and Commended, J. Kerr, Erclefechan. Second, J. C. Wilson, Annan.

DORKINGS.—Medal and First, W. H. Arundell, Barjarg Tower. Second, W. G. F. Lyons, Kirkcubright House. Highly Commended, R. Reid, Longtown, by Carlisle. T. Parker; J. Milligan. *Chickens*.—First, T. Ferguson, Maxwelltown. Second, Mrs. Corrie, Heath Hall. Highly Commended, W. G. F. Lyons. Commended, Miss A. M. Holm.

COCHIN-CHINA (Any colour).—First, Lady J. Johnstone Douglas, Lockerbie House. Second and Highly Commended, Mrs. Moffat, Kirtlebridge. Commended, S. Cowan, Clarencefield. *Chickens*.—First, Lady J. Johnstone Douglas. Second, J. Neilson. Highly Commended, S. Cowan.

HAMBERGERS (Golden-spangled).—First, Mrs. Corrie. Second, T. Musgrave, Longtown. Highly Commended, H. Currie, Ardrossan. *Chickens*.—First and Second, Mrs. Corrie.

HAMBERGERS (Golden-pencilled).—First, R. Barrow. Second, T. Musgrave. Highly Commended, W. Bowe, Carlisle. *Chickens*.—Medal, First, and Second, R. Little. Highly Commended, W. Bowe.

HAMBERGERS (Silver-spangled).—Medal and First, J. Hunter, Goldlaw Bridge. Second, T. Musgrave. Highly Commended, J. Douglas, Cairnside. *Chickens*.—First and Commended, J. Douglas. Second, W. Bowe. Highly Commended, R. Kerr, Barjarg Tower, by Auldgarth; J. Hunter. Commended, J. Douglas.

HAMBERGERS (Silver-pencilled).—First, J. Musgrave. Second, H. V. Johnstone, Broadholm. *Chickens*.—First, J. Musgrave. Second, W. Little, Dumfries.

BRAHMA POOTRAS.—First, G. Inglis, Cairn. Second, Miss M. Gardiner, Murrayton. *Chickens*.—First, T. Johnstone, Terregles. Second, T. S. Gladstone, Capenoch.

ANY OTHER VARIETY.—First, T. W. Campbell, Walton Park House.

Second, Miss M. Gardiner (Silver Polands). Commended, T. W. Campbell; G. Inglis, Corgen, Troqueer (Houdans).

DUCKS (Aylesbury).—First, Miss Johnstone Douglas. Second, W. G. F. Lyons. Commended, T. Johnstone, Waterside.

DUCKS (Bonen).—Medal and First, T. Parker. Second, Miss Johnstone Douglas. Highly Commended, T. Parker. Commended, Miss M. Gardiner.

TURKEYS (Black Norfolk).—First, G. Inglis, Gargen. Second, Miss A. McGill, Rotchell.

BANTAMS (Gold or Silver-laced).—First, T. Douglas, Thornhill. Second, W. W. Anderson, Moffat. Commended, J. P. Richardson, Dumfries.

BANTAMS (Black).—Medal and First, R. Murray, Maxwelltown. Second, Master W. Milligan, Millbank. Highly Commended, Mrs. Conpland, Dumfries.

BANTAMS (White).—First, T. Hutchison, Mouswald. Second, J. Maxwell, Allanton Mill. Highly Commended, R. Teenan, Lochside.

GAME (Black Reds).—First, J. Sharp, Johnstone. Second, C. Harper, Maxwelltown. Highly Commended and Commended, T. Maxwell.

GAME (Duckwings and Greys).—First, T. Maxwell. Second, Miss S. F. Munn, Rockhall. Highly Commended, T. Jardine, Lockerbie.

ANY OTHER VARIETY.—Prize, S. Darcey, Maxwelltown.

PIGEONS.

TUMBLERS (Common).—First, J. Sharp. Second, J. Love, Dumfries. Highly Commended, J. Marchbank, Dumfries. Commended, R. Kerr.

CARRIERS.—First, J. Thomson, Maxwelltown. Second, J. Sharp. Commended, J. Thorpe, Dumfries; T. Maxwell.

POUTERS.—First and Second, J. Sharp.

JACOBIANS.—First and Second, J. Sharp.

FANTAILS.—Medal and First, J. Sharp. Second, Miss Knott, Essex Park. Commended, T. Douglas.

ANY OTHER DISTINCT BREED.—First, J. Thomson (Barbs). Second, J. Conpland (Barbs). Commended, J. Sharp (Spots); T. Maxwell (Magpies).

BRITISH BIRDS.—Prize, J. Maxwell, Friars' Vennel, Dumfries (Crossbill). FOREIGN BIRDS.—Prize card, A. Imrie, Auldgrith Inn.

CANARIES.

SCOTCH FANCY (Yellow).—Cocks.—First and Third, J. Thorpe. Second, J. Graham, Kilmarnock. Hens.—First, J. Graham. Second, R. Davidson. Dumfries. Third, J. Thorpe.

SCOTCH FANCY (Buff).—Cocks.—First, J. Thorpe. Second, J. Graham. Third, R. Purdie, Dumfries. Hens.—Medal and First, J. Thorpe. Second, J. Little. Third, A. Hope, Maxwelltown.

PIEBALD (Yellow).—Cocks.—Medal and First, J. Thorpe. Second, J. Little. Third, D. Gibson, Lochmaben. Hens.—First, Master C. Grieve, Dumfries. Second, John Thorpe, Dumfries. Third, J. Little.

PIEBALD (Buff).—Cocks.—First, J. Thorpe. Second, R. Edgar, Maxwelltown. Third, R. M'Innes, Dumfries. Hens.—First, J. Thorpe. Second, J. Little. Third, R. M'Innes.

BELGIAN (Yellow or Buff).—Cock.—Prize, J. Thorpe. GREEN.—Cock.—Prize, W. Pool, Dumfries. Hen.—Prize, R. Edgar.

GOLDFINCH MULES (Yellow).—First, R. Bryden, Lochmaben. Second, J. Kirk, Dumfries. Third, W. Welsh, Dumfries.

GOLDFINCH MULES (Buff).—First, R. Edgar. Second, W. Fleming. Third, Master D. Brown, Dumfries.

GOLDFINCHES.—First, John Thorpe. Second, J. Wilson, Dumfries. Third, A. Martin, Castle Douglas Station.

JUDGES.—Poultry and Pigeons: James Stevens, Esq.; M.D. Ardrossan; Mr. James Paton, Stewarton. Canaries: Mr. George Grant, Paisley; Mr. George Crawford, Beith.

THE SHEFFIELD ORIGINAL FANCY RABBIT SOCIETY'S SHOW.

THIS Show was held at the Inkerman Tavern, Alma Street, on December 26th, 27th, and 28th. Nine silver cups were awarded in the Young class. It was the largest and best Show ever held in Sheffield. There were fifty pens of Rabbits exhibited, but the chief attractions of the Show were three Rabbits, measuring in the order named—W. Allison's Buck, 23½ inches; Mr. Lindley's Buck, 22½ inches; and Mr. Mangham's Doe, 22 inches. The following took prizes in the young Rabbit class:—

LENGTH OF EARS.—First (Silver Cup).—Lindley, Buck. Length of ears, 22½ inches; width, 5½ inches. Second (Silver Cup), W. Allison, Doe. Length of ears, 22½ inches; width, 5½ inches. Third (Silver Cup), W. Allison, Buck. Length of ears, 21½ inches; width, 5½ inches.

BLACK AND WHITE.—First (Silver Cup).—Mangham, Doe. Length of ears, 21 inches; width, 5 inches. Second.—Webster, Doe. Length of ears, 19½ inches; width, 4½ inches.

GREY AND WHITE.—First (Silver Cup).—Frith, Doe. Length of ears, 19 inches; width, 5½ inches.

YELLOW AND WHITE.—First (Silver Cup).—Lindley, Doe. Length of ears, 21½ inches; width, 5½ inches. Second.—Hay, Buck. Length of ears, 19½ inches; width, 5½ inches.

TORTOISESHELL.—First (Silver Cup), W. Allison, Doe. Length of ears, 19½ inches; width, 5 inches. Second.—Elliott, Buck. Length of ears, 19 inches; width, 4½ inches.

SELF-COLOUR.—First (Silver Cup).—Beaumont, Doe. Length of ears, 20½ inches; width, 5½ inches. Second, W. Allison, Buck. Length of ears, 22 inches; width, 5½ inches.

WEIGHT.—First (Silver Cup).—Frith, Doe. Weight, 9 lbs. Second, J. Leigh, Doe. Weight, 8 lbs.

W. ALLISON, Sec., 8, Cheney Row, Sheffield.

PHILOPETERISTON SOCIETY.—The grand annual Show of Pigeons of this old Society will be held at the Freemasons' Hall, Great Queen Street, on Tuesday, January 14th, from 1 to 4 P.M. Admission by ticket only, to be had on application to

the Hon. Sec., Matthew Hedley, Esq., Claremont, Red Hill, or on the day at the above Hall.

DOINGS IN A SMALL APIARY IN 1867.

ALTHOUGH the bee season of 1867 has been a decided failure, I venture to give an account of some little doings in my apiary, believing they may possess an interest to some readers of our Journal.

The spring found me in possession of three hives of black bees, each in good condition. I had restricted myself to this number, having in view the introduction of the Ligurian species, on which some notes may not be uninteresting at a future period. I have had no swarms, and no honey to appropriate.

Of my three hives, A, a two-year stock in a 14½-inch square straw hive with a wood top, was very strong. Two bell-glasses and a 9-inch square glass-framed super were placed on in May, but not until late in June were they fully taken to. In July the bees ceased comb-building, also the storing of honey. None of the combs was ever sealed; the honey being of a very dark colour, I allowed the bees to consume it, or remove it to their stock hive. Besides this, in October I had to give the stock 11 lbs. of syrup food, to make it up for wintering. The empty combs are the only produce.

B, a two-year stock, in a common round hive, was used as a non-swarm in 1866, as also this year, by placing a nadir hive under it late in May. By the middle of July there were only three combs partially built, and little honey stored. Seeing that I should obtain no yield of honey, I at once removed the nadir, drove the bees into an empty skep, and transferred them into a home-made, square, straw, bar-and-frame hive. From their original hive I took 13 lbs. of very dark-coloured honey. This, together with sugar syrup, was given them in their new domicile, and they are now in fair order for wintering.

C, the unfortunate stock of 1866, wintered well. It was fed a little in spring and was the most active of the three. A 13-inch glass-framed super was put on in May; at the end of July this was three-fourths full of combs very partially sealed; the honey was of a very dark colour. Being unfit for table, I have distributed it to make up my stocks for winter. In October this stock required 6 lbs. to make it up to 20 lbs. nett.

This autumn I have sought to extend the system of driving, and have gained some converts, as well as effected a saving of bee life. In all I have driven seventeen stocks successfully, and have only to record being stung twice. Here, amid other remedies for the sting of a bee, I would recommend the application, immediately after extracting the sting, of a little—very little—pure spirit of ammonia.

Of the seventeen driven stocks, some were added to other stocks with varying success. A few, kept single, I have distributed to be again fed up, and, so far as I now know, believe they will succeed. The bees, in each case, I was allowed to have for the driving.—J. G. C., South Northamptonshire.

(To be continued.)

OUR LETTER BOX.

NORTHERN POULTRY CLUB'S SHOW.—We shall give next week a report of this, together with a list of the awards, both having arrived too late for insertion to-day.

COLOURED DORKINGS (H. S.).—If we had to choose, we should breed from cocks and pullets with their second eggs. It does not at all injure Grey Dorkings to be crossed with the Silver-Grey; but the slightest mixture of grey is fatal to the Silver-Grey, because any mixture of white, however trifling, in the tail or on the breast, is a disqualification. It is easier to breed the pullets than the cocks, therefore the most scrupulous care must be taken in selecting the cock for breeding.

SOFT FOOD FOR FOWLS (C.).—We do not for a moment believe feeding on soft food has a tendency to make combs grow; but we are quite sure feeding on potatoes has much to do with making them fall over, in consequence of the lack of condition which such food induces.

WEIGHING A FOWL WITH HEAD DOWNWARDS (Ambleside).—The cock was suffering when you weighed him; but there is no doubt the cause of death was the rupture of a vessel from the downward flow of blood. You should always weigh a fowl in a bag or basket.

SPACE FOR POULTRY (J. E. M.).—Under the trees will do very well. If you will enclose seven postage stamps with your address, and order the "Poultry Book for the Many," you will have it free by post, and it contains plans, &c., for poultry enclosures.

BUYING POULTRY (A Lover, &c.).—Write to some advertisers in our Journal, and buy a cockerel of one vendor, and the pullets of another. Buy the "Poultry Book for the Many" and the "Garden Manual," both to be had at our office. A poultry show in and near London has been repeatedly tried, and as often failed.

WEEKLY CALENDAR.

From observations taken near London during the last forty-one years, the average day temperature of the week is 41.7; and its night temperature 31.4°. The greatest heat was 68° on the 19th, 1828; and the lowest cold 41° below zero, on the 19th, 1838. The greatest fall of rain was 0.88 inch.

THE GLADIOLUS: ITS CULTURE AND DISEASES.

SOME of your correspondents seek for information on the Gladiolus and its culture, I venture to give my experience on the subject, having grown this gorgeous autumn flower extensively for the last few years.

The following is my mode of culture, both for flowering the bulbs, and for raising and growing seedlings.

First let me premise that I have never suffered much from the fatal disease, like

"D.,"*Deaf*, and others. In the wet and cold September of 1866 I had a collection growing on a border with rather a stiff soil, and on lifting the bulbs in October some of them were marked with black spots. A few of the best named sorts which were affected I tried to save in the following manner:—At lifting time I dried them thoroughly off, and then potted them, with a handful of wood-charcoal dust round the bulbs. The soil in the pots was kept dry till April, when the pots were plunged in a frame, and the bulbs started with a slight bottom heat. In June the plants were planted-out, and flowered well, and the new-formed bulbs were perfectly healthy when taken up in October. Last year at lifting time I picked out a few spotted bulbs, which have been kept separate from the others, and will be planted in April or May with some charcoal dust round them.

I think all black-spotted bulbs should be planted later in the season than the healthy ones. If planted in February or March they will lie some time in the ground before growing, and the rot is then sure to end fatally. The cause of these black spots on the bulbs, if due to atmospheric influences, may be as mysterious as the Potato disease, and as difficult to prevent.

As to the time of planting, I believe healthy bulbs may be put in from February to May, or June, according to the weather and state of the soil. The *Cardinalis* and *Ramosus* sections, being the earliest in flowering, should be planted first; and, ending with the *Gandavensis* varieties in April and May, a succession of flowers may be kept up from July till October.

Great stress is laid by some growers of the Gladiolus on the advantages of changing the ground it grows on every year. Of course, if no fresh soil is added, a change to another place would be desirable; but I find this is not necessary where plants from pots are planted-out, for they are always in fresh compost, and the Gladiolus roots do not go very deep, nor ramify much. When the Gladiolus is grown in rich stimulating soils, no doubt it will produce the largest and finest spikes; but I believe it will do this at the expense of health in the bulbs. I find the varieties grown in the borders and *Rhododendron* clumps, in poor sandy peaty soil, have the healthiest bulbs when lifted, and produce the most "spawn." The border in which I grow my seedlings has now been planted with them three years consecutively, and I can perceive no deterioration in their growth or disease amongst them. Every autumn, when the little bulbs are taken up, some light turfy soil,

mixed with very rotten deer dung, is dug into it, and at planting time, in April, a good dressing of sharp red sand is added. After flowering, and as soon as the leaves begin to change colour in October, the bulbs are taken up, and spread in a dry airy room, secure from frost. After they are thoroughly dried, the old stems are cut or clipped off, and the old dead corms removed, saving all the increase of the different varieties.

As there is a great difference in the shape of the flower in the Gladiolus and the way it is placed on the spike, owing to the *Ramosus* or *Floribundus* blood inherited by the different varieties of *Gandavensis*, I think the time is coming when only the best-shaped flowers and spikes will be tolerated at exhibitions of this flower. About twenty years ago, when Pansies were not of so good a shape as they are now, I had a tolerably good collection of the best sorts grown then. On the occasion of a visit from a neighbouring gardener he inspected my bed, and begged a few cuttings, saying his at home were all very "sow-lugged." Now we are in the transition state with the Gladiolus, and all "sow-eared" and winged flowers will have to be discarded in collections of show flowers.

In 1865 I flowered a seedling, raised from *Monsieur Blomet*, with all the petals nicely rounded, and of nearly the same size; in fact, quite a florists' flower. This seedling I crossed with *Queen Victoria*, and some others of the best-shaped flowers I had out at the time, and saved some seed from the crosses. This autumn the young bulbs will bloom, and I expect something good from them in shape and colour.

The autumn of 1865 was the best I have known for saving Gladiolus seed; for, with the precaution of setting the flowers, nearly every kind seeded freely in August and September. I shall have this autumn between five and six thousand bulbs to bloom, raised from seed sown in April, 1866, and it is astonishing how small a bulb will bloom late in the season.

I find it is the safest way in our uncertain climate to grow in pots some of the most expensive and finest kinds when seed is wanted from them; you can then keep them under cover and from the bees. It is quite a sight to watch a collection of Gladiolus in flower on a sunny morning, for every few minutes large lumbering humble bees will be sucking in the nectaries, and as fast as one is satisfied another will be ready to take its place.

In 1866 and 1867 I saved but little seed from my collection in the open air, and depended on bulbs grown in pots.

I find the best way of raising seedlings is to sow the seed in April on a south border, the soil being made very light with plenty of red sand and leaf mould. If the seed is sown in pans or boxes, the roots become cramped, and the small bulbs never grow so fast as in the open air.

As "B." enumerates some of the varieties he has found the best for shape and colour, I have done the same, and shall begin with the new sorts sent out in 1867. *Adolphe Brougnart*, flamed orange and red; *Elicien David*, cherry rose, striped carmine; *Lady Franklin*, white ground, flaked with carmine and rose—in my opinion the best shaped flower

sent out in 1867: Princess Mary of Cambridge, white, blotched with carmine; Sir W. Hooker, cerise, blotched with carmine.

Of the older flowers, without taking any notice of the year in which they were sent out, I consider the following as the best:

White or Light Varieties.—(Queen Victoria, Enrydice, Eleanor Norman, Shakespeare, and Milton, creamy white and flaked.

Red and Scarlet.—Meyerbeer, Maréchal Vaillant, Fulton, Ensign, The Colonel, Comte de Morny, and Napoleon III.

Cerise.—Bernard Palissy, Le Poussin, John Waterer, and Dne de Malakoff.

Lilac.—Anaïs, Belle Gabrielle, Empress Eugénie, and Madame Furtado.

Yellow.—El Dorado.

Rose.—Némie, Princess Clothilde, Penelope, Charles Diekens, and Madame Vilmorin.

The few I have grown of Mr. Standish's varieties, such as Eleanor Norman, The Colonel, and Ensign, I consider better shaped than the very best of the foreigners.—WILLIAM TILLERY.

THE ROYAL HORTICULTURAL SOCIETY'S SPRING AND SUMMER SCHEDULES FOR 1868.

THESE are now before the public, and, taken as a whole, are arranged in a very liberal spirit and on an extensive scale. In looking through them, however, there are a few things that strike one as being open to improvement.

First, greater inducements are offered to the trade than there are to amateurs and gentlemen's gardeners. Both of the latter have to compete at a great disadvantage with the trade for this reason—neither the amateur nor the gardener has the stock to select from that the nurseryman has, nor have they conveniences to produce plants or flowers, at an early period of the season especially, such as the nurseryman has. In either case, the amateur or gardener must have his houses filled to overflowing with subjects suitable for his family or his employer's purposes. There are very few places in the country where the gardener will find houses for the express purpose of growing plants, &c., for exhibition only—a thousand things are generally required from the gardener, whether he has few or many glass structures for horticultural purposes.

In glancing over the schedule of the show of Hyacinths and Early Spring Flowers, to be held on the 14th of March, the highest prize is offered to nurserymen only, and Class 2 being open, the highest in it is almost sure to go to the trade. The great point in their favour is that as soon as their stock of bulbs arrive in the autumn, they can at once select the very strongest and most suitable for their purpose, whilst the amateur or gardener must do the best he can with what he has sent him. The wording of the schedule, in my opinion, should therefore be reversed, allowing the gardener or amateur to compete on more equal terms with the nurseryman. This could be done by making a division for amateurs in Classes 1 and 2, which should read thus: "Class 1: 18 Hyacinths distinct, nurserymen, £2, £1, 15s. Class 1, amateurs: 18 Hyacinths, distinct, £3, £2, £1;" and Class 2, instead of being open, should be arranged in a similar way. This would give the amateur a fair chance, and the consequence would be that the number of exhibitors would be very much increased, thereby making the Society's exhibition much more attractive to the public, and consequently bringing together a much larger number of visitors.

A similar drawback again occurs in the schedule for the Show of Roses and Early Spring Flowers, to be held on the 18th of April. Nine classes out of thirteen are open, thus giving the trade nine chances to the amateur's four. Something similar occurs in most of the succeeding schedules.

At the Grand Summer Flower Show, to be held on the 2nd of June and three following days, in Class 1 there should be provision made for the amateur as well as the nurseryman, by giving another set of prizes of equal amount, thus confining the competition to nurserymen in one half of the class, and to amateurs in another. There are few amateurs who could compete, with any hope of success, with the fine collections of Messrs. Veitch, Turner, Fraser, Glendinning, and others. The consequence is that many fine collections are kept at home, and the exhibition loses much in effect and extent, visitors telling their friends who may have made up their minds to see the exhibition on the following day that it is scarcely worth their going to see, as the competition is confined to five or six exhibitors, and that on this occasion there are only the same plants they have frequently seen before exhibited again. Offer the amateur and gardener the same

advantages, and we shall see five times the number of plants exhibited, and a much greater amount and variety of talent and skill displayed by exhibitors. Fresh ideas will be introduced at each exhibition, and instead of seeing large one-sided masses of colour, we shall see plants that will be a credit both to the managers of our exhibitions and to cultivators as well.

The schedule for the great Rose Show, to be held on the 30th of June, is much more equally balanced, and shows at a glance that much more care and thought have been used in compiling it. At this show the amateur competes on equal terms with the nurseryman; and if this can be arranged for the lovers of the Rose, why is it not done for the lovers of plants generally? There are fully as many gardeners and amateurs who are quite as enthusiastic in the cultivation of other flowers. I need not here prolong my criticism, as, no doubt, this letter will be the means of drawing out the opinions of others who are more interested in the matter than I am.

I would remind the Council of the Royal Horticultural Society that greater punctuality is necessary in the distribution of their medals, &c., after they have been awarded to exhibitors. If these have to wait six, nine, twelve months, or two years before they receive their medals, much of the interest they would otherwise feel is lost, and the employer is apt to say, "It is of no use your exhibiting at the Royal Horticultural Society, for you will have to wait a year or two before you receive your prize."—F.R.H.S.

CONIFERE AT MR. MITCHELL'S, PILTDOWN.

IN the latter part of the summer of 1866 I paid a visit to Mr. Mitchell's nurseries at Piltown, in Sussex, a notice of which appeared in the Journal of September 18th of that year. The duration of the visit being limited to a few hours, the notes were necessarily restricted to a general review of the nursery stock, among which some fine specimens of Conifers were especially mentioned; but there are also many others of the same and different species that were then passed over. Among them are some of the largest and most perfect forms of particular kinds of these beautiful and stately trees that can be seen.

Nor was it by the particular specimens only that my attention was strongly interested, for the stock of the different kinds, in some instances to be counted by hundreds, was similarly remarkable for healthy growth, colour of foliage, and every essential requisite for forming fine specimens. I was, therefore, very desirous of ascertaining as far as possible under what conditions these invaluable subjects for the adornment of our gardens and grounds could thrive so uniformly well. If the Editors and readers will accept this as a sufficient reason for again bringing these nurseries before their notice, they will also judge how gladly I accepted an invitation from Mr. Mitchell to again visit Piltown, and make such further inspection and observations as my time permitted.

Doubtless, the soil and situation of Piltown are the paramount influences in producing the free and perfect growth of every kind of Conifer in cultivation there; but to these must also be added the vigilant care with which they are watched over by the proprietor, aided in no small degree by the intelligence and superintendence of his son. Conifers of some kind will grow almost everywhere. In situations less favoured than Piltown, if they do not thrive quite so satisfactorily, much may be done by cultivation.

It is a mistake to suppose that having selected and planted out one or more of the many beautiful kinds now so easily to be obtained, there is an end to all further care about it, except to those easy-going people who are indifferent whether their plants become specimens worth regarding hereafter or not. Our (the gardening) world is not so quietly ordered that we can treat any class of subjects as an exhibition of waxwork, the only difference being that the vegetable figures are expected to grow larger. Such at least is not my limited experience as regards Conifers, especially when the plants are young, although admitting the great fact that the many thousands planted out annually for ornamental purposes only, receive little or no attention after planting, and that very many of them do well. It does not follow, however, that many might not do better, even if it is prudent sometimes to "let well alone." They, therefore, in common with every class of plants taken under man's care, require a certain amount of cultivation according to their habit and age; it is a requisite to all improvement, and even to the maintenance of the natural condition of kinds brought from distant lands.

To note in this place the different points of attention that might be judiciously applied to the various species of Conifers, especially while the plants are young, would be to digress too far from the subject of this paper. I may, however, add that having taken upwards of eighty kinds under my care, I have found that the growth of young plants can be promoted, and their symmetry improved, by carefully studying their requirements. This study mainly consists in knowing the kind of soil in which they are found in their native home, the altitude above sea level at which they thrive best, the mean annual temperature, and the extremes of winter and summer. To judge from these data (some of which may be easily ascertained for practical purposes from any of the excellent physical atlases that have of late years been published) the probability of the species succeeding or the reverse, will save much after-trouble and disappointment. This is particularly applicable to the Cypress and its allies (Cupressineæ), as *Thuja*, *Biota*, *Retinospora*, and *Juniperus*. Among these and some of the *Pinus* tribe the liability to suffer from extreme cold, high winds, and unsuitable soil, renders more care necessary than for most of the *Abies*, *Pinuses*, &c., found in latitudes corresponding to our own, and which scarcely require any attention.

At Piltown many of the most important ornamental Conifera find the elements necessary to their well-being. The soil is a deep, rich, friable loam, naturally well drained by the gentle slope of the nursery on one side towards the S.E., and in another direction towards the S. It retains sufficient moisture in hot and dry weather to promote free growth, without causing the temperature to sink too low in the cold weather that proves so fatal in this country to the Conifera of warmer climes. Instances will be noticed presently. The pure bracing air of the downs, tempered by the vicinity of the sea, less than twenty miles distant, is also an additional circumstance eminently favourable. With these preliminary remarks I now offer some notes of the principal kinds growing there.

Araucaria imbricata claims the first notice on account of the size many of the specimens have attained, their number, and their perfect growth. The largest, near the entrance gate to the nursery on the east of the road opposite Mr. Mitchell's residence, is probably the finest specimen in England. Its height is upwards of 40 feet; the circumference of the trunk near the ground is 6½ feet; its lowest branches springing from the trunk are 11 and 12 feet in length, thence gradually and uniformly diminishing in length towards the top. The ramifications of each branch are similarly uniform and equidistant, most numerous at the extremities of the main branches, and by their weight give these a graceful curvature and somewhat pendulous habit (the true character of the *Araucarias*), the curvature and pendulous character becoming less and less towards the top in proportion to the length of the branches. The tree bore cones last year, but none this season. From its height and colour of foliage, this magnificent tree is a conspicuous object from nearly every part of the nursery. It was planted about twenty-six years ago, and it is manifest that its progress has been uninterrupted under every circumstance of a variable climate.

The next tree, on the other side of the gateway, is about 30 feet in height, resembling the first in all respects. In a line with these two grand plants is a continuous row of upwards of sixty others, varying in height from 20 to 30 feet. In front of them, a well-kept roadway runs the whole length of the line; on the other side of this roadway, and opposite the first row of *Araucarias*, is another line of upwards of forty more of like magnitude, thus forming an avenue of unexampled interest. A single specimen of *Araucaria* is eminently picturesque, always causing admiration when the specimen is well grown. When, therefore, so large a number of this remarkable South American Conifer is found at one place an extraordinary feature is presented to view, so striking, so unusual in this country, that the scene dwells in the memory as a strange sight seen in a foreign land, or read of in books relating distant travel. This impression is very forcible at a point where, owing to the nature of the ground, the pathway and avenue are diverted from the straight line; the space behind the *Araucarias* on either side being planted with various other Conifers and exotic shrubs, all traces of native vegetation are shut out of view, and the illusion of being suddenly transported to some unknown region, if indulged in for the moment, is complete. It is gratifying to record the fact that the intense cold of last winter, so disastrous to many *Araucarias*, did not inflict the slightest injury on these noble plants. Mr. Mitchell has many other young plants in excellent condition.

Biota (Thuja) aurea.—This Conifer has become such a ge-

neral favourite, that plants of it are now met with almost everywhere, and in every nursery the stock of it is generally found to be conspicuously planted, or in such numbers as to attract attention. Piltown is no exception to this rule, great numbers in different parts of the nursery attest the universal demand for this pretty ornamental shrub. The attention of visitors is at once arrested by the two fine specimens near the great *Araucaria*. These plants are now about 5 feet, or a little more in height, with a circumference of 18 feet; their growth is perfect throughout, and in form spheroidal almost approaching globular, the diameter being but a trifle greater than the height. *Biota aurea* is one of the handsomest lawn plants ever introduced, being equally suitable for small as for large plots, in the latter case more than one specimen might be planted. It may be frequently noticed that as *Biota aurea* increases in size and age, the bottom becomes thin, thereby exposing the stems of the shrub. When this is the case, it will be found in many instances that the roots have penetrated deeply into a barren subsoil, whence they can derive no nourishment. I have found this defect to be partially checked by renewing the soil around the plant. In nurseries this defect is almost entirely avoided by the occasional transplanting of the stock.

Thuja gigantea.—There is a question of nomenclature affecting this species which it is very desirable should be set at rest. It has also been called *Libocedrus decurrens*. According to Mr. Berkeley, the lamented Lobb, who discovered this and the *Thuja* hitherto known as *T. Lobbi*, did not name these kinds as we have them, but owing to some oversight the names became as it were transposed, the specific "*gigantea*" being applied to the kind *Lobbi*, and *decurrens*. Judging from the habits of the two species, the rapid growth of *T. Lobbi* sometimes increasing its height as much as 3 or 4 feet in one season, would the more readily suggest "*gigantea*," than the slower and more compact growth of the other. Every honour should be paid to the memory of Lobb, who may be regarded as one of the martyrs in the cause of botanical and horticultural science. His name can with propriety be retained for one of the kinds. Why *Libocedrus* should have been applied does not yet appear sufficiently clear, unless there are points of difference in common with the other species still known as *Libocedrus*, to warrant their separation from the *Thuja*, as a distinct genus. The specific "*decurrens*" is objectionable, as not expressing any property in the kind, nor of botanical usage that I am aware of. Synonyms should, if possible, be avoided; and it would be an immense gain to botany if some competent authority could be established, not only to revise, but to simplify existing nomenclature—a task well worthy of being undertaken.

The large specimen at Piltown of *Thuja gigantea*, or if we are to call it aright, *T. Lobbi*, is now about 13 feet high; the circumference of the branches at half that height is much greater than at the bottom. I am inclined to believe that this is not the general character of the tree, having never observed it nor any tendency to it in other specimens. This is, however, the largest I have ever seen. The deep glossy green of its foliage renders it a most beautiful and picturesque object at all seasons; its hardness has also been fully established. It appears to be shy of removal, probably on account of scarcity of rootlets. I have to regret the loss of a good plant 6 feet high from this cause. It might be overcome by grafting on a more vigorous kind, but this process is very objectionable in many Conifers.

Thuja sibirica, or *plicata*, for I believe them to be identical, is too well known to need description. It is more valuable for contrast with other Conifers in colour of foliage and formality of growth than as single specimens. Mr. Mitchell's largest is about 12 feet high, quite conical in shape—the characteristic of the species. I know of no Conifer so frequently planted where it ought not to be as *T. plicata*, the colour of its foliage only showing to advantage when contrasted with other species. A dwarf variety of it, called *T. minima*, is deserving of a place under similar restrictions.

Cupressus Lawsoniana.—The hardiest and most graceful of all the Cypresses proper, and therefore the most valuable of them for ornamental purposes. From its readiness to produce seed, even in a young state, it might become as common as Larch if it possessed any economic value, but with the exception of some of the *Junipers* none of the Cupressine yields timber applicable to any general purposes, being far surpassed in this respect by many of the *Pinuses* and *Abies*. Like other species of this family, it appears to be susceptible of change under cultivation and on different soils, showing various forms

of variegation and colour of foliage. Specimens at Piltown are numerous, and seedlings from them occupy a whole quarter.

Juniperus ericoides is one of the specialties of Mr. Mitchell's nursery. It is really a very pretty tree, and deservedly increasing in favour. Less formal and rigid than the Irish or Swedish Juniper, the Heath-like form of its foliage during the period of growth gives it a very distinctive character. I have seen this plant inserted in more than one nursery catalogue under three different names. This ought not to be.

Juniperus virginiana variegata.—Excepting the Holly and Euonymus, the best, most distinct, and most beautiful forms of variegation in hardy ligneous plants undoubtedly occur in many deciduous ones. The variegation in Coniferae seems to impart an unhealthy appearance to the plant that cannot command even the ordinary epithet of "pretty," especially at the time when the variegation is most wanted—that is, in winter. Such, at least, is my impression of it. Nevertheless, it would be unfair to pass unnoticed the variegated form of the old Red Cedar, which at Piltown and in other nurseries shows a marked contrast with other kinds, and is one of the most distinct in cultivation.

Cedrus deodara.—If we were to assign social positions to the different kinds of Coniferae, the Deodar would claim the rank of royalty, as one of the grandest and most majestic trees known. Yet its high rank would not have brought it under special notice in this place were there not some evidence respecting it desirable to be obtained. Its perfect hardiness is now doubtful, for large plants of it 10 and 12 feet high in Messrs. Ivery's nursery at Dorking were killed to the ground last winter, and had to be dug up; but there the temperature fell to several degrees below zero. At other places we hear of its having been much injured. My tree, about 18 feet high, had scarcely a leaf browned, but it had not to endure much more than 20° of frost. What is its limit of endurance?

Another question connected with it is of some botanical interest. Is it a distinct species, or only a variety of *C. Libani*? As it increases in age it appears to approach more and more closely to *Libani*, especially as regards foliage—a circumstance first pointed out to me at Linton by my respected friend Mr. Robson, and, I think, noticed by him in these pages. At Piltown the soil, &c., doubtless influence its growth, but the largest plants, 15 to 20 feet high, are forming large spreading branches precisely after the habit of *C. Libani*. Difference of locality where found produces differences in kinds, which may disappear when both or all are brought together, as it were, on neutral ground, remote from the original districts. There is a problem to be solved which may not unlikely diminish very sensibly the long lists of species, alike burdensome to the memory of the followers of science as it is perplexing to the uninitiated.

Cephalotaxus Fortunei.—Here, again, is a question of nomenclature, there being two kinds under this name—one called the male, the other the female—but upon what grounds? Mr. Mitchell's largest plants of both kinds are well-grown specimens, showing their habit and character very clearly. The species hitherto known as the male has this year produced a quantity of fruit, the berries being in size and form somewhat like those of the common Aucub, and, when I saw them, green and hard; the flowers were not observed at the proper time, otherwise the sex of the plant would have been determined. *Cephalotaxus* is a useful addition to our Yews, forming a compact and circular bush of moderate growth, with foliage bolder, and in one kind lighter in colour, than any other of the family. It will be seen to best advantage in large collections, planted singly or in pairs apart from other trees. Like all the Taxads, it will evidently bear pruning to any extent.—ADOLPHUS H. LEST.

in-doors by a wet or dry atmosphere on the production of pollen; but I am decidedly convinced, from careful watching, that in a dry hot atmosphere out of doors I could seldom obtain pollen to operate with, whilst on a cool day, with a rather moist atmosphere, I have found pollen always abundant. Therefore, as pollen is the agent needed for fructification, I consider that what holds good out-doors in producing the desired effects should be the aim of the cultivator in an artificial temperature.

—WILLIAM MELVILLE, *Dalmeny Park*.

THE CULTURE OF TREE MIGNONETTE.

It is very easy of culture, and by exercising a little judgment in the sowing of a few seeds at different seasons of the year, and care in cutting away the dead flowers as they appear, it may be had in bloom in the conservatory every month in the year. It may be formed into various shapes according to the taste of the cultivator. Some prefer growing it in the shape of a cone, with one plant in the centre of a pot, the stem of the plant tied to a neat stake, the side shoots regularly stepped and trained, and the flowers pinched-off as they appear, till the plant has attained its desired height and size. Others choose to have five or six plants in a 32 or 24-sized pot, and when these are neatly trained they are very useful, and never fail to be admired at this season and onwards for several months.

I have grown a few very pretty standard Mignonette plants, and as they are generally much admired, I will briefly detail their cultivation.

About the end of March seed was sown in several small 48-sized pots, placing three or four seeds in each. The compost used chiefly consisted of decayed turf pulled to pieces with the hand, but not riddled, intermixed with horse droppings passed through a fine sieve; sand being added to keep the compost open. In a mixture of this description, Mignonette seems to thrive well and bloom freely. When the seeds were sown the pots were placed in a cold pit, and as soon as the seedlings were large enough to distinguish which were the largest and strongest plants, the best were selected to remain, and the others thinned-out, and thrown away. As soon as the pots were filled with roots, but before the plants became pot-bound, these were moved into 6-inch pots, and in this size single plants will form good heads of bloom if occasionally assisted with weak manure waterings.

Some prefer larger-sized pots in order to grow extra-strong plants, but I rather like 6-inch pots, for they can then be placed in a small vase, and used occasionally for dinner-table decoration.

When the plants were several inches high, a neat stake was placed to each to keep them erect. The side shoots as they appeared were carefully pinched-off near to the main stem, carefully leaving one or two leaves at the base of each successive shoot to strengthen the plant, and keep the roots active. This I consider rather important, as, if the plant were denuded of all its leaves as the stem progressed, its health would become impaired, and premature decay would set in. Much the same course was pursued until the plants had attained the desired height.

As the plants became established they were removed from the cold pit, and placed on a bed of coal ashes out of doors. They were stopped at heights varying from 16 inches to 2 feet, and as the flower buds appeared these were regularly pinched-out, to force the plants to form a neat bushy head, until about the end of September, when each was furnished with a profusion of shoots, which were allowed to expand their bloom. By pinching-off the decayed blooms, the plants will continue to flower throughout the winter months; but to secure the perfection of fragrance, they require both sun and air, and, consequently, when convenient, should be placed in proximity to the openings by which the air is admitted into the houses, —QUINTIN READ.

HAVE MERCY ON YOUR PEAR TREES.

I much regret to see, in your number of the 2nd inst., that my old instructor in Rose-budding, Mr. Charles Ellis, of Upper East Sheen, has been guilty of the great imprudence of allowing 276 fruit to ripen on a young Beurré Clairgeau Pear tree, only 11 feet high; and, not content with this, actually publishes the fact, with the view of encouraging others to go and do similarly.

After profiting by Mr. Ellis's instructions in Rose-budding,

IS A DRY OR MOIST ATMOSPHERE THE MORE CONGENIAL FOR SETTING MUSCAT GRAPES?

Upon this subject many gardeners differ, the majority, however, advocating a high temperature and dry atmosphere when the Vines are in bloom; some few go to the reverse extreme by even syringing the Vines when in flower.

Consulting what I consider the nearest approach to Nature's laws in all my experiments in cross-fertilising varieties of fruit trees, flowers, and vegetables, I have had the opportunity of being in search of pollen frequently in all sorts of weather. These experiments having been made in-doors and out, during bright and sunny, dry and humid, cloudy and wet weather, I must say I have not been so sensibly convinced of the effects produced

I went on to fruit-growing, and by diligently carrying out the directions contained in M. Du Breuil's "Treatise on Arboriculture" (French edition), I have now an excellent collection of Pears. I have received 18s. a-dozen from a fruiterer in Richmond for Easter Beurré, and never less than 12s. a-dozen for those I wish to part with.

Quality, tested by actual sale, should be the object of all amateurs, and "the quality of mercy must not be strained" by such an exaction as twenty-three dozen from a young tree only 11 feet high.

When, next year, Mr. Ellis's fruit room is destitute of Beurré Clairgeau Pears—as destitute it will be—I will endeavour to supply his "ripe" wants from young and vigorous plants of about the same size, which are permitted, and rarely fail to produce, year by year, five or six dozen first-class fruit.—HENRY W. POWNALL, *St. Margaret's, Trichinopoly*.

WHAT IS A CORDON?

As an article in your last impression attempts to answer this question, and gives a definition of the term entirely at variance with the commonly accepted one in France, you will perhaps allow me to state what a cordon really means in the language of French fruit-growers generally. We know it is one of those terms that have many meanings, and hence occurs the twisting it has received of late. Clearly what we want is to know the generally accepted meaning of the term. To say, as you do, that it means any form pruned on the spur system, is quite erroneous, and so is Mr. Bréant's definition. The Peach, when trained *en cordon* in France, has its branches laid-in the same as those of trees of the larger forms. This is true of Peaches whether grown in or out of doors, the only exception being the system of Grin, in which an attempt is made to do without the nailing-in. This is adopted in but very few places, and is not liked by the French fruit-growers. For us it will prove completely useless.

You quote Professor Du Breuil. I have now the last edition of his work before me. You say he invented the term to "express certain modes of training which we have called the spur system," &c. The truth is, he invented the *form* for a purpose which he very clearly expresses. Struck with the long time it takes to cover walls with the larger forms, even when under the best management, and other difficulties and complications which he enumerates, it occurred to him that the adoption of a simpler form would be desirable. At page 329 of the very latest edition of his book (1868), he says "*Frappé de ces inconvénients nous avons cherché à y remédier en imaginant de nouvelles formes qui, beaucoup plus aisées à établir que toutes les autres, promettent de couvrir régulièrement toute la surface du mur dans un laps de temps beaucoup plus court, et fissent donner aux arbres leur produit maximum beaucoup plus tôt, sans abréger leur durée.*" These new forms he called cordons. The spurting-in of these in the case of the Pear was exactly the same as that applied to the branches of the larger forms for years before. Therefore it is quite a contortion of the author's meaning, and tends, moreover, to confuse the mind of the reader, to say that the term was introduced simply to "express what we call the spur system." I think the French language contained a name for that a long time before the Professor's appearance, and he certainly did not invent the term to supplant what they were previously known by. At page 480 of the work above quoted is a figure of the Peach *en cordon*, with the wood laid-in in the ordinary way. From the greater degree of vigour induced by the tree being confined to a single stem, the wood to be laid-in is often more profuse than from a branch of a large tree. At page 483 he even gives a figure of a very neat mode of covering a wall for cordons, and in which there is special and careful provision made for the tying-in of the young side branches of the Peach.

I, "one of the disputants," did not use the term cordon "in a very limited sense, conveying the idea that it referred only to the manner in which Apples and Pears are trained to form edgings to garden walks." I said especially that there were many forms of cordons, but that that particular one was the best for general use. With your general estimate of the cordon system I quite agree, but think you will yet find the low edging cordon excellent when well managed, and am certain that it has distinct merits for this country. Against walls, it is true, the cordons cover the space quickly from being usually confined to simple stems; but then their energies are confined too much, and, besides, the expense of planting trees so closely

together is objectionable. A better way to attain a considerable variety from a small space and cover the wall quickly, is to adopt forms with four or five ascending stems. This has been recently done on a large scale at Versailles, and with an excellent result.

By the way, I have looked through Du Breuil and other good French authors, and in none of them do I find the word cordon applied to any large form of tree; but I have just seen a very clear definition of what it is in M. C. Baltet's book on the Pear—"Le cordon est la forme réduite à sa plus simple expression; une seule tige garnie de brindilles fruitières. L'avantage du cordon est de simplifier la charpente et de réunir une collection de variétés dans un espace restreint."—(*Culture du Poirier*, p. 20.) Therefore the term cordon does apply to a particular and well-defined class of forms, and is not a particular mode of pruning, as is abundantly shown by the work of the inventor of the system, who is, I may add, the leading professor of fruit-growing in France. The French certainly do not apply the term to indicate a tree pruned on the spur system; and it is clear enough that the English have never done so. That they will adopt the term cordon in lieu of the old one is most unlikely in either case; but unless they depart widely from what is generally accepted in such matters, they must call the forms embraced under that name by the expressive term given them by their originator—a term widely accepted on the Continent.—ONE OF THE DISPUTANTS.

[We have only to repeat that M. Du Breuil uses the word "cordon" generically, and not specifically. In the edition of his book so long ago as 1846, he there defines it as "the primary ramifications of the stem, and which are generally simple;" and in his edition of 1859 he says, "The forms of this group [cordons], are all composed of horizontal, oblique, or even vertical cordons issuing directly from the stock of the tree, or supported from a stem more or less elevated." The various kinds he describes are the simple horizontal, the simple vertical, the simple oblique, the horizontal unilateral, and the palmette cordon. Of the last a figure is given which represents a tree with no less than *twenty-two* horizontal branches or cordons upon it. What is that if it is not "a large form of tree?" The quotation our correspondent has given above from M. Du Breuil is most unfairly stated, inasmuch as he quotes just enough to suit his own purpose, and then he says, "These new forms he calls cordons." Now M. Du Breuil does no such thing, as our correspondent well knows. What he does say is, "We have given to this new disposition, contrived by us for the Pear tree in 1852, the name of *cordon oblique simple*." So much for M. Du Breuil, the eminent professor.

Then there is that skilful old pruner, M. Lepère, who, after all, we believe to be the originator of the term, and not M. Du Breuil. If our correspondent will turn to his book he will find eight pages devoted to "*Palmette Peach trees with horizontal cordons*," and the text illustrated on plate v. M. Lepère's definition of cordons is, "these are the secondary branches of the Peach tree formed *en palmette*." Surely this cannot be applied to M. Baltet's cordon, which is a solitary stem, furnished with fruit-bearing *brindilles* (elongated spurs), and which has no branches at all.

M. Carrière, also, an author of note and of authority in French gardening matters says, "Particularly in arboriculture, every part of a plant trained a little horizontally is called a cordon, and on which branches are placed which are kept short by pruning, and to which the name of *branches couronnées* is given. In a handsome cordon the *coursons** are well directed, they are well displayed—that is to say, that they have no ramifications, and that they do not form what may be called bushy masses. Cordon is applied also to Pear trees, Apple trees, or any other tree when it is subjected to this form."

Our correspondent has correctly quoted M. Charles Baltet, a respectable French nurseryman, who, like himself, uses the word in its most restricted sense; his cordon being the *cordon simple* of M. Du Breuil. Whatever loose application M. C. Baltet or "the French fruit-growers generally" may make of the term, is not to the purpose; our acceptance of it is not M. Baltet's, but that of those eminent arboriculturists who for thirty years or more have devoted their attention to the inven-

* *Coursons* are in Peaches the analogues of the spurs in Pears or Apples, produced by close-pruning and pinching in the same way as spurs are. We submit this note with great diffidence to our correspondent after his authoritative assertion that our and Mr. Bréant's definitions are "quite erroneous;" but we cannot help informing him, for he does not seem to know, that the modern system of close-pruning the Peach in *branches couronnées*, including the little laying-in that is required, is totally different from the old system of "laying-in" to which we referred.

tion and perfecting of this modern system of pruning; and surely neither M. Baltet nor our correspondent will be inclined to dispute the interpretation given of the cordon by the authorities we have quoted, and by whom the term was defined and made use of before either of them could have given much or any heed to the subject.

We hold, therefore, that a cordon is a simple branch close-pruned or spurred, and not a tree, except when that tree consists of one simple branch only, and then it is a *cordon simple*, and not simply a cordon.

We will shortly furnish illustrations of the various forms of trees trained on the cordon principle.]

YUCCAS AND THEIR PROPAGATION.

I HAD lent me the other evening the last July number of THE JOURNAL OF HORTICULTURE. Mr. Robson's remarks on Yuccas (page 57), recalled to my recollection some experiments relative to these plants, which were carried out here about eight years ago. Having had no opportunity of seeing any subsequent number of the Journal, I am at a loss to know if any additional remarks have appeared in reference to their propagation. As the results of those experiments, together with my subsequent experience, do not correspond with Mr. Robson's assertion that "the Yuccas increase but slowly," I send you some particulars respecting the experiments and the results.

On each side of a long terrace walk there stood a row of overgrown, large-headed Yucca plants. Although some of them produced flower spikes almost every year, yet from having become top-heavy they never looked neat. Some were bent one way, others another, and some were propped-up. At last they became unmanageable, and were condemned, the stems being sawn through just above the surface of the soil. They were then planted, some with the stems entire, others with the stems shortened. The operation was similar to planting a post for a gate, a good ramming included.

The object of this experiment was to ascertain if the plants would grow in that state, and, if they grew, to see if they would flower more regularly. If those two points could be gained we hoped to succeed in forming dwarf, compact bushes of Yuccas, with a dozen or more spikes of bloom on each. For some time the plants were sorry-looking, and some of them were soon dressed in mourning. An occasional sneer was indulged in when the operation was going on; but now the laugh was outright. Nevertheless, some of them grew, others died, I fear from over-ramming, or careless ramming, which bruised the bark of the stems and caused them to rot. Those, however, that grew have not flowered as was expected. Since then we have put in heads of plants with naked stems more carefully, and they seldom fail to grow. The roots come out thickly all over the stem. Those that were planted so that the shoots which formed the head came in contact with the soil, in two years furnished a good supply of young plants. Some plants rooted in this way are now 3 feet high. In two or three years they will have an appearance which I consider far more effective than that which they will present after they have flowered, and have become large-headed and top-heavy.

"How do you manage to obtain so many young Yucca plants?" said a nurseryman to me one day, "I find them very slow." I then related to him the following experiment, which proved them not so slow of propagation as it would appear they are generally imagined to be.

In digging-up the roots of the plants we had sawn off, it occurred to me that they were likely to sprout if lightly covered with soil. I had, therefore, all the roots of the size of one's finger, or larger, collected, cut into lengths of 3 or 4 inches, and placed in a border, covering them with just sufficient soil to hide them. This was done in the month of May. My expectations were more than realised, for I had two and sometimes three shoots on a bit of root. We have had an abundance of Yuccas ever since. Some plants thus raised are now 2 feet high to the tips of the leaves. Even some of the very small bits that were thrown away grew, although several of them were fully exposed. Any one having an old Yucca plant can, by digging around it, and taking some of its largest roots, soon secure a supply of young plants.

The Yuccas treated as above were plants of *Y. gloriosa*; but I have two or three other sorts, and I found them quite as easy to propagate in this way. I advise those who try this

mode of propagation to place a few twigs over the roots when planted to prevent these being disturbed.—H. MILLS, *Enys, Penryn*.

REVIEW.

The Gardener's Almanack, and Poultry-Keeper's and Apiarian's Calendar for the Year 1868. Edited by G. W. JOHNSON, E. HEWITT, and T. W. WOODBURY. JOURNAL OF HORTICULTURE Office, 171, Fleet Street.

In this Almanack we have a great desideratum supplied, which is none the less valuable for its combining so much that is useful to the confraternity of gardeners, poultry-keepers, and bee-keepers, who are very often "*tres juncti in uno*." Here, under the same cover, and for the moderate price of one shilling, each and all will find much valuable information special to their separate hobbies, besides the usual information given in all good almanacks perhaps fuller than usual.

The "Gardening" calendar (if it may be so called), supplies an essay every month on such subjects as the following:—"Vines in pots," "Fuchsias," "The Oleander," "Potting and Repotting," "Melons," "Vines in a Greenhouse," "Pelargonium Cuttings," "Clerodendrons," "Roses in Pots," &c. There are also "Lists of Flowers for Amateurs," the best of each kind, with descriptions.

Then there is an essay on "Poultry-Keeping," by Mr. Hewitt, with remarks on "Prevalent Faults at Poultry Exhibitions," followed up by an admirably arranged table for memoranda for every day in the year. Here at a glance the poultry housewife can see what kind of fowl has been sat, on what number and kind of eggs, date of hatching, number of chicks, and how many reared, with a daily list of eggs laid by any and every variety of fowl. The arrangement is completeness and perfection itself.

In the Bee-keeping department we have a Calendar of Operations for every month in the year, with a blank page for each month of the busy season for the jotting-down of memoranda. The calendar is most complete and most carefully written. Whoever follows its instructions with docility can hardly fail of success. It is specially designed for the scientific bee-keeper, as we might expect from the pen of Mr. Woodbury, the first apiarian of the day; but there is matter of profitable instruction for all—learned or unlearned. There are capital illustrations of the bottle feeder and of the mode of securing and fitting combs to the frame bar.—D. & W.

METEOROLOGICAL NOTES AT LINTON PARK.

KENT, 1867.

	Rain in inches.	No. of rainy days.	No. of frosty days.
January	5.95	18	21
February	1.53	17	5
March	3.42	23	23
April	1.67	18	3
May	2.35	11	5
June	0.85	9	..
July	4.53	16	..
August	1.55	10	..
September	1.43	12	1
October	2.65	16	7
November	1.26	8	10
December	2.42	18	19
Total	26.71	176	94

The greatest fall of rain in one day was on July 26th, when 1.51 inch fell. The greatest number of consecutive dry days occurred from the 19th of June to the 2nd of July, and also from the 2nd to the 14th of November, both twelve clear days.

The hottest day was August 14th, thermometer 90°.

The coldest day was January 5th, thermometer 10°.

The readings of the barometer taken at noon each day, and, consequently, not likely to be either extreme, were as follows:—

Maximum, 30.42 inches, on March 2nd.

Minimum, 28.23 inches, on January 8th.

The winds, as taken at noon show during the year, E., thirteen days; S.E., 21; S., 80; S.W., 72; W., 46; N.W., 27; N., 59; N.E., 43; and two not determined.

As compared with former years, the rainfall of 1867 is about half an inch above the average of the preceding twelve years, and the number of rainy days nine in excess. The winds from S., and S.W., have been more prevalent, especially those from the S., while the days on which it blew from N.E. were much

fewer. The number of frosty days is about the average, and in May almost unprecedented. An early frost on September 25th reduced the period between spring and autumn frosts to exactly four months, an unusually short time. Certainly the frost of the latter period was not quickly followed by others equally sharp, but for the most delicate of out-door plants the autumn was early. *Pelargoniums*, *Gazanias*, &c., continued tolerably fresh up to the beginning of December.—J. RONSON.

ASPARAGUS CULTURE.

(Continued from page 22.)

THE second year the plants cannot be too liberally watered with liquid manure. Once every fortnight is not too often to give a good soaking, and at every alternate watering 1 lb. of salt may be dissolved in each three gallons of water. The waterings may commence in June, and end by the middle of September. Weeds ought to be removed as they appear. In autumn the stalks, when withered, should be removed by cutting them off close to the surface, and the weeds being cleared off, the beds should be forked over and the loose soil drawn off into the alleys. The beds are then to be covered with 3 inches of well-rotted manure, which by February will be considerably reduced; then soil from the alleys should be thrown out over the beds so as to cover them 2 or 3 inches thick, and the alleys are filled with half-rotten manure quite level with the beds. In March the beds are forked over, not going so deep as to injure the crowns of the plants. The alleys are to be dug, or rather trenched, so as to bury deeply the manure put into them, and when the ground is in good working order the beds are raked and made level, and the edges straightened. A dressing of salt ought then to be applied, so thickly as to render the surface white, or it may be at the rate of 1½ to 2 lbs. per square yard. This completes the second year's culture, or brings us to the end of the second year after planting.

In the third spring the Asparagus will be of a size fit to cut, but I would recommend allowing the plants to grow untouched another year, and more and finer heads will be secured. The summer culture for the third year is not different from that in the preceding season, only when the shoots are from 18 inches to 2 feet in height the weak ones are cut clean away, four to six of the strongest shoots being left on each plant. The strong shoots, having the lead, will thus attain more strength, and will keep down the weak shoots, and the beds may be gone over again early in July, removing any weak shoots that have made their appearance since the first thinning. Early in May another dressing of salt is given, and the beds are well watered with liquid manure once a fortnight.

In autumn, as soon as the ground is cleared of dead stalks and weeds, all the loose soil is drawn off the beds into the alleys, and the beds dressed with 2 or 3 inches of rotten manure. In February soil from the alleys is thrown over the beds, covering these 3 or 4 inches thick; and the alleys, which, from the removal of the soil to put over the beds, will be considerably lowered, are filled up quite level with the beds with the half-rotten manure usually found in the outsides of hotbeds. This is trenched into the alleys and left until March, when the beds are forked over, not going so deep as to injure the crowns, and the soil is well broken and made fine. The beds are then raked, drawing off a considerable portion of soil into the alleys. A dressing of salt is given, as in the preceding year, and again towards the close of the cutting. The heads will be large and fine in the fourth spring, and the beds may be said to be in full bearing.

In cutting, a little of the soil may be taken from beside the shoot with the knife (an Asparagus knife is best), which is then thrust down, but not so as to damage the crown or other shoots pushing up, and turning the edge of the knife towards the shoot, it is cut or sawn off. I prefer to cut off all shoots as they appear, when of a sufficient length—6 to 9 inches, until the end of May, unless the plants are weak, when a strong shoot is left to each plant, and this promotes root action, and is conducive to vigorous growth. Half the beds are not cut after May, and dependance is placed on these beds for the first cutting in the following spring. From the remainder of the beds the heads are cut until the 20th of June, when cutting ceases altogether, but early in the month two shoots, or at least one strong shoot, should be left to each plant, but all the others of any size are cut up to the time named.

The seasons have a great effect on the growth of Asparagus. In early seasons cutting will commence early, and in that case

it ought to be discontinued sooner than when the season is a late one. The coming-in of Peas is generally taken as the time when the cutting of Asparagus may cease; but I fear there is often more of convenience in this than any regard to the benefit of the Asparagus, and in some places where the demand is of long continuance the heads are cut later than is good for the plants. The vigour of the plants ought also to have an influence as to the time when cutting should cease, for if weak they ought to be allowed to grow early and make as much foliage as possible, thereby acquiring greater vigour for another year.

The culture in succeeding years is the same until the beds are worn out. Good culture and well-made beds at the commencement will keep Asparagus in full bearing for twenty years, and in some cases much longer; but when the beds are failing others should be made, so as to prevent a deficiency in the supply.

The mode of culture described, I may be told, is a very old one; but by it good Asparagus has been and is now grown. There are other modes of culture, which some may think I might have noticed, rather than have placed before your readers a system practised so long and so extensively; but my object has been to explain how good green or unblanched Asparagus can be grown.

I omitted stating that the dressing of manure in autumn may be of pigeon's dung, sand, and seaweed in equal quantities, or the first and last without either of the others, in place of the dressing of rotten manure; also that the shoots should be thinned early in July, leaving no more than four or six of the strongest to each plant, these only being allowed to mature.

In order to produce blanched Asparagus the preparation of the beds and planting are not different from the practice already described, nor, indeed, is there any difference until the plants are strong enough for cutting; then a quantity of sand or very light soil is placed in the alleys, and the beds are covered with it 3 inches thick. It is quite soon enough to put the sand on the beds when the heads are just peeping through the soil; and when they show through the first layer of sand, put on another and another as the Asparagus appears, until the sand is about 8 or 9 inches thick. When the Asparagus again makes its appearance cutting is commenced by drawing away the sand, and cutting the heads level with the surface of the beds, or about 8 inches long, and the sand is levelled again after each cutting. In the autumn following, the sand or light soil is drawn off into the alleys, and left until spring, when it is again used as above described. The beds have in autumn a dressing of rotten manure, and the rougher portion of the soil is raked off in spring before covering with sand.

Another mode of blanching Asparagus is to cover the beds in March to the depth of 8 or 9 inches with half-rotten leaves, the cutting taking place when the heads are just peeping through the covering, which should be carefully removed from the stems, and after cutting replaced. In autumn the leaves are drawn off into the alleys and dug in, and the beds receive a dressing of rotten manure 3 or 4 inches thick.

The plants for blanching are best grown in rows 30 inches apart, and the plants 1 foot apart in the rows. The object of blanching Asparagus is to have it white, tender, and finer-flavoured.—G. ABBEY.

NOTES FROM FRANCE AND ITALY.

Mr. Ronson, in writing on Mistletoe, stated, "It is said that it grows in the north-west of France." I may inform him that if he journey by railway from Dieppe to Rouen he will be able to see it growing abundantly on the trees on his left. I cannot tell him what the trees are, but I take them to be a kind of Poplar.

Some time ago I was making a knapsack tour in the south; and on the hills above La Grande Chartreuse, on the north side, I found a wild Dog Rose with a most remarkable perfume. I had just come from the monastery, where I had tasted the celebrated liqueur which bears its name, and I was so much struck with the strong resemblance of this Rose's perfume to that of the liqueur, that I felt satisfied (and my travelling companion was of the same opinion), that it formed an important ingredient in its manufacture. I obtained a good root, which I carried for some weeks most carefully in my sponge-bag, and brought home in a healthy growing condition, but the want of care or skill of the gardener to whom I gave it for planting, caused it to be lost. If you make this known to your

readers no doubt some of those who go that way will procure some plants for trial in this country. The climate on these hills is much the same as that of England.

In northern Italy they sometimes serve a fruit, which, though I cannot recommend it, is very pretty. I have seen it growing wild between Turin and the Sapera, and it would be highly ornamental in our greenhouses or for table decoration. The name of the plant, as I understood it, is Cicinga (pronounced *Chichinga*). When ripe both the fruit and its pod, or envelope, are of a brilliant scarlet tipped with orange. In other places I have seen another variety which is of a pale green, turning to a dusty brown when ripe. I have no doubt it would grow easily in a hothouse, or, perhaps, on a sunny border.

Again: in going down the southern slope of the Col de Tenda I found plants of a species of *Salvia* with the terminal leaves on the branches of a brilliant violet colour. Can you tell me what is its name, and if it can be procured in England?—D. S.

[The Rose, we think, is *Rosa alpina*. The Cicinga is *Physalis alkekengi*, one of the Winter Cherries. If any of our readers recognise the *Salvia* they will oblige us by sending the specific name.]

TRANSATLANTIC JOTTINGS.

AMERICAN VINES, AND PRUNUS MARITIMA AS STOCKS.

My impression is that stratified and expensive borders, defective root action, and shanking Grapes, could all be dispensed with if a few of your progressive Grape-growers could be induced to test some of our American varieties as stocks upon which to work the varieties of *Vitis vinifera*. I do not refer to grafting varieties of *Vitis vinifera* upon varieties of *astivalis* and *labrusca*, but to inarching green wood upon green wood at such a point as to prevent the possibility of the inarched variety rooting, and thereby rendering it entirely dependant upon the stock. Grafting the Vine is under all circumstances an uncertain operation, and the scion sooner or later emits roots, defeating the intention of the operator.

As stocks for varieties of *Vitis vinifera*, the varieties of *labrusca* and *astivalis* present many advantages. They are the most vigorous growers in existence, and are uninjured by heat or cold, or atmospheric changes; some ripen late and some early. It matters but little whether the roots are growing in dry or wet soil, light or heavy, drained or undrained. They are to be found flourishing under almost all circumstances in every section of the Union; battling with trees and undergrowth for root-room, and their tops clambering over the highest trees of the forest. Some varieties flourish best in swamps, their roots revelling in sour clay and water; others on hill sides, seeking nourishment among stones and gravel, where varieties of *vinifera* would starve. Those varieties that have their habitat in swamps, if removed to dry and sandy positions, grow as luxuriantly as though they were revelling in the swamp. All that is required to make varieties of *labrusca* and *astivalis* flourish, and insure healthy root action, is to give the roots work, plenty of top work, as an outlet for their vitality. Give the tops work, and the roots will extend and flourish in a wet or dry soil, in sunshine or shade, in stratified or unstratified borders where varieties of *vinifera* would languish and die. Without pruning, the varieties of *vinifera*, owing to their weak vitality, soon succumb, even if planted in good soil; on the contrary, American varieties will seek nourishment in thick undergrowth, and clamber from tree to tree, covering the tops of the highest in the forest. It is common to find them measuring from 12 to 18 inches in circumference at the surface of the ground in many portions of the Union. In one instance we measured a wild Vine 36 inches in circumference at 1 foot from the ground.

I am inclined to refer the vigour of some of the American Grapes to the formation of their roots. Those that are unaffected by mildew, and that grow luxuriantly, possess numerous small wiry roots covered with fibres. In varieties of *vinifera* the roots are large, few in number, spongy, and with but few fibres. A few days since I was much interested in an examination of over four hundred seedling Vines which I removed from their seed bed. About one-half were hybrids, and they presented a few large spongy roots, with but few fibres; on the contrary, the seedling natives of pure race possessed numerous, small, firm roots with a number of fibres. A number of our new American Grapes are liable to mildew, and upon examination I find that the roots of such are large, spongy, and with but few fibres. My impression is that the

roots of our hardy vigorous varieties have much to do with their growth, and their ability to succeed in adverse soils and situations.

If American varieties were used as stocks, but little preparation of the soil for borders would be required, and for ground vineries they would answer admirably, for they would grow luxuriantly in any common garden soil. For pot culture they would be a success, for they would flourish in a small space. I have inarched a large number of the varieties of *vinifera* upon varieties of *astivalis* with the intention of thoroughly testing their value as stocks, and, if acceptable, shall report progress in the future. Inarching the Grape has under all circumstances proved a simple and successful operation in my hands, and if I thought it would interest your readers, I would describe the process in detail.

I cannot resist the temptation of directing the attention of your readers to the advantages to be derived from using the *Prunus maritima* as a stock for Peaches, Plums, and Apricots.

Those possessing a light sandy soil experience great difficulty in cultivating the Plum, and I see no reason why their efforts should not be successful. All that is necessary is for your nurserymen to test the *Prunus maritima* as a stock. Portions of our sea-coast consist of banks of almost pure sand deposited by the waves and winds. Upon these drifts, within reach of the ocean spray, flourish the varieties of *Prunus maritima*, a dwarf-growing species, varying from 3 to 5 feet high. This year I raised a number of seedlings upon a rather heavy loam, and they made a most vigorous growth, proving that it will flourish in other soils besides sand. Although small, the fruit is excellent, and produced in immense quantities. It seems to me that this species would make an admirable stock for Peaches, Plums, and Apricots for orchard-house culture and for small gardens, more especially where the soil is so sandy as to interfere with the growth of the usual Plum stock.—ALFRESCO, Lodi, N.J., U.S. of America.

CUTTINGS OF PELARGONIUMS.

I AM pleased to have an opportunity of replying to Mr. Perkins's doubts in regard to my method of propagating the Pelargonium. I held for years the same opinion that Mr. Perkins holds, and it was only after seeing the success that attended the efforts of a first-class propagator in a large London nursery, that I felt so thoroughly convinced that the close plan was so advantageous. At first I was careful to only adopt it in a modified form, but I soon saw the full force of keeping the cuttings close, and I only advise Mr. Perkins to give the system a fair trial, when, I think, he will bear out the greater part of what I have stated.

In regard to the number of cuttings I lose per thousand, I may say that the loss is very small indeed in most cases. Of Lady Plymouth, although it is generally considered to be difficult to root, I find on the close system I do not lose twenty cuttings, and it strikes as soon as Tom Thumb or any of the strong growers, of which I may also state that I do not lose a larger per-centage. The varieties most liable to damp-off with me are the Silver-variegated Zonals, if not looked carefully after, in about a week or ten days after the cuttings are put in, on account of the lower leaves decaying. The varieties of the Golden section all do remarkably well, the loss being small, not exceeding from twenty to thirty per thousand.

I would observe, that immediately after you find the cuttings rooted commence giving air, or damping-off will soon take place.

Mr. Perkins says that my mode of treatment may do very well where the coal heap can be run to. Here I differ from him; for I have found by experience that, although the cuttings are put in later, they strike so much faster, that before the winter sets in there is ample time to harden them off, so as to enable them to withstand the dull and trying weather we are experiencing at the present time.

I beg to thank Mr. Perkins for commenting on my method, and trust that he and numbers of the readers of the Journal may see their way clearly to the adopting of my plan.—JAMES STEWART, Nancham Park.

TEA CULTURE IN INDIA.—To those interested in the cultivation of Tea in India the following information may prove satisfactory:—In a letter just received from one of my sons in Assam, he states that in his garden the plough is being used

with the best results; it is drawn by bullocks, and he says the work done is quite as good as by the hoe, and the expense trifling. I have four sons in Assam, three of whom are Tea planters. I am a great believer in the cultivation of Tea in India.—OBSERVER.

SHRUBS FOR GAME COVERTS.

REFERRING to the inquiries relative to Game coverts and injury to plants, I can state from twenty-five years' experience, and with game of all sorts up to my doors, that hares and rabbits will destroy any sort of trees or shrubs when young, except the Rhododendron, Box, Privet, and Bramble; that I can now rear a young plantation on any part of my property only by surrounding it with wire netting, and cannot enclose a field except with timber or wire fencing; and that I have frequently known Ash trees as thick as a man's thigh totally ruined in spring by the hares and rabbits, though a corn field was in braid close to the covert, they appearing not to feed upon the bark, but to do the mischief merely for amusement's sake.

The plants mentioned I have had well tested, and never saw them injured; and no shrubs form a better or more beautiful covert, or grow more freely on fairly good, rather dry, loamy soil.

The Bramble will grow under trees, close along the ground, or as high as a man's knee, retaining its leaves all winter; the Rhododendron will grow close to the ground, affording an excellent low cover, and seldom rising above 8 feet, flowering beautifully every summer; the Privet will shoot up to 10 feet, keep its green leaves far into spring, and flower very sweetly in summer; whilst the Box will grow 25 feet high, is very beautiful, and the wood of great value.

If a friend were to ask me how to make a game covert in his park, I would recommend him either of the following two methods:—

1st, Plough all parts possible in September or October: sow and barrow-in early in spring plenty of Bramble seed, Barley, or Beans (the two latter for winged game in autumn); plant on the same ground Silver and Scotch Fir, Oak, Hazel, and Privet, in equal portions, 4 feet apart; surround the whole for six years with wire netting, and thin-out liberally every three years.

2nd, Plant and sow as above mentioned, with the exception of the Bramble; and plant early in spring on the same ground Box, Rhododendron, and Privet, but no trees or rabbit net required.

Of course all must be well fenced from cattle, and rides may be left, or cut out afterwards. The plants should not be much dug about, as their roots are tender; but the grass in July should be torn up round them to prevent smothering.

Any one who has in his park five or six such coverts, of about five acres each, is much to be envied, and he will find it pay much better than deer.—W. G.

GRAFTING AND INARCHING VINES.

I CAN fully confirm what Mr. Douglas says (page 25), about the inutility of inarching the Red Frontignan on the Black Hamburgh. A branch in my viney so treated shrank this year even more than the parent plant.

As to the Chasselas Musqué, I fear that no stock will prevent its cracking, for this cracking seems to arise from the texture of the flesh and skin, which are impatient of moisture during the final swelling-off, particularly if the temperature be low. The same takes place in Green Gages against a wall when a wet and cold August succeeds a dry July. The Chasselas Musqué is so unequalled in point of flavour, unless, perhaps, by an unusually well-ripened Muscat of Alexandria, that one is loth to dismiss it from one's collection. It has been recommended to thin the Grapes severely; but as the effect of thinning is to increase the size of the berries, and as the largest berries are always the first to split, I should rather recommend that this variety be thinned less than others. If the roots were so confined that they could not obtain any water except at the will of the cultivator, if moisture were liberally supplied during the growing season, and withheld during the ripening period, with sufficient air and warmth I think few berries, if any, would crack.

I wish I could hit upon any plan which would, with any

probability of success, prevent the shanking of Frontignans. Is it true that they never shank against an open wall?—G. S.

POTATO PRODUCE—INFLUENCE OF THE SETS.

THE following are the results obtained by Mr. May, of Benthall, near Broseley, from experiments made in the year 1865 on 129 trial plots. He endeavoured to ascertain—

Firstly, The influence of the size of the set on the economic results of the crop—*i.e.*, whether any increase, and to what extent, is obtained over and above the extra weight of the set, in the planting of large, in lieu of small, sets.

Secondly, The influence on the crop of the distance at which the sets are planted; or the results of close and wide planting of various sized Potatoes.

Thirdly, The comparative results from planting similar weights of large and of small Potatoes per acre.

Fourthly, The relative advantages of cut and whole sets.

Fifthly, The influence of thick and thin planting, and of the size of the set on the proportion borne between the weights of the sets and the weight of the crop, and the rate of increase under various conditions.

Sixthly, The relative productiveness of different varieties of Potato.

Much diversity of opinion seems to prevail in these points, which are of economical importance in relation to both the farm and garden cultivation of the crop.

The selection of the Potato sets appears commonly to be more a matter of present expediency than prospective profit. The general course is to appropriate the largest for use, the very smallest for pig-feeding, the tubers of intermediate size being preserved for replanting; this method of assortment results in the use of sets of from 2 to 3 ozs. in weight, and a set of less than 2 ozs. is as often planted as one exceeding 3 or 4 ozs.

Our primary question is, whether an increase in the size of the set will produce an excess above the extra weight of the sets planted; such extra weight going to increase the strength of the individual sets without increasing their number.

The unequivocal results in favour of large sets, obtained from my experiments carried out in 1864, as well as from those which form the subject of this report, induce me to describe carefully the conditions under which the experiments were conducted.

Every precaution was taken to ensure the most perfect uniformity in the conditions under which the various experiments were made. The manure was separately weighed out, and distributed on each 20 superficial feet of ground. The distance (2 feet) between the rows was the same throughout the trial ground; and to counteract the influence of any slight variations in the character of the soil, the particular experiments that would be brought into immediate comparison were placed as nearly as possible in juxtaposition. External rows were rejected for the experiments, and planted with part of the ordinary crop; and every individual set was separately weighed and selected to the specified size, and planted to measure, at precise distances.

The gross average return per acre of numerous varieties was from—

	Tons.	cwts.	qrs.	lbs.
1 oz. sets	10	13	3	17
2 oz. sets	12	15	2	15
4 oz. sets	13	9	0	2
6 oz. sets	16	13	1	16
8 oz. sets	18	11	0	16

The following are the amounts of nett profit per acre for each ounce in the increase in the weight of the sets from 1 oz. up to 8 ozs. (each ounce in the weight of the set occupying 2 square feet, being equivalent to 12 cwt. 17½ lbs. per acre) of seed:—

	Tons.	cwts.	qrs.	lbs.
From 1 to 2 oz.	1	13	2	7½
" 2 to 4 oz. for each extra oz.	0	18	3	14
" 4 to 6 oz.	1	12	0	21
" 6 to 8 oz.	0	18	3	14

The average of a number of experiments with different varieties planted 9 inches apart in rows gave very similar results, as follows:—

GROSS RETURNS PER ACRE.				
	Tons.	cwts.	qrs.	lbs.
1 oz. sets	10	12	0	23 or 14.21 per set.
2 oz. sets	15	2	2	11 or 18.45 "
4 oz. sets	17	17	3	12 or 21.99 "

After deducting the weight of the sets, the nett balances of produce per acre stand thus:—

	Tons.	cwts.	qrs.	lbs.	ozs.
1 oz. sets.....	9	16	0	0	or 13.21 per set.
2 oz. sets.....	13	10	0	21	or 16.45 "
4 oz. sets.....	14	13	0	4	or 17.99 "

The average produce of a number of varieties planted at intervals of 6 inches in the row also exhibited similar advantages in favour of the larger sets, viz.:—

	Tons.	cwts.	qrs.	lbs.	ozs.
1 oz. sets.....	13	4	1	20	or 10.85 per set.
2 oz. sets.....	15	19	0	12	or 13.15 "
4 oz. sets.....	22	0	2	3	or 18.11 "

After deducting the weight of the sets, the nett balances of produce per acre stand thus:—

	Tons.	cwts.	qrs.	lbs.	ozs.
1 oz. sets.....	12	0	0	13½	or 9.45 per set.
2 oz. sets.....	13	10	1	27	or 11.15 "
4 oz. sets.....	17	3	1	5	or 14.11 "

Every step in each of these three series of experiments gives, without an exception, unequivocal evidence that each increase in the weight of the set produces more than a corresponding increase in the weight of the crop. The following statement will, however, show that the advantage in the employment of large sets is much less striking in the early than in the late varieties; out of the examples before given, the average produce of the early varieties, planted 1 foot apart in the row, exhibit the following result:—

	Gross Crop.					Nett.				
	Tons.	cwts.	qrs.	lbs.	ozs.	Tons.	cwts.	qrs.	lbs.	ozs.
1 oz. sets.....	9	3	3	26	8	11	3	8½
2 oz. sets.....	10	14	2	17	9	10	1	10½
4 oz. sets.....	13	19	0	7½	11	16	1	22½
6 oz. sets.....	15	6	0	22	11	13	1	2½
8 oz. sets.....	7	17	0	21	2	19	5	23

Although there is throughout an increase over and above the extra weight of the sets, the advance between the larger sizes is not very marked, and is much below that wherein the early and late sets are averaged together. There is even a falling-off in the produce of the 8 oz. sets, in comparison with those weighing 6 ozs.; but this is partly from accidental circumstances, the 8 oz. sets being much sprouted before planting; indeed all the larger sets of the early varieties were much more advanced than those of smaller size. After separating the early sorts from the general average results of early and late, the average produce of the late varieties, taken separately, will stand as follows:—

	Gross Crop.					Nett.				
	Tons.	cwts.	qrs.	lbs.	ozs.	Tons.	cwts.	qrs.	lbs.	ozs.
1 oz. sets.....	12	0	0	15	11	7	3	26
2 oz. sets.....	15	3	1	19	13	19	0	13
4 oz. sets.....	17	16	0	24	15	7	2	11
6 oz. sets.....	30	6	2	11	26	13	2	19
8 oz. sets.....	31	3	3	24	26	6	2	26

To establish the influence on the crop of the distance at which the sets are planted, I shall compare, separately, each series of experiments on Potatoes of the same weight, planted at different distances:—

AVERAGES OF 1 OZ. SETS.										
Varieties.	Distance apart.	Tons.	cwts.	qrs.	lbs.	Tons.	cwts.	qrs.	lbs.	ozs.
13	1 foot.....	10	9	3	17	..	9	17	3	0
11	9 in.....	10	12	0	23	..	9	16	0	0
11	6 in.....	13	4	1	20	..	12	0	0	13

AVERAGES OF 2 OZ. SETS.										
	Distance apart.	Tons.	cwts.	qrs.	lbs.	Tons.	cwts.	qrs.	lbs.	ozs.
13	1 foot.....	12	15	2	4	..	11	11	1	7
12	9 in.....	15	15	2	11	..	13	10	0	21
10	6 in.....	15	19	0	12	..	13	10	1	27

AVERAGES OF 4 OZ. SETS.										
	Distance apart.	Tons.	cwts.	qrs.	lbs.	Tons.	cwts.	qrs.	lbs.	ozs.
12	1 foot.....	15	17	2	15½	..	13	9	0	2½
6	9 in.....	17	17	3	12	..	14	13	0	4
3	6 in.....	22	0	2	3	..	17	3	1	5

AVERAGES OF 4 OZ. SETS (SIMILAR VARIETIES).										
	Distance apart.	Tons.	cwts.	qrs.	lbs.	Tons.	cwts.	qrs.	lbs.	ozs.
3	1 foot.....	15	8	3	24	..	13	0	1	11
3	9 in.....	15	19	2	14	..	12	14	3	6
3	6 in.....	22	0	2	3	..	17	3	1	5

These comparisons all show an advantage in planting the smaller sets at intervals closer than 12 inches in the rows; but the results are not very decided, and in one or two cases the gain in the gross crop does not make up for the extra weight of the sets planted.

The following comparisons refer to the effect of planting the sets more than a foot apart in the rows:—

Three experiments averaged together—viz., Eight-ounce Flukes, six-ounce Flukes, and four-ounce Late Red, gave a gross crop of 23 tons 16 cwts. 1 qr. 8 lbs., and a nett average of

20 tons 3 cwts. 1 qr. 17 lbs. The same sizes and varieties, planted at intervals in the rows of 1 foot 3 inches, produced a gross crop of 18 tons 13 cwts. 1 qr. 2 lbs., and a nett crop of 15 tons 14 cwts. 3 qrs. 20 lbs.—a falling-off of 4 tons 8 cwts. 1 qr. 25 lbs. per acre. Indeed, the produce of each set was as nearly as possible the same, whether planted a foot apart or 15 inches, so that the additional distance was so much lost to the crop. The average produce of six-ounce and eight-ounce Flukes shows a similar falling-off when planted more than a foot apart in the rows. The nett average produce per acre was:—

	Tons.	cwts.	qrs.	lbs.
Flukes, at 1 foot.....	17	10	1	25
" at 1 foot 3 in.....	15	8	2	6½
" at 1 foot 6 in.....	12	16	0	5

This diminution of the crop, through reducing the number of the sets per acre, is remarkably uniform, and as nearly as possible proportionate to the distance at which the sets are planted.

The general tenor of these experiments points to an interval of 10 or 12 inches in the rows as being the most profitable distance at which to plant large, full-sized Potatoes, of from 4 to 8 ozs. in weight. A moderate increase in the nett crop may be expected from still further diminishing the distance when the sets are below 4 ozs. in weight.

The general bearing of the results obtained is:—

Firstly, Every increase in the size of the set, from 1 oz. up to 8 ozs. in weight, produces an increase in the crop much greater than the additional weight of the set planted. The nett profit, over and above the extra weight of the sets, in planting four-ounce sets in lieu of one-ounce sets, amounted, on the whole series of experiments, to between 3 and 4 tons per acre; and the further profit, on the increase of the size of the set from 4 ozs. to 8 ozs., averaged about 5 tons an acre; all the intermediate steps partaking proportionately of the increase.

Secondly, The advantages in favour of the large sets is more marked in the late than in the early varieties.

Thirdly, In the use of small sets, of from 1 oz. to 3 ozs. in weight, a larger balance over and above the weight of the sets was obtained by planting from 6 to 9 inches apart in the rows than at wider intervals.

Fourthly, Increasing the intervals at which sets are planted, even of the largest size, in the rows, to more than 12 inches, diminishes the crop; and the wider intervals induce no increase in the weight of the produce of the individual sets.

Fifthly, It may be broadly stated that the weight of the crop is proportionate to the weight per acre of the sets, and that small sets will produce the same crop as an equal weight per acre of large sets. The fact is, however, of limited application, as a weight of very small sets equal to a weight of full-sized Potatoes could not be got into the ground, except by planting them so closely as to be prejudicial to the crop. The advantage, therefore, of large sets remains practically unimpaired.

Sixthly, Weight for weight, cut sets produce, as nearly as possible, the same weight per acre as whole Potatoes; but for the reasons given above, the weight of the sets should not be reduced by subdivision.

Seventhly, Smaller sets give a larger produce, in proportion to their weight, than the larger sets.

Eighthly, When the intervals between the sets in the rows are diminished to less than a foot, the produce of each individual set is proportionately diminished. Though this is not necessarily accompanied by a diminution of the weight of the crop, no increase in the produce of each individual set is caused by placing the sets at intervals wider than a foot.

Ninthly, With reference to the relative produce of different varieties, a late red sort takes the precedence throughout the experiments; and of the several varieties of Fluke, Spencer's King of Flukes and The Queen of Flukes are much more prolific than the ordinary variety.—(*Journal of Royal Agricultural Society.*)

FRUIT-GROWING IN THE FAR NORTH.

As we are now in the midst of our planting season, with the time for propagating or grafting fast approaching, it may be interesting to your readers to learn what sorts of fruits succeed so far north as the shores of the Moray Firth, in Scotland.

Although our climate is so dry and sunny as to make Wheat our staple crop, yet varieties of fruits that succeed here must be endowed with a certain degree of hardiness. We have had a rather extensive collection here for the last thirty years, and

profiting by our experience, some of your readers may avoid the disappointment attending experiments in growing new fruits. Those that succeed best here may reasonably be expected to do well further south.

A great hindrance to the growth of good fruit in Scotland and in the north of England, is the uncertainty and disappointment occasioned by planting varieties unsuited to the climate.

As Pears and Plums are the two sorts of fruit that have of late received the most important additions of improved varieties, I shall for the present confine myself to these.

The first-rate Pears that succeed on the wall here are—Jargonelle, ripe in August and September; Sinclair, in October; Marie Louise, Thompson's, Beurré Superfin, Beurré Hardy, Van Mons Léon Leclerc, and Brown Beurré, in November; Winter Nelis and Hacon's Incomparable, in December and January; Easter Beurré, in February and March; Beurré de Rance, in March and April; Fortunée, in April. Citron des Carmes, ripening in July, a good second-class Pear, is a desirable addition to the foregoing.

The following are first-class as standards—viz.,—Beurré d'Amanlis Panaché and Sinclair, ripe in October; Beurré Superfin and Aston Town, in November; Zéphirin Grégoire and Beurré d'Arenberg, in December and January; Monarch and Beurré de Rance, from February to April. These have not yet borne abundantly.

Good and useful second-class Pears as standards are—Summer Doyenné, ripe in August; Beurré Giffard, in September; Williams' Bon Chrétien, in October; Muirfowl's Egg, in November; Achan, in December; Forelle, in January; and Léon Leclerc de Laval, an excellent baking Pear, from November to May.

Some of the varieties that do not succeed well here are—Passe Colmar and Beurré Bosc, hardly first-rate; Louise Bonne, Urbaniste, Fondante d'Automne, Glou Morceau, Dunmore, Joséphine de Malines, and Bergamotte d'Esperen, all second-rate; Flemish Beauty and Duchesse d'Angoulême, third-rate; Chaumontel, Beurré de Capiaumont, and Suffolk Thorn, fourth-rate. Some newer famed varieties have not yet fruited.

Of Plums—July Green Gage, Jefferson, Bryanston Gage, and Reine Claude de Bavay, are first-rate wall fruits. Coe's Golden Drop is the best, but drops the greater portion of its fruit when quite small.

Belgian Purple, Denniston's Superb, and Lawson's Golden Gage are abundant-bearing, first-rate standard Plums.—JOHN McCULLOCH, *Gardener, Duffus, near Elgin.*

WOOLLAND HOUSE, DORSET.

THE SEAT OF MONTAGU WILLIAMS, ESQ.

TO-DAY, January 6th, I visited my friend and neighbour, the frost being hard, and the ground lightly covered with snow—not a very favourable time for a review.

The house is a fine mansion, commanding a magnificent northern view of the grassy vale of Blackmoor for many miles. It is situated under the same range of hills as my own house. The views from the hills behind our houses is, perhaps, one of the finest in England. I have never seen anything to equal them, except the Weald of Kent, from the windows of Horsmonden rectory, the property of the Rev. Hugh Marriott.

On the west side of the house is a new church built by Mr. Williams, capable of holding the few parishioners and the household. It is quite a model of its kind. In front of the house is a lake stocked with carp, tench, and other fish. I was asked to look over the gardens. Of course, with snow on the ground, it was not a very propitious time; but I saw one or two matters of public interest, which are the main object of this article.

I saw a galvanised wire trellis for Peaches, Nectarines, and other wall fruit. I think in process of time of copying this. Mr. Williams told me that it answered admirably. It is well put up, the wires being 6 inches apart, and strained so as to fit closely to the walls. There is no need of nails or nail holes, the habitats of woodlice, earwigs, and other pests.

The other subject of interest were specimens of Hullett's Chinese Sugar Grass, hung up in theinery. I refer to this (see page 14), in compliance with the wishes of "H. C. S. G." Mr. Williams pointed them out to me, and said, "These are the famous Sugar Grasses you have lately heard so much about. I had ten seeds, which cost me 2s. Of these, three did not come up, seven came up, two were cut off by the frosts, two grew 5 feet high, and three grew 10 feet high. The seeds, which

amounted to about five hundred per stalk, did not ripen, as I planted them two months after the prescribed time." This is all he could tell me about it.—W. F. RADCLIFFE.

[Unless the Chinese Sugar Grass is sown in a hotbed, and the seedlings planted out, no seed is ripened by the plants in this country, nor even then except in favourable localities.—EDS.]

HABITATS OF THE MISTLETOE.

I HAVE a plant of it here from seed sown on an Apple tree, and now it is a bush about 9 feet in diameter. There are a few more in Ireland, but none growing naturally.

In France, the orchards one passes on the way from Calais to Amiens are loaded with Mistletoe. In the south of France it abounds on the trees about Pau, chiefly on Poplars. I have not seen it on the Oak; but in the Pyrenees near Gabas I have observed the Silver Fir loaded with it. It is also stated that it grows most abundantly on *Pinus sylvestris* in the forests of Germany, about Magdeburg. Query, Does it really live on the sap of the tree, or only attach itself as a barnacle does to the rock? The Apple tree on which mine hangs seems evidently exhausted, as if by supplying its food; but, then, is it not extraordinary that the same plant should live upon the sweet sap of the Apple and Poplar, and on the resin of the Pine tribe? The analysis of the Mistletoe (French *Gai*), from such different species of trees would be curious.—C. W. H., *Hamwood.*

KITCHEN GARDEN WALLS.

(Continued from page 10.)

GARDEN walls are usually 9 inches, 14 inches, and 18 inches in thickness. The thickness of a wall should be in proportion to its height. A wall between 6 and 8 feet in height will, providing the workmanship is good, prove secure if one brick or 9 inches in thickness; but if the height exceed 8 feet, piers will be needed. A 9 inch brick wall 9 or 10 feet in height should have piers 22½ inches, or two stretchers and one header, in breadth, and the piers should be 12 feet apart. They should proceed from the foundation and be carried up to within 2 feet of the top of the wall or coping. They ought not to project more than half a brick, or 4½ inches, from the wall. It is well to have a coping on the tops of the piers. A 9-inch wall supported by piers is unsightly, the trees are difficult to train upon it, and they succeed better upon walls unshaded by piers. In constructing the wall the piers may, indeed ought to be built on the less important side, so that the more desirable aspect may present a plane surface for the training of the trees.

A wall 14 inches in thickness is very substantial, and may be carried up to a height of 12 feet without the support of piers. Walls 14 inches thick are unobjectionable, and are as strong as will be necessary in most instances; but in particular cases, as in bleak and exposed situations, where walls are required of a greater height than 12 feet above the ground level, a wall 18 inches in thickness will be much more secure. The thicknesses I would recommend, are for walls not exceeding 8 feet in height, 9 inches; 9 feet and not exceeding 12 feet, 14 inches; and 12 feet and not exceeding 18 feet, 18 inches; and in all cases I would do without brick piers, which are unsightly.

A wall 14 inches thick built hollow will be found quite as substantial as a 14-inch solid wall, whilst an 18-inch hollow wall is stronger than a 14-inch solid wall. Hollow walls are drier and warmer than those which are solid, and being fully as durable ought to supersede these entirely, more particularly those built 9 inches thick, with piers.

All walls, more particularly garden walls, ought to have good foundations; in all cases these should be the depth of the borders, so that in trenching these the foundations may not be undermined, or the soil loosened. If the bottom of the trench is firm it will not require to be concreted, but if soft it may be necessary to concrete it, if not its full length, at least in some places where the ground is soft. In such places the trench should be of a greater depth than where the bottom is firm, and be filled to the level of the firm bottom with concrete, which may consist of coarse gravel run with mortar. Ram this quite firm, and then put on a layer of fine gravel. The bottom ought to be made quite level, and if the ground slope proceed by horizontal steps, short or long, according to the incline of the ground. The bottom of the trench should exceed in width the thickness of the wall, for the base of this must be twice the thickness of the wall, or have two "sets-on,"

on each side. A 9-inch wall will need an 18-inch base, a 14-inch wall one of 22½ inches, and an 18-inch wall a base of 27 inches. When the ground is very firm, one-half of the above breadths of base will do; but in places where stone is procurable the base may be of that material, commencing with the width of base required for the wall, and battering both sides of the wall upwards, so that at the ground level the thickness will be that of the wall to be built. This is a great saving of bricks, and affords a foundation quite as substantial as these, if not more so. Stone, however, cannot always be had, or its costliness is an objection to its use.

Figs. 1, 2, and 3 are sections showing different modes of forming the foundations of garden walls.

It will not be necessary to give further sections, as it will be evident from those given, that the foundation or base should project 4½ inches beyond both faces of the wall whatever its thickness may be. In some cases, as where the ground is soft, a wider base may be desirable; then the base may be twice the thickness of the wall, diminishing the width by equal steps on both sides, each step or "set-on" not exceeding 2½ inches.

Sometimes stone is plentiful, but not of a description suitable for forming a good face or convenient courses for training. To economise bricks, I have seen walls with stone bases to the ground line, and the less important side of the wall built of stone, the other being cased with 4½-inch brickwork, and they were very substantial. The bricks (headers), should be well bonded with the stone, and the stone with the bricks.

Stone walls are necessarily of greater thickness than those of brick, and it is customary to incline them upwards on both sides so as to be wider at the base than the top; for instance,

Fig. 1.—Section of a 9-inch Wall without Piers.

Fig. 2.—Section of a 9-inch Wall through Pier, the dotted upright line showing the line of 9-inch wall.

Fig. 3.—Section of 18-inch Wall, with a stone base from foundation to the ground line.

a wall 6 feet 6 inches high is made 20 inches thick at the bottom, and reduced to 15 inches thick at the top; one 10 feet high is made 24 inches thick at the bottom, and reduced to 16 inches at top. A stone wall from 12 to 15 feet in height needs a base of 28 inches.

I have not noticed banded and other descriptions of bricks by which it is said that the necessity for nailing is obviated. My experience of them is very limited, and I am not prepared to give an opinion, only I do not like their projecting and affording an uneven instead of a plane surface. The process of tying, also, is more tedious than that of nailing.

I may here likewise state, that there is no objection to a stone wall, however uneven the courses, provided it be covered with a trellis of No. 10 galvanised iron wire. The wires should be fixed horizontally, from 3 to 4½ inches apart, being passed through holdfasts entering the wall about 2 inches, and projecting from three-quarters of an inch to an inch, so that the wires may be about half an inch from the wall. There must be an iron plate at each end of the wall, through small projecting

eyes in which the wires can be run and fastened, straining them at one or both ends according to the length of the wall. The plates, therefore, ought to be made secure to the wall, and to maintain the wires equidistant the holdfasts should be put in 3 feet apart, or as near that distance as the joints in the wall will permit. The appearance is good, the trees thrive well against the trellis, the wall is not damaged by nailing, and the wires are very durable. I know some iron trellises which have been fixed nearly half a century, and are still almost as good as ever. Wood trellises are heavy, quite as expensive as iron, and not half so durable. I have taken them away quite useless not twenty years after they had been erected.

In constructing garden walls, good brick, or good durable stones of a suitable thickness, are essential, and not less important is good mortar in which to set or lay them. The quality and quantity of lime has a great influence on the firmness of the work. Good lime, such as plasterers use for "running" to make "putty," is unquestionably the best for all descriptions of brickwork, whilst for stone walls a hotter description of lime will make better work. As to sand, it should be sharp, in order to become hard when blended with the lime, but for garden walls it may be too sharp; hence river sand is not good, nor pit sand approaching to gravel, but rather sharp pit sand of a loamy nature. Two tons of sand and one ton of lime make very good mortar, setting sufficiently hard for garden walls. Cement, or the addition of any hard-setting material should be avoided, as it is almost impossible to drive nails into it.

Not only should good materials be employed, but these must be properly disposed in building. The work ought not only to have an even or plane surface, be plumb, but the bricks should be well bonded. There is no question that the Flemish bond is

Fig. 4.—9-inch Wall, Flemish bond. 1st course.

preferable to English bond. In Flemish bond the headers, *a*, are laid alternately with the stretchers, *b*, in the 1st course (fig. 4), and in the 2nd course (fig. 5), where *c* is a stretcher and *d* a

Fig. 5.—9-inch Wall, Flemish bond. 2nd course.

header; whilst in English bond (figs. 6 and 7), the courses are alternately one of headers and another of stretchers throughout, as *e* stretchers, *f* headers. Sometimes in English bond the

Fig. 6.—9-inch Wall, English bond. 1st course.

headers are put in alternate courses with the stretchers, but in general four courses of stretchers are laid to one of

Fig. 7.—9-inch Wall, English bond. 2nd course.

headers, but the work is not so good as when the courses are alternately headers and stretchers.

To make good work of a 9-inch wall, the bricks must be of uniform size—usually 9 inches long by 4½ inches in breadth,

Fig. 8.—11-inch Wall, Flemish bond. 1st course.

and scarcely 3 inches in thickness. If the bricks are fully 4½ inches in breadth and scarcely 9 inches in length, no brick-layer can make good work with a 9-inch wall, as the stretcher course will prove too wide for the header course; hence the surface will be in and out, and the joints irregular and bad. In walls of greater thickness than 9 inches, the irregularity in

the dimensions of the bricks can to a certain extent be accommodated, but where good work is wanted the bricks cannot be too regular in size.

In constructing 14-inch walls in Flemish bond, on one side a half brick must be used for a header, whilst on the other side a whole brick is laid (see *fig. 8*). In the next course (*fig. 9*), the headers are reversed, so that they will lie on the course of headers on the other side, and the third course (*fig. 10*), is laid with whole headers in place of half headers. The headers are

Fig. 9.—14-inch Wall, Flemish bond. 2nd course.

made to cross the internal as well as external stretchers, and there will be a thorough bonding of the work, but it is at the expense of putting two courses on the same side of the wall

Fig. 10.—14-inch Wall, Flemish bond. 3rd course.

with half bricks for headers. The headers in the next course will cross the headers in the third course, and so on. If the headers are carried up perpendicularly, the wall will have a neater appearance than it would have if it were built in English

Fig. 11.—14-inch Wall, English bond. 1st course.

bond, examples of the courses of which are shown in *figs. 11* and *12*. In this mode of building the headers are laid in alternate courses, with first a row of headers and then a row of stretchers, there being a row of headers on one side, and a row of

Fig. 12.—14-inch Wall, English bond. 2nd course.

of stretchers in every course. This makes a very good bond; but in ordinary building it is not usual to lay a row of headers upon every course of stretchers, but to put four courses of stretchers and then a row of headers, which is not so tedious to build, but the work is not so good.

Hollow walls are built both in Flemish and English bond,

Fig. 13.—14-inch Hollow Wall. 1st course.

but the former is much preferable, hence it is the only kind of hollow wall which I shall describe. As in the case of a 14-inch solid wall, the headers and stretchers are laid alternately, the first header on one side being a whole brick, and all the others

Fig. 14.—14-inch Hollow Wall. 2nd course.

half bricks, except every fifth header, which is a whole brick. (See *figs. 13* and *14*.) On the other side of the wall the third header is a whole brick, and then every fifth afterwards, so that every third header is a full-length header, but on opposite sides of the wall; all the other headers are half bricks. The hollow part may begin at the ground line, the wall being built solid up to that, and then carried up hollow to within three or

four courses of the top, which should be built solid the same as the base, as shown in *fig. 15*.

It is desirable that the joints in all brickwork should be small; indeed, they cannot be worked too closely; that the horizontal joints should be on one level, which will be the case if the bricks are laid on an even bed of mortar; and that the perpendicular joints in Flemish bond should not only cross but be quite perpendicular, though separated from those above or below by stretchers.

Walls are best built in mild weather, for should the nights prove severe the mortar will, to a certain extent, fall out from the joints on a thaw taking place, whilst if built in very wet weather, heavy rains beating against the new brickwork cause the mortar to run, giving the wall an unsightly appearance. In building in dry weather the bricks absorb the water from the mortar too quickly, consequently good work is not then made, unless the bricks are well sprinkled with water.

Good pointing is essential to a good wall, and the bricks should be so bedded that it will not be necessary to force any mortar in, but simply to dress the joints off with the trowel. Fancy pointing is not required for garden walls, unless under peculiar circumstances, and where a wire trellis is to be fixed; for nailing soon spoils the appearance of a "dressed-off" wall.

Having now referred to most of the essentials for a garden wall, I will next notice copings. There is, perhaps, nothing equal to stone for copings, where it can be had at a moderate cost. I have seen three kinds of coping employed, the V, the flat, and the dished, each having its advocates, but I have no doubt as to the dished being the best. However, as tastes may differ, I give examples of the three.

Fig. 16, is a high V-coping 18 ins. in breadth, 6 inches in depth in the centre, and 1 inch at the edges. This is too high in the centre for garden walls, unless they are required to be ornamental.

Fig. 17, is a low V-coping 18 ins. in breadth, 4 inches in depth in the centre, and 1 inch at the edges. Both this and the preceding have a small groove or throating beneath on both sides, to prevent the drip running down the wall.

Fig. 16.

Fig. 17.

Fig. 18.

Fig. 18 represents a flat coping 18 inches in breadth, and 1 inches in depth on one side, and 3 inches on the other, so that water may run off. On the lower side there is a groove beneath the projection.

Fig. 19 is a dished coping, the stone being 4 inches thick, and dished-out in the centre 1 inch, having an incline from the centre inwards, and also longitudinally along the wall or coping, so that water will not only run from the sides to the centre but along the wall; the channel, beginning at level, will at 12 feet be 1 inch in depth, and it should incline both ways. At every 12 feet there should be a pipe to convey the water away, consequently there will be no drip.

Fig. 19.

Fig. 15.

The copings represented are for 14-inch walls, having a two-inch projection on each side beyond the surface of the wall, which will be ample. Greater widths are unsightly, and prevent the trees receiving the benefit of rains and dews in summer.

Next to stone copings those of fire clay are good. They should be 3 inches thick, have a groove on one side, and be set so as to incline to the side on which the groove is situated, which should be the north side of a south-aspect wall, or the east of an east or west wall. The copings, of whatever kind they are, ought to be put on when the wall is built, so as to protect the latter from the weather, and the joints should be made good with cement, so that water cannot enter the wall by the joints of the coping.

For particulars as to the construction of flued walls, see Vol. X., New Series, pages 429, 430, and 431, where I have stated all I know about them.—G. ABBEY.

NOTES AND GLEANINGS.

It was only last week that one of our correspondents, in writing of *Dracanas*, entered into some particulars respecting the great DRAGON TREE (*Dracena draco*), at Oratava, in the island of Teneriffe. The news has just reached this country that its immense head, which has withstood the tempests of many hundreds of years, was levelled to the ground by a storm which occurred last autumn. The gentleman who reports this loss states that when he saw the tree in February last it was in excellent health, and its immense crown was covered with innumerable panicles of scarlet fruit, though the trunk was completely decayed in the interior. A solid wall had been built under a portion of the trunk where the ground is sloping, and some of the branches were propped, but, it would seem, very inefficiently; and it must be a subject of regret to the scientific world, and more particularly all interested in remarkable specimens of the vegetable kingdom, that measures better calculated to secure as long as possible the preservation of a tree so extraordinary by its age and dimensions, should not have been taken by the authorities of the island. According to the latest accounts its circumference was about 78 feet, and its total height about 3 feet less.

— The following circular, which has been promulgated at Aldershot, will prove of incalculable advantage to the troops in the division, as there is a large quantity of ground that can be easily cultivated, in addition to that already in the hands of the soldiers:—"SOLDIERS' GARDENS.—The Secretary of State has decided to allow the issue, at the public expense, of tools for the cultivation of garden ground allotted to the troops under War Office Circular dated 2d March, 1865. The tools will not be issued to individual soldiers permitted to cultivate gardens; but each company cultivating a garden will, on application to the barrackmaster, through the General or other officer commanding, be supplied with one set, consisting of one of each of the following articles:—Spade, digging fork, large and small rake, large and small hoe, trowel, dibble, line and reel, pickaxe, mattock, grubbing hoe, large and small waterpot, wheelbarrow. Barrackmasters will have in store one set of tools for each company the barracks where garden ground exists will contain.—EDWARD LUGARD."

— AMONG nurserymen the last of the old race of Scotch Dicksons has passed away in the person of Mr. JAMES H. DICKSON, of Chester, who expired on the 28th ult. at his house, Newton Villa, Chester, in the 72nd year of his age. Mr. Dickson and his cousin, the late Mr. Francis Dickson, established the Chester nurseries in the early part of this century, and through their enterprise their nurseries became among the most extensive in the kingdom. A few years ago the partners separated, and formed independent establishments, which are now conducted by their respective families.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Asparagus, to keep up a succession fresh beds will require to be started every three weeks. A temperature at the roots of 65° is sufficient. When fresh beds are made, and there is danger of overheating, it is advisable to have some rows of drain pipes across the bed, by opening the ends of which the superabundant heat will escape. They will also be useful in diffusing the heat of a lining when necessary. *Cress*, sow this and *Mustard* once a week in a little heat; the soil can scarcely be too dry. For all these purposes much fermenting material

is necessary, but there is always a quantity of refuse from the flower garden as well as the kitchen garden, which, instead of being taken to the rubbish heap, would be made available in the frame ground. *Carrots*, a slight hotbed should be prepared for Horn Carrots and *Radishes*, to succeed the crops now coming into use. *Rhubarb* and *Sea-kale* will be most economically obtained at this period by taking them up and planting them thickly in a slight hotbed. Fresh plants will be required every season.

FRUIT GARDEN.

Gooseberries and Currants, if pruned, may now be washed over with a mixture of cow dung, clay, soot, and lime, brought with water to the consistency of thick paint. Plums and Cherries will be benefited by washing with a similar mixture, adding to it, if thought necessary, tobacco water and flowers of sulphur. Where the planting of fruit trees is not yet finished, it should be deferred a month or six weeks longer; meantime prepare the ground for their reception. It often occurs that in attempting to obtain a very early crop of Strawberries, the plants are subjected to too much heat and kept too close, and failure is the consequence. They should be kept cool at first, and have plenty of air daily, except during frost or cutting winds. They should on no account be subjected, as is often done, to the same treatment with regard to heat and air, as Vines and Peaches, till after the fruit is set, when they will do well on the viney or Peach-house shelves.

FLOWER GARDEN.

Where any of the beds require the soil to be renewed, frosty mornings offer the opportunity of doing the work cleanly and expeditiously. By far too little attention is paid to trenching and draining flower beds; it is surprising how much better tender plants support the summer drought in beds that have been trenched than in those which have been merely dug. Any of the annuals that have been injured by the late frosts had better be cleared away; and if the ground between the plants can be stirred-up on a dry day with a small hoe, it will do them good. Wallflowers, Sweet Williams, Hollyhocks, and any of the more hardy biennials, may be removed to the flower borders. Wallflowers, if for their fragrance only, should be planted abundantly in all gardens. Mice will often attack *Polyanthuses* at this time of the year, especially when in frames, and commit serious ravages by eating out the hearts, and it will require some vigilance on the part of the grower to prevent this. Snails and slugs are great pests both to *Auriculas* and *Polyanthuses*. A little fresh bran placed under a flat tile, raised at each corner by small pebbles, is found to be the best trap amongst the many recommended.

GREENHOUSE AND CONSERVATORY.

The grand point to attend to in the greenhouse is to keep the plants from growing till as late in the spring as possible; such plants as show a disposition to grow early should be removed to the coldest part of the house or to cold frames in mild weather—anything rather than an early spring growth, unless for some special purpose. As fires are seldom wanted for drying-up the house after this time, as little fire heat as possible should be used, and any covering at hand to throw over the glass in frosty weather will lessen the necessity for strong fires. Besides saving coals, this will be much better for the health of the plants. *Pelargoniums* and *Cinerarias* require more heat than the woody greenhouse plants, and are kept in houses by themselves in nurseries and large establishments; but where there is only one house for the whole, they may be kept in the warmest end. Orange trees that have been forced last spring, and kept in-doors all summer, will now begin to grow; and if they are in good condition they will flower freely on the young wood and little side spurs. In order to bring them into regular shapes, the strongest shoots ought to be stopped occasionally with the finger and thumb, not, however, until after the flowering is over. March is time enough to repot established plants of these; but young ones in small pots may be shifted now and turned into bottom heat in the forcing pit. No plant delights in bottom heat more than the Orange, and few plants which will live over the winter in a low temperature like it will stand more stove heat at all times when treated as a stove plant. Another peculiarity noticed in the Orange is, that it requires less earth to grow in to produce heavy crops of fruit than any other plant of the same size. Bad drainage and too large a pot will soon injure it. Avoid as much as possible letting into the conservatory strong currents of cold air at any time, even when going in or out by the door; but in mild weather you may give air for

several hours in the middle of the day. Water early in the day, and keep the plants constantly clean from dust and insects.

STOVE.

A few plants will now or soon begin to grow in large collections. Some time ago this used to be the first note of preparation for potting, but now few gardeners will pot or shift plants for the next six weeks. A good criterion for the time of spring-potting any plant is when the roots are observed to grow freely. It follows, therefore, that plants which are grown in bottom heat will require shifting much sooner than those on shelves. Pruning is more or less necessary for almost all plants, and the time for this work is regulated by that when the plant is expected to flower. The management will entirely depend upon the time the plant is wanted to flower; but he who flowers his plants nearest their natural time will, of course, have the most success. Little water should be given this month, and the house should be kept at a comparatively low temperature. Now that some of the Orchids are beginning to grow, great attention must be paid to the young and tender shoots, to see that no moisture lodges in their centres or inside the stems or bulbs.

FORCING PIT.

Roses of all sorts do better when first brought into a temperature of 55°, with a bottom heat of 75°, and not to pass 60° till all the eyes are fairly started. A dry atmosphere is best for very early forcing; we can always supply moisture as we think necessary. Recently built pits, and especially where tanks are used, are troublesome for this branch of gardening, owing to the amount of moisture they have in their atmosphere.

PITS AND FRAMES.

When the weather will not permit the lights to be taken off, you can improve and sweeten them very much by tinning them during the day—that is, let two men take hold of the light, one at top and one at bottom, and then turn it over. The inside will thus be exposed to the air, and the inner surface of the glass will be dried. All sorts of pits, whether for hardy plants or for forcing, should occasionally have the lights turned during the season, particularly in winter and spring.—W. KEANE.

DOINGS OF THE LAST WEEK.

Much of the work up to and including the 11th instant was done in-doors, except when such work as wheeling, turning heaps of soil, and chopping wood for furnaces was carried on. Many cuttings of hedging plants were put in, and placed where they would have a little bottom heat. Plants were shifted, houses cleaned, and orchard-house trees pruned, washed, and regulated. We might have trenched and ridged but for our reluctance to bury snow in the ground, which with us is generally cold enough without doing so, and as the house work wanted attention we put off what might have been done out of doors until more seasonable weather, making preparations to sow many seeds under glass in the beginning of the next week.

The 11th was a very singular day with us. When the thermometer against a wall, at 5 feet from the ground, indicated 5° below the freezing point, rain was falling heavily; and though during the day the temperature rose to nearly 32°, the rain froze almost as fast as it fell, rendering walks that had been previously swept like so many sheets of glass, and therefore dangerous to traverse. Copings of walls, and even walls themselves, exposed to the south, as the wind was due south, became a sheet of ice. Doors in garden walls that go very easily were so frozen in their places as to become immovable; and one or two which we could not well allow to remain shut, we had to relieve by heating all round the sides with a mallet, so as to break the ice. The covering of the wall and wood of the trees with ice will do the latter no harm; but when the bricks are soft we have seen large holes show themselves after a thaw. As to insects, none living could well escape, and even myriads of eggs would be destroyed. We once noticed some Pear trees that were much covered with the small scale insect; but such an ice covering as the above for a couple of days left the bark almost free of them. The next spring they and the injured bark fell off, or could easily be brushed off with a hair broom. Since then we have sometimes syringed such trees all over when we have anticipated a sharp frosty night, and we have noticed that this was most effectual when warm water was used to wet the trees and the wall.

Gutters and Spouts of Houses.—These wanted looking after, even in gardens, and more especially in mansions, where the rain from the roofs passed to lead gutters surrounded by a

parapet. The danger in such a day as Saturday arose from the orifices of the carrying-off pipes being frozen up. We had all ours cleared out on account of the snow; but the pipes were so frozen on the 11th, that if they had not been opened with large weeding irons the water would have accumulated in the gutters, and then have found its way through the roofs and the ceilings below. Even in the garden we found at the top of the discharge pipes the little tanks that received the water from the spouting filled with masses of solid ice, though quite free and open in the morning. It is of comparatively little use crying out after the mischief is done; but forgetfulness of the tops of discharge pipes becoming firmly iced-over in such a day as the 11th might cause much discolouring and falling of ceilings in upper rooms. In the case of common spouts round buildings, we expect to hear of much injury to them from the weight of ice in them, and hanging in huge icicles from them. Whilst in such a state they could not serve their purpose of taking the water away from the walls.

This reminds us that the whole subject of spouting requires consideration, and those who have had much experience with it would confer a favour by stating the best material to use. On the whole we are inclined to favour zinc or galvanised iron, only the galvanising renders it brittle. Tin is the most easily managed, and when kept painted will last a considerable time; but if the painting is neglected it soon rusts out. Cast-iron piping in lengths of 6 or 9 feet, well painted, is very lasting where it is not likely to be interfered with; but in places where workmen come in contact with it, it is found to be very brittle in severe frost. Even when placed in a lofty position, such pipes are apt to chip and crack when filled with ice, which they are very likely to be, as spouting round buildings does not generally have a greater fall than is necessary to take away the rain water. This is all very well in weather that is not frosty; but in such weather as that which occurred on the 11th, and even in circumstances less favourable for producing the same results, the pipes soon become filled with ice, even with the outlets from them all open. Iron pipes are more apt to crack and break from frost if painting is neglected. In large establishments, keeping the spouting in good order forms such an item of expenditure, that any suggestions on the subject would be interesting. One objection to cast iron is the weight, involving the necessity for stronger brackets for fixing; and when used for garden houses or pits it is well to have the best hard wood, in the shape of bricks, fixed in the wall for fastening the brackets to by means of screws.

General work has been much the same as last week. All things protected under hand-lights, and in cold pits and frames, as Calceolarias, Cauliflowers, Lettuces, Endive, and Radishes, have given little trouble, as they have not been uncovered for eight days, and even what was uncovered, as Asparagus in a hothed frame, was little the better for it, as the weather was too dull to green the shoots properly. The wind on the 11th turning to the south-west, we may expect ere long the disappearance of the snow, and brighter and sunnier weather, when everything will be again exposed to the light. The snow has been a great protection for all out-door vegetables, and even Turnips and Wheat in the fields. Our best farmers have long since secured their Turnip crops in heaps, protected from frost and vermin.

Our window-gardening friends have had rather a troublesome time, but there has been nothing to prevent success, if the plants are kept clean, kept close to the window during the day after the room was warmed by the fire, and placed in the middle of the room in the coldest nights. Bulbs will now be very attractive, and it will be well to have some in glasses that the young scions of the family may be interested in seeing the rooting process. The fostering of such tastes in those beyond babyhood often proves a source of enjoyment for a lifetime.—R. F.

TRADE CATALOGUES RECEIVED.

B. S. Williams, Victoria and Paradise Nurseries, Upper Holloway, London, N.—*Descriptive Catalogue of Flower and Vegetable Seeds.*

Lucombe, Pince & Co., Exeter.—*Select List of New and Rare Plants, Conifers, Trees, and Shrubs, &c.*

COVENT GARDEN MARKET.—JANUARY 15.

THERE are no alterations worth notice. A slight improvement may be observed in the demand for a few choice articles, but that is partial and limited to country orders. Very large arrivals of Oranges are reported, and prices must recede.

TO CORRESPONDENTS.

GRAFTING WAX (Southampton).—Take common sealing wax, any colour but green, one part; mutton fat, one part; white wax, one part; and honey, one-eighth part. The white wax and the fat are to be first melted, and then the sealing wax is to be added gradually, in small pieces, the mixture being kept constantly stirred; and, lastly, the honey must be put in just before taking it off the fire. It should be poured hot into paper or tin moulds, to preserve for use as wanted.

HAYS'S PATENT STOVE (T. C.).—You are only one of many who cannot obtain peat charcoal. Surely there must be some to be had of the company who manufacture it for manure. Can any of our readers give relative information?

GAS LIME FOR MANURE (C. B. F.).—It is a compound of sulphate of lime—which becomes gypsum (sulphate of lime) by exposure to the air; and a little ammonia is mixed with it. It has been found very beneficial to all the Clovers, Turnips, and other members of the Cabbage family. Thirty bushels per acre are sufficient. The idea that this manure encourages the growth of coarse Grasses is quite erroneous.

CONFREY (J. W. Edgar).—It is a native of England, and commonly found on the banks of wet ditches and rivulets. It is called by botanists *Symphytum officinale*. The roots contain much mucilage, and are employed in making drinks for those afflicted with coughs and other internal irritations. The leaves are aromatic, and used to give a flavour to cakes, &c. The young stems and leaves are boiled for use as a culinary vegetable.

LILIAM MONADELPHUM SUPERBUM.—We are informed that this can be had of M. Max Leichlin, Karlsruhe, Baden.

ORCHID BASKETS.—A correspondent, "H. H.," wishes to know where these figured in Appleby's, "Orchid Manual" can be purchased.

VINE IN A FERN CASE (Valentine Dalton).—A Black Hamburgh or a Royal Muscadine will be the best Vine, if your case is to stand in a room and have no heat except what the room affords. For your box 2½ feet long, 1 foot wide, and 18 inches deep for the Vine, we advise you to have the bulk of the soil fibrous loam, and mixed with a peck of lime rubbish, half a peck of broken boiled bones, and as much charcoal in small pieces, not dust. In this the Vine will grow well, and you can keep up the strength by rich top-dressings.

GLADIOLUS ON NORTH ASPECT (Fred).—The Gladioli will not succeed on the north side of a house, where it will have but little sun. It should have a good situation, and no shade whatever. To make a showy bed the bulbs should be planted from 9 inches to 1 foot apart; and in planting, silver sand will answer best to place around the bulbs; but clean river sand will do.

LORELAS AND TROPICOLMUS FROM SEED (Idem).—Plants from seed grow much more freely than those from cuttings, and they flower very well the first year, but not so early as plants struck from cuttings.

PAINTING A GREENHOUSE (Idem).—You ought to have given the greenhouse at least one coat of paint before it was put up; and as soon as the putty, after glazing, had become hardened, two or three coats of lead and oil paint ought to have been given. We advise you to lose no time in having it well painted, taking care to have the woodwork thoroughly dry before applying the paint, otherwise painting is worse than useless.

CAMELLIA BLOOM BUDS FALLING (E. N.).—The cause of the buds falling is an insufficient amount of food supplied to them by the roots, in consequence of these being inactive or not numerous enough to maintain the plant in a healthy state. You can only effect a remedy by promoting a more healthy root action. Probably the plant requires a change of soil, the drainage may not be good, or too many buds may have been left. One or at most two buds are sufficient to leave upon each shoot.

CAMELLIA LEAVES STICKY (A Subscriber).—We think that the Camellias are infested with scale; and in that case your remedy will be the washing of the plants with a sponge dipped in a solution of soft soap at the rate of 4 ozs. to the gallon of water, giving the plants a thorough cleaning on the under as well as the upper surface of the leaves, and the shoots and branches should be well washed. This will also free the plants of the mouldy spots, and be very beneficial. The Primula leaves are probably sticky from the plants being placed under the Camellias, and their leaves being covered with the secretion of the scale insect on the Camellias. If you perceive very small pale brown spots on the midribs of the leaves, or at the angles formed by the junction of the leaves or buds with the shoots, pick them off with the point of a knife. These are the scale insects that make the leaves sticky and cause the mouldy spots. Fumigation with tobacco will not be effectual. You should keep the plants well supplied with water, but not give any until the soil becomes dry; then afford a good supply. A temperature of from 40° to 45° by night, and of 50° by day, is sufficient at this season, and in that your Camellias ought to swell their buds well.

AQUATIC PLANTS FOR PONDS (J. F. Boyd).—Nothing is more simple or easy than the culture of aquatic plants, providing the bottom is covered with a few inches thick of mud, and the plants are well planted. Before the plants are put into the water they should be fastened to a piece of charred turf containing enough soil to sink it. Small or large stones in proportion to the size of the plants will answer the same purpose. Thin copper wire is best for securing the plants to the turf or stones. The plants may then be dropped into the water at the places required. In the deepest parts you may plant *Najas lutea*, *Nymphaea alba*, *Alisma plantago*, *A. lanceolata*, *Iris pseud-acorus*, *Ranunculus hydrophyllum*, *Typha latifolia*, and *Vallisneria spiralis*; whilst near to the margin you may plant, but in water of a depth of 1 foot or a little more, *Stratiotes aloides*, *Vallisneria spiralis*, *Pontederaca cordata*, *P. lanceolata*, *Myriophyllum spicatum*, *Hydrophyllum purpureum*, *Hottonia palustris*, *Butomus umbellatus*, *Utricularia vulgaris*, *Ranunculus aquatilis*, *Hydrocharis mors-ranunculi*, *Carex acutifolia*, *Potamogeton densum*, *P. gramineus*, *Sagittaria sagittifolia* and its double variety, *Cyperus glomeratus*; and on the margin, in the water but not overhead, *Cardamine pratensis*, *C. pratensis flore pleno*, *Caltha palustris*, *C. palustris flore pleno*, *Ranunculus tripartitus*, *Justicia pedunculata*, *Menyanthes trifoliata*, and *Lysimachia thyrsiflora*.

LIMEWASHING GOOSEBERRY BUSHES (Ignoramus).—Limewash applied to Gooseberry bushes will not injure them in the least; on the contrary, it will free the stems of moss, and to a certain extent prevent the depredations of birds. Nothing is so effectual in keeping birds from the buds as stringing the bushes with worsted, extending this from branch to branch, and crossing it as much as possible, so as to form meshes about 2 inches wide.

AMERICAN BLIGHT (Idem).—The presence of American blight is indicated by the branches having a white snow-like down hanging on them, and the shoots swelling where it appears. The remedy is to apply train oil with a brush to the parts affected.

SCALE ON PEAR TREES (Idem).—This may be detected by the oblong speck-like appearance of the insect on the shoots, and especially on the spurs. The insects may be removed very readily with the point of a knife, and a dressing of train oil will destroy them. It should be applied whilst the trees are at rest.

ORCHARD TREES UNFRUITFUL (New Subscriber).—We think your only remedy is to have the ground drained. An occasional flooding would do no great harm; but as your soil is a stiff loam, too much water probably lodges in the subsoil, and owing to its not passing away, the growth does not ripen well. We know a similar case, where drainage effected a complete cure. It is difficult to explain why some trees should be fruitful and others unfruitful. Unfruitfulness is sometimes constitutional, sometimes an effect of soil and climate. Carter's Prolific Raspberry will no doubt bear, only do not shorten the canes much, as from their vigour the side shoots may prove unfruitful. We should be glad if you would give us the names of the kinds of Apples that bear well in your soil. Such information is very valuable.

WIRE NETTING FOR PROTECTING FRUIT TREES FROM BIRDS (J. N. P.).—The mesh of the wire netting to exclude small birds should not exceed 1 inch. We presume you intend it to be moveable, and only to be employed to protect the buds in spring and the fruit in summer, in which case it would be excellent; but if kept over the trees permanently we fear it would exclude light to an injurious extent.

BIGNONIA JASMINOIDES NOT FLOWERING (L. E.).—The piece of shoot enclosed was that of the *Jasminum* Bignonia, a very handsome climber for a greenhouse. The plant is probably too liberally potted, and is growing very freely. We would confine its roots, still allowing them enough of pot room for the plant to make a good growth. It should be kept well supplied with water whilst it is growing, but when at rest little water will be necessary. The shoots must be kept moderately thin, so as to expose them fully to light and air, and the lighter and nearer they are to the glass the better will be the chance of bloom. The fern fronds sent are those of *Adiantum assimile*, or a weak form of *Adiantum cucullatum*, but we are unable positively to ascertain which without seeing better specimens.

STOVE PLANT CULTURE (A Seven-years Subscriber).—The *Allamandias* may be pruned in February, cutting out the old and bare straggling shoots, and shortening the growths of the previous year, leaving enough young shoots or wood to furnish new shoots. When the plants have begun to grow they should be carefully turned out of the pots and re-potted, removing as much of the old soil from amongst the roots as possible, using for that purpose a pointed piece of wood, and taking care not to injure or disturb the roots more than can be avoided. The plants, if large, may be placed in the same size of pot as before; but if large specimens are wanted and the plants are young and vigorous, it would be well to give them larger pots. Good drainage and clean pots should be afforded, and a compost of equal parts of sandy fibrous peat, turfy loam, and leafmould, well mixed with about a fourth part of pieces of charcoal from the size of a pea up to that of a hazel nut, and silver sand. The peat and loam should be torn in pieces with the hand, and be used rather rough, pressing the soil rather firmly about the roots in potting. The compost should be dry rather than wet. A gentle watering may be given after potting, and the plants should be sprinkled overhead twice daily with water of the same temperature as the house, and every available

surface in the house should also be kept moist, so as to maintain a moist atmosphere. The temperature should be from 60° to 65° at night, and from 75° to 80° by day with sun. Care should be taken not to overwater the plants, but to keep the soil moist until the plants are growing freely, when liberal supplies of water will be needed. *Clerodendron Thomsonei* will succeed with the same treatment as described for the *Allamanda*. *Bougainvillea speciosa* and *speciosa* may have all the old bare shoots cut off, preserving the best well-ripened shoots, of which only the points should be taken off. The plant may be potted in a compost of sandy fibrous loam two-thirds, and one-third leaf mould, with a free admixture of sharp sand. Every encouragement should be given to ensure a good growth, which, being made, the plants should have the lightest and most airy situation that can be given, and the supply of water must be gradually reduced to just sufficient to keep the foliage fresh. The *Stephanotis* will thrive if treated in the same manner as the *Allamandas*; only in pruning, the shoots should not be shortened, merely removing the long bare shoots, and thinning the others out if very close together on the trellis. Leave the strongest, best-situated shoots with prominent eyes.

CLIMBERS AND PLANTS FOR CONSERVATORY (Bellis).—We cannot recommend annual climbers for a conservatory. They are of too short duration, and leave gaps when they are over. Permanent plants are far better. We would advise you to procure *Kennedy* *inophylla floribunda*, *Jasminum gracile variegatum*, *Lapageria rosea*, *Mandevilla sanderiana*, *Passiflora Newmanni*, *Rhynchospermum jasmynoides*, and *Sollya linearis*. If you require any for the back wall, *Luculia gratissima* and *Labrothamnus elegans* would probably succeed, only the climbers on the roof must not be nearer them than 3 feet. A few good plants for a conservatory are *Acacia armata*, *oleifolia elegans*, *longifolia macrocarpa*, and *grandis*; *Chorozema cordata splendens*, *Citrus japonica* (Otaheite Orange), and *C. nobilis* (Mandarin Orange), *Coronilla glauca variegata*; *Daphne indica*, *Erythrina candida-galli*, *Hibbertia Reidi*, *Indigofera decora*, *Elaeagnus coccinea superba*, *K. miniata grandiflora*, *Lilium auratum*, *L. laucifolium*, *Lilium trigynum*, *Monochaetum ensiferum*, *Myrtus communis*, *Polygala Dalmanisiana*, *Rhododendron jasmyniflorum*, *Statice brassicifolia*, *S. profusa*, *Wisteria corymbosa*, and *Vallota purpurea*. You will, of course, have *Camellias*, *Azaleas*, *Primulas*, *Cinerarias*, *Cyclamens*, *Calceolarias*, *Pelargoniums*, and *Fuchsias*; and if you have a cold pit you may wish safety indulge in a few of the hard-wooded plants; but unless you have a pit to move them into in summer your success will be very indifferent with them. We name a few:—*Acrophyllum venosum*, *Aphellex macrantha purpurea*, *A. prolifera* *Barnesi*, *Boronia Drummondii*, *B. serrulata*, *Chironia glutinosa*, *Correa speciosa major*, *Brilliant*, and *delicata*; *Crocea saligna major*, *Dracophyllum gracile*, *Dillwynia Henchmanni*, *Eriostemon intermedium*, *Genetilla tulipifera*, *Grevillea panicea splendens*, *Leschenaultia formosa*, *Fimelia decussata*, *P. Hendersoni*, and the following *Epacris*—viz., *hyacinthiflora*, *Lady Penmore*, *The Bride*, *delicata*, *grandiflora rubra*, *rubella*, and *miniata splendens*. They are very desirable for early spring and early summer bloom. After blooming they should be removed to a cold pit. A few plants having ornamental or variegated foliage will add much to the effect—*Arundo donax variegata*, *Chamaerops Forluni*, *Dracena australis*, *Fartichum grande*, *Hydrangea japonica variegata*, *Isoplexis gracilis*, *Phormium tenax*, *Sansevieria carnea variegata*, and *Sedum Scholdii variegatum*. We have, probably, named many more than you will require; but you may select from them what you will have accommodation for. Do not obtain too many, but allow every plant plenty of room, as a few plants well grown will be more satisfactory than many crowded together and spoiling each other. *Balsams*, *Coleus argentea*, *C. pyramidalis aurea*, *C. pyramidalis coccinea*, *Cockscombs*, *Globe Amaranths*, *Sensitive plant*, *Thunbergia alata*, and its white variety, are fine tender annuals for conservatory decoration, requiring to be raised and grown in both beds. *Achimenes* would succeed, also *Gloxinias*, if you were to forward them in the beds and grow them there until showing for bloom. *Chionanthus Danpurii* and *Taeniola Van Volckm* would most likely succeed in your house.

STRAWBERRY FORCING (Idem).—Presuming the plants to be in pots well filled with roots, you may remove them to a shelf near the glass, where they can have abundance of air. The plants should be carefully watered until they are coming into flower; afterwards they should be well supplied with water, and when the blooms are setting the pots may be put in saucers kept full of water. You cannot give too much air and light. Strawberries will do well in any house having a greenhouse temperature. We should prefer a well-grown plant of *Pteris tricolor* to *Blechnum cornu-adeense*, as the former can be kept in one-fourth the space, and is much richer in colour; but a well-grown plant of the *Blechnum* is very ornamental from its graceful tree-fern-like habit, and the rich pink of its young fronds.

GRAFTING ROSES (J. P.).—Manetti stocks grafted with *Roses* in February or early in March, according to the season (it being necessary to graft when the sap in the stocks is rising, and before the seasons have begun to grow), are in general successful; but not so much so as when the stocks are placed in a frame over a gentle hotbed and kept close. Grafting being performed by the whip process, the junction should be clayed; and the best protection that can be afforded is to cover the union firmly with soil, raising it around the stock in the form of a cone, with one or two of the eyes of the graft only left above the surface. If the grafts succeed they will show bloom buds, and on the vigour of the plants at the usual season, dependant, of course, on the vigour of the plants and the maturity of the wood used for grafting. Bottom heat insures a more speedy and certain union of stock and graft. Stocks may be planted in soil over a hotbed and covered with a frame kept close, and being grafted they will succeed; but the success is not so certain, nor the growth so good, as when the stocks are established in pots. The grafted plants may be removed in May, after they have been well hardened-off, and if carefully removed and watered the check will be slight. The union of stock and graft will be complete in three or four weeks; but the time is dependant on the temperature. In the open ground it will be about six weeks. The best indication of the union being effected is the putting-forth of fresh shoots, and when these are 3 inches in length the union may be considered complete. There is not, that we are aware, any objection to the grafting of Briar stocks in February or March. It was practised before the Manetti was known as a stock; but the latter is now in greater repute, and we think, deservedly so. The number of eyes left on the graft, or their being long or short, may not have any great effect on the success of the operation, but it has on the plants' after-growth, for the shorter they are the more vigorous will be the growth of the shoots made by the graft. Cuttings of the Manetti Rose will grow if put in in spring, but not so well as if planted in autumn.

ROSES IN DECEMBER AND JANUARY (M. R.).—If *Roses* are required for the time they must not be allowed to bloom more than one previous series. Their flower buds should all be cut off by the 1st of August. The plants should then be potted in 6, 8, or 12-sized pots, and placed aside. Before frosts set in they should be taken into the vinery, a gentle heat being afforded in very cold weather, and air should at all times be given them. I do not practise this myself, as I have *Roses* sufficient for my purpose out of doors. I cut my best bouquet January 4th. In mild winters I have them till February. The best *Roses* for glass houses are the *Teas*, *Tea-scented Noisettes*, and *Hybrid Perpetuals*. After a little time they will supersede all others in or out of doors. Moss and variegated *Roses* at present must be looked for among the summer *Roses*. The following is a list of the best of *Roses* for the purpose required:—*Tea-Rose*: *Adam*, *Bouquet*, *Safrano* (these two are only good in a bud state); *Gonbault*, *peculiar scent*; *Elise Sauvage*, *Devoniensis*, *Madame Margottin*, *Vicomtesse de Cazes*, *Madame Willebrord*, *Souvenir d'un Ami*, *Souvenir d'Elise*, *Kobus*, and *Sombreuil*. The last is the hardiest of the race. *Tea-scented Noisettes*: *Marcel Niel*, *Solfaterra*, *Gloire de Dijon*, *Lamarque*, *Celine Forestier*, *Isabella Gray*, and *Triomphe de Rennes*. *Hybrid Perpetuals*:—*Rose-coloured*: *Comte de Nanteuil*, *William Griffiths*, *Bernard Prevost*, *Comtesse Cecile de Chabillant*, *Louise Margottin*, *Baron Gouelle*, and *Duchesse de Morny*. *Black*: *Marguerite de St. Amand*, *Caroline de Sansal*, *Souvenir de la Malmaison*, *Duchesse d'Orleans*, and *Saint des Anges*. *White*: *Madame Vidol*, *Madame Rivers*, *Miss Ingram*, *Madame Freeman*, and *Madame Alfred de Rougemont*. *Crimson*: *Charles Leclerc*, *Senateur Vaisse*, *Madame Victor Verdier*, *Victor Verdier*, *Jules Margottin*, *Madame Rontin*, *Marcel Vaillant*, *Madame Julie Baran*, *Duchesse de Caylus*, *Lady Suffield*, *Baron Adolphe de Rothschild*, and *Alfred Colomb*. *Dark Crimson or Maroon*: *Pierre Notting*, *Prince Camille de Rohan*, *Empereur de Maroc*, *Duc de Cazes*, and *Souvenir de Dr. Jaccard*, a beautiful *Rose*.—W. F. RADCLIFFE.

CHARCOAL ASHES (A Young Gardener).—They would not do as a substitute for peat; but they would be an excellent manure for any crop. Spread them over any plot just before digging, at the rate of about forty bushels per acre.

BURNING MOSS GREEN (J. E.).—Cover it over half an inch deep with dry sand, and dry thoroughly by exposure in an oven heated sufficiently just not to burn it.

NAMES OF FRUITS (Trilob).—*Aphel*—1, Trumpeter; 2, Louis's Pearmain; 3, Blenheim Pippin; 4, Winter Greening; 5, Hollandbury; 7, Costard or Catshead; *Pear*: 1, Verulam.

NAMES OF PLANTS (Prill-well).—It is only a fasciated stem of *Daphne laureola*, commonly called *spurge Laurel*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending January 14th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
			Air.		Earth.				
	Max.	Min.	Max.	Min.	1 ft. dp.	2 ft. dp.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

GREEN GEESE.

I SEE you had an article on Geese in the Journal. Relative to the Green Geese, it is defective; and if Mr. Dixon should

ever be in Norwich at the fair held in the beginning of April, he will see goslings, fit for eating, in the market, mostly at 10s. each, the produce of Geese which lay three times a year. I know of none anywhere else. They are called Green Geese because they are fit to kill just when the country is becoming green.—H. W.

[You are correct in all but the derivation of the name. They

are called Green Geese because they were formerly killed while covered with their green down. Fifty years ago they were killed and scalded. The *gourmets* of that time used to say such Geese were too old if they had a bone; others condemned them unless they were young, and consequently soft and pulpy enough to allow the meat to be sucked through a quill. Green Geese are to be had in Leadenhall in February. The supply only ceases when full-grown, naturally-reared birds supersede them.]

DUCKS FROM THE ISLAND OF PERU.

A CORRESPONDENT signing himself "T. C. H.," on page 20, desires information about the island of Peru. Having, I imagine, been at school more recently than he has, I am, perhaps, better up in my geography. The island of Peru, from which the magnificent white Musk Ducks come, is in a different part of the world from Peru. If "T. C. H." will refer to a map of the islands in the North Pacific Ocean, he will find that close upon the equator is a group of islands, called the Gilbert Islands; and amongst these, in south latitude $1^{\circ} 10'$, and east longitude $176^{\circ} 5'$ (if the map is on a sufficiently large scale), he will find the island of Peru. This island, let me suggest to those whose curiosity has been excited, is noted for the beauty of the Ducks which inhabit it, and is that which is incidentally alluded to in the advertisement.—W. H. K.

HANLEY POULTRY SHOW.

THE third annual Exhibition of Poultry, Pigeons, Cage Birds, and Rabbits was held in the Covered Markets and Town Hall, Hanley, on the 7th, 8th, and 9th of January. The following is the list of awards:—

DORKINGS (Coloured).—First and Extra Prize for best pen of Dorkings, Mrs. F. S. Arkwright, Etwell Hall, Derby. Second, J. D. Hewson, Stafford.

DORKINGS (Any other variety).—First, Withheld. Second, Rev. E. S. Tideman, Brentwood.

SPANISH.—First and Extra Prize for best pen of Spanish, Polish, or French, F. James, Peckham Rye. Second, H. Beldon, Bingley. Highly Commended, E. Comber, Warrington; J. Walker, Wolverhampton; J. Mansell, Longton; J. Wright, Melton Mowbray.

COCHIN-CHINA (Cinnamon and Buff).—First, Col. Stuart Wortley, Grove End Road, London. Second, H. Tomlins, Mosley. Highly Commended, C. W. Brierley.

COCHIN-CHINA (Any other variety).—First and Extra Prize for best pen of Cochins or Dark Brahmans, E. Tudman, Whitechurch. Second, J. R. Reddard, Bristol. Highly Commended, H. Hobson, Walsall.

BRABMA POOTRA (Dark).—First and Extra Prize for best pen of Brahmans, H. Lacy, Holben Bridge. Second, H. Lingwood, Bucklesham. Highly Commended, J. Heath, Nantwich.

BRABMA POOTRA (Light).—First, H. Lacy, Holben Bridge. Second, A. O. Worthington, Burton-on-Trent.

HAMPELTONS (Black).—First, J. Walker, Denton. Second, W. Green, Keighley. Highly Commended, W. Holt, Middleton; Rev. W. Sergeantson, Shrewsbury.

HAMPELTONS (Golden-pencilled).—First, F. D. Mort, Stafford. Second, G. Swift, Fulford. Highly Commended, W. Kirby, son, Trentham.

HAMPELTONS (Silver-pencilled).—First and Extra Prize for best pen of Hamburgs, Duke of Sutherland. Second, H. Beldon, Bingley. Highly Commended, Messrs. W. A. S. Bairstow, Bingley; J. Platt, Bolton.

HAMPELTONS (Gold-banded).—First, H. Boushaw, Uttoxeter. Second, T. Burgess, Whitechurch. Highly Commended, W. A. Hyde, Ashton-under-Lyne; J. Davis, Birmingham.

HAMPELTONS (Silver-spangled).—First and Second Extra Prize for Second best pen of Hamburgs, Duke of Sutherland. Second, H. Beldon. Highly Commended, Mrs. Flynn, Kidsgrove; Duke of Sutherland.

POLISH (Any variety).—First, J. Heath. Second, P. Unsworth, Newton-le-Willows. Highly Commended, R. Charlesworth, Manchester; J. Percival. Commended, H. Beldon.

FRENCH (Any variety).—First, Col. Stuart Wortley. Second, H. Beldon. Commended, R. Brown, Cheadle Hulme; O. Drowry, M.D. Walsall.

GAME (Black-breasted Red).—First, G. Swift. Second, A. O. Worthington. Highly Commended, G. Bagnall, Draycott; T. Burgess; Rev. W. J. Mellor, Colwick Rectory, Notts.

GAME (Brown and other Reds).—First and Extra Prize for best pen of Game, C. Barnett, Nantwich. Second, Messrs. Church & Houlding, Nantwich. Highly Commended, G. Swift.

GAME (Any other variety).—First, H. M. Julian, Hall. Second, G. Lunt, Market Drayton.

GAME.—*Cock*.—First, T. Whittingham, Nantwich. Second, C. W. Brierley. *Cockerel*.—First and Extra Prize for best Single Cock or Cockerel, G. Swift. Second and Highly Commended, T. Burgess.

DORKINGS (Any variety).—*Cock*.—First, Hon. Miss Douglas Pennant, Penhryn Castle. Second, F. S. Arkwright.

COCHIN-CHINA (Any variety).—*Cock*.—First and Extra Prize for best, Cochins or Brahma Cocks, E. Tudman. Second, F. E. Richardson, Uttoxeter. Commended, O. Dewry, M.D.; A. O. Worthington.

BRABMA POOTRA (Any variety).—*Cock*.—First, L. Poulton, Biddulph. Second, Hon. Miss Douglas Pennant. Commended, H. Dowsett, Melsby, Chelmsford; F. James.

HAMPELTONS (Any variety).—*Cock*.—First and Extra Prize for best Brahma Pootra or Hamburg Cock, Duke of Sutherland. Second, H. Beldon.

GAME BANTAMS (Black-breasted Red).—First, J. H. Lasbrey, Uttoxeter. Second, W. Hodgson, Darlington. Highly Commended, Rev. E. S. Tideman. Commended, W. Baker, Colbridge.

GAME BANTAMS (Any other variety).—First and Extra Prize for best

pen of Game Bantams, H. Ashton, Prestwich. Second, W. Hodgson, Darlington.

BANTAMS (Gold or Silver-laced).—First, Withheld. Second, H. Draycott, Hamblestone.

BANTAMS (White, Clean-legged).—First, Messrs. S. & R. Ashton, Mottram. Second, H. Beldon.

BANTAMS (Black, Clean-legged).—First and Extra Prize for best pen of Gold or Silver-laced White or Black, Messrs. S. & R. Ashton. Second, Messrs. Tonkin & Tuckey, Bristol. Commended, Miss Bowden, Uttoxeter.

DUCKS (White Aylesbury).—First and Extra Prize for best pen of Ducks, Mrs. M. Scamons, Aylesbury. Second and Second Extra Prize for Second best pen of Ducks, E. Leech.

DUCKS (Rouen).—First, T. Dean, Keighley. Second and Highly Commended, T. Burgess.

DUCKS (Any other variety).—First, Rev. W. Sergeantson. Second, H. Savile, Ollerton.

GEES (White).—First and Extra Prize for best pen of Geese, J. Lycett, Stafford. Second, T. Burgess.

GEES (Grey or Mottled).—First, C. T. Dean, Astbury. Second, J. White, Wakefield. Commended, W. H. Stott, Rochdale.

TURKEYS.—First, E. Leech. Second, T. Burgess. Highly Commended, Mrs. Dale, Scarborough; F. E. Richardson. *Poults*.—First, E. Leech. Second, G. Swift. Highly Commended, F. E. Richardson.

TURKEY.—*Cock*.—First, E. Leech. Second, A. O. Worthington.

SELLING CLASS.—First and Second, N. Cook, Chesham. Third, G. Lamb, Compton.

Extra Prize to the Exhibitor gaining the greatest number of Prizes for Poultry, Duke of Sutherland.

PIGEONS.

TUMBLERS (Almond).—First, J. Fielding, Rochdale. Second, J. Hawley, Bingley. Highly Commended, Messrs. Newbitt; J. Beward, Coventry.

TUMBLERS (Any other variety).—First, J. Fielding. Second, J. Hawley. Highly Commended, J. Grace, Nantwich; T. Newell, Ashton. Commended, H. Yardley, Birmingham.

CARRIERS.—First and Extra Prize for best pen of Tumblers, Carriers, Pouters, Balbs, Beards, or Runts, J. Hawley. Second, — Gamon, Chester. Highly Commended, H. Yardley. Commended, — Skidmore, Nantwich.

POUTERS.—First and Second Extra Prize for Second best pen of Tumblers, Carriers, Pouters, Balbs, Beards, or Runts, A. Heath, Calne. Second, J. Hawley. Highly Commended, H. Yardley. Commended, A. Heath.

BALBS.—First and Second, J. Fielding.

BEARDS.—First, H. Yardley. Second, J. Fielding.

RUNTS.—First and Second, H. Yardley. Commended, H. Tomlinson, Birmingham.

JACOBS.—First, J. Hawley. Second, J. Edge, Birmingham. Commended, W. Massey, Kent; J. Thompson, Bingley.

FANTAILS.—First, Messrs. Hewitt, Lincolnshire. Second, J. Beward. Highly Commended, H. Yardley.

TRUMPETERS.—First and Second Extra Prize for best pen of Jacobsins, Fantails, Trumpeters, Owls, Nuns, or Turbits, J. Hawley. Second, W. Gamon. Highly Commended, Mrs. T. Robson, Penbridge; J. Thompson; J. Hawley; Rev. W. J. Mellor.

OWLS.—First and Extra First for best pen of Jacobsins, Fantails, Trumpeters, Owls, Nuns, or Turbits, J. Fielding. Second, J. Fielding. Highly Commended, T. Newell, Ashton. Commended, Messrs. Newbitt, Epworth.

NUNS.—First, J. Thompson. Second, J. Hawley.

TURBITS.—First and Second, T. Robson. Highly Commended, J. Fielding. Commended, R. Liddall, Shetfield.

BARDS.—First, Extra Prize, and Second for best pen in the Barb and subsequent classes, Rev. W. J. Mellor. Highly Commended, J. Hawley; W. Massey, Bromley, Kent. Commended, J. Dromley, Little Bolton, Lancashire.

DRAGONS.—First, J. Percival. Second, A. Boote, Crewe. Highly Commended, Rev. H. J. Stokes, Leek; J. Percival.

MAGPIES.—First, J. Hawley. Second, H. Yardley. Highly Commended, T. Martin, Manchester.

ANTWERPS.—First and Second, J. Hawley. Commended, J. Thompson; E. Hutton, Leeds.

ARCHANGELS.—First, S. A. Taylor, Sutton Coldfield. Second and Commended, H. Yardley.

ANY OTHER VARIETY.—First and Second Extra Prize for the best pen in the Barb and subsequent classes, J. Hawley. Second, H. Draycott (German Toy). Highly Commended, H. Draycott (trillbacks) H. Yardley.

Extra Prize to the Exhibitor gaining the greatest number of prizes for Pigeons, J. Hawley.

CANARIES.

BELGIAN (Clear Yellow).—First and Extra Prize for best Clear Yellow, Buff, or Variegated Belgian, S. Bunting, Derby. Second, — Warren, Macclesfield. Highly Commended, J. Austin, Leek. Commended, — Warren; — Green, Nantwich.

BELGIAN (Clear Buff).—First, — Warren. Second, S. Bunting. Highly Commended, H. Ashton; — Warren. Commended, — Masses.

BELGIAN (Variegated).—First, — Green. Second, — Laxson, Derby.

BELGIAN (Crested).—To be judged for best crest irrespective of colour.—First and Second, — Warren. Highly Commended, H. Ashton; — Warren.

NORWICH (Clear Yellow).—First and Extra Prize for best Norwich, — Bexon. Second, — Orme. Commended, — Pierey, Hanley.

NORWICH (Clear Buff).—First, — Bexon. Second, — Orme. Highly Commended, H. Ashton. Commended, — Pierey.

NORWICH (Variegated).—First, H. Ashton. Second and Highly Commended, — Bexon.

JONQUE.—First, H. Ashton. Second, S. Bunting. Highly Commended, — Warren; — Bunting. Commended, — Orme, Derby.

GREY.—First and Extra Prize for best bird in this and the previous class, S. Bunting. Second, — Warren, Macclesfield. Very Highly Commended, H. Ashton.

PIED MULE (Yellow).—First and Extra Prize for best Pied Mule, H. Ashton. Second, — Bexon.

PIED MULE (Buff).—First, H. Ashton. Second, S. Bunting. Very Highly Commended, — Orme.

GOLDFINCH.—First, — Pierey, Northwood. Second, H. Ashton.

MULE CANARY (Buff).—Prize and Extra Prize, — Lowndes, Hanley.

LINNET (Brown).—First, — Knapper, Hanley. Second, — Perry, Hanley. Very Highly Commended, — Wardle, Hanley. Commended, — Perry; S. Bunting.

Extra Prize to the Exhibitor gaining the greatest number of Prizes for Birds. — S. Bunting, Derby.

NORWICH (Yellow, bred in the Potteries).—Prize, J. B. Piercy.

NORWICH (Buff, bred in the Potteries).—Prize, J. B. Piercy.

RABBITS.

HEAVIEST.—First, C. Gravit, Thorne. Second, W. Bedson, Northwood. Highly Commended, T. Baker, Dresden.

LONGEST EARS.—First, W. Allison, Sheffield. Second, — Millington, York. Highly Commended, — Draycot, Leicester.

ANY VARIETY (Irrespective of length of ears or weight).—First and Second, — Millington. Highly Commended, W. B. Etches, Sale; R. Wise, Huntingdon. Commended, C. Gravit, Thorne; W. Allison, Sheffield.

The Judges were for *Poultry*: Rev. G. F. Hodson, North Petherton, near Bridgewater; Mr. C. Bulpin, Riverside, Bridgewater; and Rev. T. O'Grady, Hognaston Vicarage, Ashbourne; *Pigeons*: Mr. C. Bulpin, Riverside, Bridgewater; *Cage Birds*: Mr. Barnesby, Wilmet Street, Derby; *Rabbits*: Mr. S. Johnson, Etruria.

WHITEHAVEN POULTRY SHOW.

THE number of entries at this Show, held on the 7th, 8th, and 9th inst., was scarcely so great as on some former occasions, this year amounting to between six and seven hundred pens; but the quality of the birds generally was far superior to that of former years, most of the classes being good throughout. The management of the Show and the care taken of the poultry deserve our highest praise; green food, a luxury to poultry at this time of year, and soft food, being abundantly supplied.

The show of *Cochins* was particularly good, Mr. Mapplebeck's Buffs and the White ones of Mr. Smalley being first-rate; and the classes of these varieties were throughout far better than usual. Mr. Brierley's Partridge *Cochins* were also very perfect specimens. In the *Dorking* classes the cup was awarded to a singularly large well-fathered pen of Silver-Greys. The chicken *Spanish* class was far superior to the one for adult birds, many of the old cocks having the great defect of heavily corrugated faces, rendering them entirely blind. The *Game* fowls were very superior; Messrs. Fletcher, Wetherall, Ponton, Wilson, Julian, and Weeks obtaining their well-earned laurels in a very severe competition. In *Hamboroughs* the Golden-spangled were by far the most praiseworthy. Most of the *Game Bantams* were excellent, and some well-shown *Pelkin Bantams* were most interesting to visitors. The *Chaco Turkeys*, and *Ducks* were unexceptionally good, as were the generality of the *Pigeons* throughout large classes.

OPEN CLASSES.

COCHIN-CHINA (Cinnamon or Buff).—First, H. Mapplebeck, Woodfield, Moseley, Birmingham. Second, W. A. Taylor, Manchester. Third, Messrs. Gunson & Jefferson, Whitehaven. Highly Commended, Mrs. A. Wilkin, Boodle Rectory; C. W. Brierley, Middleton, Manchester; R. White, Broomhall Park, Sheffield; G. Shrimpton, Leighton Buzzard; H. Tomlinson, Birmingham. Commended, J. Poole, Ulverston. **CHICKENS.**—First, H. Mapplebeck. Second, C. Sedgwick, Ryddlesden Hall, Keighley. Third, Col. Stuart Wortley, Grove End Road, London. Highly Commended, C. W. Brierley; Messrs. Gunson & Jefferson; H. Tomlinson. Commended, W. A. Taylor.

COCHIN-CHINA (Partridge).—First, C. W. Brierley. Second, H. Lingwood, Bucklesham, Woodbridge, Suffolk. Third, J. Shortnose, Newcastle-upon-Tyne. Highly Commended, Miss E. A. Aglionby, Hlawhead. **CHICKENS.**—First, J. A. Taylor, Manchester. Second, C. Sedgwick. Third, T. M. Derry, Gedney. Highly Commended, Messrs. Bowman & Fearon, Whitehaven.

COCHIN-CHINA (White).—First and Cup, R. Smalley, Lancaster. Second, S. Sherwen, Whitehaven. Third, Rev. F. Taylor, Kirkandrew's Rectory, Longtown. Commended, W. F. Dixon, Gillhead, Whitehaven. **PALLETS.**—First, C. W. Brierley. Second, C. Sedgwick. Third, J. K. Fowler, Aylesbury. Highly Commended, A. H. Ventry, Northenden; Messrs. Gunson & Jefferson; Messrs. Bowman & Fearon; J. Poole.

BRAMMA FOOT.—First, W. Hargreaves, Bacup. Second, H. Lacy, Hobden Bridge. Third, Miss Aglionby. Highly Commended, K. Jopp, Aberdeen. **CHICKENS.**—First, H. Lacy. Second, R. White. Third, K. Jopp. Highly Commended, W. Hargreaves, Col. Stuart Wortley. Commended, Messrs. Bowman & Fearon. **PALLETS.**—First, G. Dixon, jun., Whitehaven. Second, Messrs. Bowman & Fearon. Third, W. Hargreaves. **DORINGS (Silver-Grey).**—First, R. D. Holt, Orsett Head, Windermer. Second, Miss Milne, Otterburn, Kelso. Third and Highly Commended, R. Smalley.

DORINGS (Any other variety).—First, J. White, Warlaby, Northallerton. Second, Messrs. Gunson & Jefferson. Third, W. W. Rutledge, Shortend, Kendal. **CHICKENS.**—First, R. Smalley. Second, T. Rogers, St. Helen's, Lancashire. Third, J. Parlett, Huntingdon. Highly Commended, J. Fox, St. Bees; D. Gellatly, Meiride; Messrs. Gunson & Jefferson. Commended, J. White. **PALLETS.**—First, T. Rogers. Second, J. Fox. Third, R. Smalley. Highly Commended, J. White; Messrs. Gunson & Jefferson. Commended, D. Hardie, Langholm.

SPANISH.—First, Miss Nelson. Second, J. Thresh, Bradford. Third, Messrs. Burch & Boulter, Sheffield. **CHICKENS.**—First, Miss Sidpath, Edinburgh. Second, Messrs. Bowman & Fearon. Third, J. Leeming, Broughton, Preston. **PALLETS.**—First and Cup, Miss Sidpath. Second, J. Wilson. Third, Messrs. Burch & Boulter. Highly Commended, J. Newton, Salsdon, Leeds; E. Brown, Sheffield.

FRENCH.—First and Third, Mrs. Wilkin, Boodle. Second, Messrs. Gunson & Jefferson. Highly Commended, E. Brown. Commended, J. K. Fowler.

GAME (Any description).—Cock.—Cup, First, and Third, J. Fletcher,

Stoneclough, Manchester. Second, Capt. Wetherall, Lodington, Kettering. Highly Commended, J. H. Wilson; J. Brough. *Cockerel.*—First and Cup, W. Boulton, Dalton-in-Furness. Second, J. Fletcher. Third, J. Gelderd, Kendal. Highly Commended, J. Poole. Commended, Capt. Wetherall; Mrs. Parker, Coalstaith, Brampton; J. Barrow, jun., Kendal. *Game (Black-breasted and other Reds).*—First and Cup, J. H. Wilson. Second, J. Fletcher. Third, W. Boulton. Highly Commended, R. Pickering, Carlisle; J. Barrow, jun.

GAME (Any other variety).—First, H. M. Julian, Hall. Second, J. Fletcher. Third, J. Brough. **PALLETS.**—First, J. Weeks, Boodle. Second, D. Gellatly. Third, J. H. Wilson. Commended, T. Mason, Green Ayre, Lancaster; D. Hardie.

HAMBOURG (Golden-spangled).—First and Cup, H. Pickles, jun., Earsby. Second, H. Beldon, Bingley. Third, E. Brierley, Heywood. Highly Commended, N. Marlor, Denton. Commended, J. Osdon, Hollingwood.

HAMBOURG (Silver-spangled).—First, H. Beldon. Second, H. Pickles, jun. Third, J. Fielding, Newchurch. Highly Commended, J. Smalley; J. Walker, Knaresborough. Commended, Messrs. S. & R. Ashton, Mottram.

HAMBOURG (Golden-pencilled).—First, H. Pickles, jun. Second, W. Bowe, Carlisle. Third, S. Smith, Northwram. Highly Commended, H. Beldon; T. Wrigley, jun., Tonge, Middleton; R. Burrows.

HAMBOURG (Silver-pencilled).—First, J. Preston, Altherton. Second, H. Beldon. Third, J. Walker.

HAMBOURG (Any variety).—*PALLETS.*—First, H. Beldon. Second, J. Ogden. Third, Messrs. Bowman & Fearon. Highly Commended, H. Pickles, jun.; R. Burrow.

ANY VARIETY NOT NAMED.—First, H. Beldon (Poland). Second, G. W. Boodley, Louth. Third, Mrs. Wilkin (Buff Poland). Commended, R. H. Nicholas, Newport, Monmouth.

SELLING CLASSES.—First, Messrs. Gunson & Jefferson. Second, J. Thompson, Bingley (Spanish). Third, J. Hinton, Boothstown Bridge, Manchester (Game Bantams). Highly Commended, Messrs. Gunson & Jefferson; Miss Spedding, Whitehaven; J. R. Robinson, Smeddall (Bantams); J. Cowman, Whitehaven (Douch Ducks); J. H. Wilson (White Cochins). Commended, Messrs. Bowman & Fearon; Miss Spedding; R. Smalley; J. Smith, Keighley (Black Spanish); G. Lell, Wigton (Game); J. White (Grey Dorkings); J. Hartley, Beckermott; — Irwin, Whitehaven (Polands); W. F. Dixon, Gillhead.

GAME BANTAMS.—First and Cup, W. Greaves, Bradford. Second, W. Parker, Clay Cross. Third, J. Parlett. Highly Commended, J. Oates, Stoney Road, Halifax; J. R. Robinson. Commended, S. Sherwen, Whitehaven; J. Parlett; G. Maples, Waverley, Liverpool. *Cock.*—First, W. A. Taylor, Manchester. Second, W. Boulton. Third, C. W. Brierley. Highly Commended, R. J. Wood; J. R. Robinson; J. Poole. Commended, W. Hudson, Rochdale; J. W. Morris, Darlington.

BANTAMS (Any variety).—First, T. Burgess, Brighouse. Second, W. A. Taylor. Third, J. R. Jessop, Hull. Highly Commended, Messrs. S. & R. Ashton; W. J. Cope, Barnsley; A. K. Briggs, Bradford. Commended, T. C. Harrison, Hull; W. A. Taylor; G. Maples.

DREKS (White Aylebury).—First and Cup, J. K. Fowler. Second, W. Pares, Ockbrook, Derby. Third, Messrs. Bowman & Fearon. Highly Commended, Lady J. Lindsay, Manchester Castle. Commended, D. Hardie.

DREKS (Bouen).—First, D. Hardie. Second, J. K. Fowler. Third, A. Dickinson, Whitehaven. Highly Commended, S. B. Stott, Rochdale; T. Honker, Revdize, Blackburn; E. G. Jones, Parton; Messrs. Gunson & Jefferson. Highly Commended, Rev. F. Taylor; J. J. Waller, Kendal.

DREKS (Any other variety).—First, T. C. Harrison. Second, C. W. Brierley. Highly Commended, H. Beldon.

GEES.—First, J. K. Fowler. Second, Messrs. Gunson & Jefferson. Third, Mrs. Birkett, Worlington. Highly Commended, J. Turner, Whitehaven.

TERKEYS.—First, Miss Borthwick, Flinaby. Second, J. Cowman. Third, J. Fox.

LOCAL CLASSES.

DORINGS.—Cock.—First and Cup, A. Thompson, Whitehaven. Second, J. Stirling, Bridgekirk, Co. Durham. Third, Messrs. Gunson & Jefferson. Highly Commended, J. Stirling; J. Fox; Messrs. Gunson & Jefferson. *Hen or Pullet.*—First, J. H. Wilson. Second, Messrs. Gunson & Jefferson. Third, J. Fox. Highly Commended, A. Thompson; J. Robertson, H. Harrook, Whitehaven.

COCHINS OR BRAMMAS.—Cock.—First and Cup, G. S. Dalzell, Whitehaven. Second, Miss Spedding, Whitehaven. Third, Messrs. Gunson & Jefferson. Highly Commended, Messrs. Bowman & Fearon; J. Robertson; Messrs. Gunson & Jefferson. Commended, G. Dixon. *Hens or PALLETS.*—First, Messrs. Gunson & Jefferson. Second, J. Richards. n. Third, W. Burnycat, jun., Corkiele. Highly Commended, Messrs. Gunson & Jefferson; W. Burnycat, Whitehaven; H. B. Lindsay, Manchester Castle. Commended, Mrs. Wilkin; G. S. Dalzell.

SPANISH.—Cock.—First and Cup, J. H. Wilson. Second, J. Hartley, Beckermott. Third, Messrs. Bowman & Fearon. *Hen or Pallet.*—First and Third, J. H. Wilson. Second, Messrs. Bowman & Fearon. Third, J. H. Wilson.

GAME.—Cock.—First and Cup, J. Brough, Ellenberha-st. Second, Messrs. Bowman & Fearon. Third, J. H. Wilson. Highly Commended, Jefferson Brough; J. H. Wilson. Commended, C. Fisher, Whitehaven. *Cockerel.*—First and Cup, J. H. Wilson. Second, Jefferson Brough. Third, J. Mitchell, Egremont. Highly Commended, J. H. Wilson. *Hens or PALLETS.*—First, J. Weeks, Boodle. Second, C. Fisher. Third, J. H. Wilson. Commended, Messrs. Bowman & Fearon.

HAMBOURG.—Cock.—First and Cup, E. G. Jones. Second, A. Briggs. Third, Messrs. Bowman & Fearon. Highly Commended, Messrs. Bowman & Fearon; J. Moore, Mireside. Commended, H. J. Nelson, Holborn Hill, Cumberland. *Hen or Pallet.*—First, J. H. Wilson. Second, H. J. Nicholson. Third, A. Briggs. Commended, Rev. H. Fox, St. Bees.

BANTAMS.—Cock.—First and Cup, J. Weeks. Second, Miss Spedding. Third, G. S. Dalzell. Highly Commended, Messrs. Bowman & Fearon; S. Sherwen. *Hen or Pallet.*—First, Miss Spedding. Second, J. Weeks. Third, Messrs. Bowman & Fearon.

DREKS.—First and Cup, Messrs. Bowman & Fearon. Second, Messrs. Gunson & Jefferson. Third, A. Dickinson. Highly Commended, C. Fisher; J. Cowman; E. G. Jones.

PIGEONS.

CARRIERS.—Cock.—First, R. H. Artindale, West Derby, Liverpool. Second, G. H. Roberts, Penwortham, Preston. Highly Commended, R. H. Artindale; H. Yardley, Birmingham. *Hen.*—First, G. H. Roberts. Second,

cond, F. Else, Westbourne Grove, London. Highly Commended, H. Yardley.

POUTERS.—*Cocks*.—First and Second, C. Cowburn, Calls, Leeds. Highly Commended, H. Yardley. *Hens*.—First and Second, J. Hawley, Bingley.

TUMBLERS (Almond).—First, J. Hawley. Second, F. Key, Beverley. Highly Commended, C. Cowburn.

TUMBLERS (Any other variety).—First, J. Hawley. Second, R. Whittaker, Bolton. Highly Commended, C. Cowburn.

JACOBS.—First, J. Hawley. Second, R. Thompson, Moresdale Hall, Kendal. Highly Commended, J. Thompson, Bingley; J. Towerson, Whitehaven.

TRUMPETERS.—First, J. Hawley. Second, J. Thackray, York. Commended, J. Thompson.

BABES.—First, G. H. Roberts. Second, J. Thompson. Highly Commended, T. Newall, Ashton-under-Lyne.

TURBITS.—First, J. Thompson. Second, R. Thompson. Highly Commended, H. Yardley.

HEELS.—First, H. Yardley. Second, J. Towerson.

FANTAILS.—First, J. Thompson. Second and Commended, H. Yardley.

ANY OTHER NEW OR DISTINCT VARIETY.—First, J. Hawley (Blue Priests). Second and Third, H. Yardley. Highly Commended, J. Thompson; J. Thresh (Ruff-footed Dutch Rollers).

SELLING CLASS (Any variety).—First, F. Key. Second, J. Thompson. Highly Commended, J. R. Jessop (Pouters); J. Hawley; G. Birkett, Whitehaven.

ANY VARIETY (Three pairs to be shown together).—First and Second, J. Towerson.

CANARIES.

BEIGIAN BUFF.—First, J. Thompson. Second, R. Hawman, Middlesbrough-on-Tees. Highly Commended, J. Williamson, Ulverston.

MCLE (Yellow).—First, Withheld. Second, J. Tyson, Frizington.

MCLE (Buff).—First, R. Hawman. Second, J. Thompson.

PIEBALDS.—First, J. Boulton, Ulverston. Second, R. Hawman. Commended, J. King, Frizington.

LIZARDS.—First, J. Hawman. Second, Capt. Donaldson, Whitehaven. Commended, J. Thompson.

RABBITS.

LOP-EARED.—First and Third, Messrs. Bowman & Fyson. Second, Miss E. H. Johnson, Carlisle. Highly Commended, Miss A. Barker, Bolton Hall, G.forth.

ANY OTHER VARIETY.—First and Second, Miss A. Barker.

The Geese, Turkeys, Ducks, and Pigeons were judged by Mr. R. Pickering, of Carlisle; and the rest of the classes by Mr. E. Hewitt, of Birmingham, and Mr. R. Tebbay, of Preston.

SELKIRK POULTRY SHOW.

The fifth Show of the Selkirkshire Society was held in the Volunteer Hall, Selkirk, January 8th and 9th, when the following awards were made by the Judges, James Dickson, Esq., North Park, Bradford; and J. Walker, Esq., Inverlathbrugh.

SPANISH.—First, D. Waugh, Melrose. Second, Miss F. Ridpath, Edinburgh. Third, W. Paterson, Langholm.

DORKINGS (Coloured).—First and Highly Commended, L. & J. Binning, Melrose. Second, G. H. Plummer, D. Keith. Third, W. Snowie, Philiphaugh. Commended, J. Simson, Fifehead; W. Fairbairn, Whitburn; Miss M. Brown, Philiphaugh.

COCHIN-CHINA.—First, Major Dickson, Midstream. Second, J. Stewart, Tulliebank, Dumbarton. Third, W. R. Park, Abbotsmills, Leith. Highly Commended, W. R. Park; J. Shattock, Newcastle.

BRAMA POULTRY.—First, J. Stewart. Second, W. R. Park. Third, G. H. Plummer. Highly Commended, D. Murray, Selkirk. Commended, J. Waugh, Selkirk.

HAMPSHIRE (Golden-pencilled).—First and Third, W. R. Park. Second, W. Bowe, Carlisle. Highly Commended, W. Scott, Galashiels; G. Walker, Selkirk.

HAMPSHIRE (Silver-pencilled).—First, J. Preston, Allertoun, Bradford. Second, W. R. Park. Third, G. Walker. Commended, W. Laurens, Yarm.

HAMPSHIRE (Golden-spangled).—First, A. Heald, Selkirk. Second, J. Preston. Third, R. Dickson, Selkirk. Highly Commended, J. Ness, Kirkcaldy. Commended, R. Dickson; E. Currie, Ayr.

GAME (Black or Brown Red).—First, D. Hardie, 57, Eves Lang, Inn. Second, H. M. Julian, Hull. Third, W. Kiddle, Newtown. Highly Commended, H. Goodall, Kirkcaldy. Commended, W. Brown, Selkirk; Lord Binning.

GAME (Any other variety).—First, H. Goodall. Second, T. Davidson, Third, H. M. Julian.

GAME BANTAMS (Black or Brown Red).—First and Third, W. Mahon, Jedburgh. Second, W. Hodgson, Darlington. Highly Commended, J. Roberts, Dunfermline. Selkirk; Miss Tait, Heatherlie, Selkirk; W. Scott, Jedburgh Black Red; J. Hardie.

GAME BANTAMS (Any other variety).—First, W. Mahon. Second, W. Scott (Pheas). Third, T. Stoddart, Selkirk.

BANTAMS (Any variety except Game).—First, F. L. Roy (Silver-faced Sebright). Second and Third, Lord Binning (Sebright).

DUCKS (White Aylesbury).—First, Sir J. Murray, Bart., Philiphaugh. Second, D. Hardie. Third, J. S. E. Fair, Overwell, Jedburgh. Highly Commended, G. D. Dryden. Commended, A. Hoggar, B. Mollet, Leshe, Fifehead; Lord Binning.

DUCKS (Brown).—First, D. Hardie. Second, W. Edgar, Dundalehaugh, Selkirk. Third, Mrs. Annie, Woll.

TURKEYS.—First, T. L. Jackson, Bush of Eves, Cambridge. Second and Third, Lord Binning (Cambridge). Commended, Mrs. Annie, American.

COTTAGE CLASS (Any variety).—First, W. Miller (Dorkings). Second, G. Turnbull, Dundalehaugh, Selkirk. Third, J. Graham (Golden-spangled). Highly Commended, J. Judge, Selkirk (Silver-spangled); R. Edgar (Silver-pencilled); J. Gardiner (Brown Red Game); W. Miller (Dorkings); W. Inglis, Selkirk. Commended, A. Heald, Ayr (Gold-spangled); W. Edgar, Heatherlie (Brown Red Game); J. Taylor, Selkirk (Golden-pencilled).

SELLING CLASS.—First, T. L. Jackson (Dorkings). Second, T. Musgrave, Third, W. Edgar (Rosen Ducks). Highly Commended, W. Linton, (Brahma Pouter); J. Musgrave, Longtown; F. L. Roy, Nenthorn (Duckwing Game); W. Turnbull (Golden-spangled). Commended, G. Walker (Silver-pencilled); W. Tait (Brown Red); F. L. Roy (Black Red).

SWEETFARE FOR BANTAM COCK.—First, J. L. Brown, Selkirk. Second, W. Mahon. Third, F. L. Roy (Duckwing). Highly Commended, W. Scott; W. Easton.

PIGEONS.

TUMBLERS (Short-faced).—Prize, J. E. Spence, Musselburgh. **TUMBLERS** (Any other variety except Short-faced).—First, J. Bell, Newcastle-on-Tyne. Second, J. Simson. Equal Second, J. Ballantyne, Selkirk.

FANTAILS.—First, W. R. Park. Second, W. Cheyne, Selkirk. Highly Commended, J. Grant.

POUTERS.—First, J. Bell. Second, J. Grant. Very Highly Commended, J. Grant. Highly Commended, J. Simson; W. Cheyne; K. Paterson.

JACOBS.—First, R. Paterson. Second, R. Davidson. Highly Commended, J. Spencer, J. Bell.

SCOTS.—First, J. Davidson. Second, R. Paterson. Highly Commended, R. Paterson; F. L. Roy. Commended, W. Cheyne.

GRAYS.—First, R. Paterson. Second, W. R. Park. Highly Commended, T. Spence; W. R. Park. Commended, J. Bell.

TRUMPETERS.—First, R. Paterson. Second, W. Cheyne. Commended, T. Little, Selkirk; W. R. Park.

ANY OTHER VARIETY.—First, J. Bell. Second, W. Cheyne. Highly Commended, W. Cheyne.

SELLING CLASS.—First, W. R. Park (Fantails). Second, R. Paterson (Jacobin). Third, J. Grant (Pouters).

NORTHERN POULTRY CLUBS SHOW.

The Exhibition of Poultry and Pigeons was held on the 1st and 2nd of January in the Artillery Gymnasium, Queen Street, Aberdeen. The Show on the whole was admitted to be the best ever held in Aberdeen, or the North of Scotland. The entries for Poultry and Pigeons amounted in all to 500, including competitors from all parts of England and Scotland.

The *Cochins* were considered very good, both in numbers and quality. Mr. Anderson's cockerel and pullet, which gained the first prize in the cup, were very superior. Mr. Pashley's birds, which only, however, arrived the second day of the Show, would have pressed very hard for the highest honors. The *Spanish* fowls were in fair feather and on the whole remarkably good; those exhibited by Mr. Ridpath, of Edinburgh, were especially so. *Dorkings* were a strong class, and, although most of the other breeds were short in feather, there were many very good pens; and the coloured birds were excellent. *Cochins* were a fair class, the single cock which gained the cup being a very fine bird, pecking the best in the show. We think the only error in judgment was in the *Cochin* cockerel and pullet class, a very fine pen of Mr. Stuart's, of Glasgow, being passed over without even a notice. The *Brahmas*, however, were the great feature of the Show, being numerous and of admirable quality. The birds shown by Mr. Jopp, who won the cup, were the best we have ever seen exhibited. *French Fowls* were shown in considerable numbers, the most of the prizes falling to B. C. Urquhart, Esq., of Midburn, who exhibited some very fine specimens of *Houdans* and *Croco-Corps*. *Hens* were a slow of themselves, ninety-one pens being exhibited; the cup in this class was won by a very fine pen of *Silver-spangled* *Hens* belonging to Mr. Beldon. In the class for Any other variety, with the exception of Mr. Beldon's first-prize pen, the birds were poor in quality. *Bantams* were a poor show; exception must, however, be made of the single Game Bantam cock belonging to Mr. Anderson, of Melde, which was a very fine bird.

Ducks were a good and very good, the first-prize gander being the best bird we have seen exhibited this season.

The show of *Pigeons* was not equal in point of numbers to former shows here, but the quality of the birds was superior. The classes of *Pigeons* were remarkably well represented, especially the *Blues* and the *White*; the latter in Mr. McE's medal pair (and which beat the first-prize pair at the Glasgow Show), amongst the former, deserves special notice. The *Cocks* were on the whole fair, Mr. Fulton's *Dun* cock which was first, and Mr. McGee's *Black* hen, were the finest specimens of their kind ever shown here. The *Fantails* were very numerous and good. *Bantams* were a fine class, and the others were all of fair merit.

The arrangements of the Show were of the most complete and satisfactory character, and reflected much credit on the Committee and Secretary.

GAME (Any colour).—*Cocks*.—First, T. Watson, Crieff. Second, G. Howie, Ewe House, Bairs. Third, J. Anderson, Ruthven House, Meigle. N.B. *Hens*.—First, J. Anderson. Second, W. Hay. Third, J. M'Pherson. *Cochins*.—First and Cup, J. Anderson. Second, W. Roberts, Thornhill, near Burnley. Third, W. Tait, Heatherlie, Selkirk. Commended, J. M'Pherson; S. Smith, Crieff.

SPANISH.—*Cocks*.—First, Messrs. Brown & Cochrane, Perth. Second, J. Ferrier, Woodside. Third, T. Knowles. *Hens*.—First, A. Ridpath, Edinburgh. Second, S. Mitchell, Golden Place, Aberdeen. Third, W. Hay. Highly Commended, W. McE; Messrs. Brown & Cochrane. *Chickens*.—Cup, F. James, Peckham Rise. Second, A. Ridpath. Third, W. McE. Highly Commended, S. Mitchell.

DORKING (Silver-Grey).—*Cocks*.—First, W. McE. Second, T. Knowles, Jun. Third, A. G. Pirie, Stoneywood, near Aberdeen. *Hens*.—First, W. McE. Second, T. James, Bridge Haugh, Stirling. Third, A. Farquhar, Elrick. Highly Commended, A. F. Williamson, Gasliehen Mains, Blackburn. Aberdeen; J. Gordon, Inverurie. *Chickens*.—First, W. McE. Second, T. James. Third, J. Milne, Radio House.

DORKING (Any other colour).—*Cock*.—First, J. Gordon. Second, T. Knowles, jun. Third, D. Gellatly, Migle. *Hens*.—First and Cup, J. Gordon. Second, W. McE. Third, D. Gellatly. *Chickens*.—First, J. Anderson. Second, T. Raines. Third, J. Gordon. Highly Commended, J. Clark, Forchabers.

COCHIN-CHINA (Any colour).—*Cock*.—Cup, G. Murray, Aberdeen. Second, B. C. Urquhart, Meldrum. Highly Commended, J. Young, Aberdeen. *Hens*.—First, Mrs. Carnegie, Redbank, Fordoun. Second and Third, G. Murray. *Chickens*.—First and Second, G. Murray. Third, L. Crick-shank, Old Meldrum.

BRAHMA POOTRA (Any colour).—*Cock*.—Cup and Second, K. Jopp, Aberdeen. Third, C. B. Fisher. Commended, Mrs. Farquharson, Inveraild; Mrs. Stronach, Sunnybank, Aberdeen. *Hens*.—First, J. Stuart, Thistlebank, Helensburgh. Second, K. Jopp. Third, F. W. G. Gray, Aberdeen. Highly Commended, T. Raines; K. Jopp; J. Chalmers, Granton Lodge. *Chickens*.—First, Second, and Third, K. Jopp. Highly Commended, Mrs. A. Fisher.

HOUDAN, CRIVE-CEUR, OR LA FLICHE.—*Cock*.—First and Third, R. C. Urquhart. Second, R. O. Farquharson, Haughton, Alford. Highly Commended, F. W. G. Gray. *Hens*.—First and Second, B. C. Urquhart. Third, R. O. Farquharson.

HAMPSHIRE (Gold or Silver-pencilled).—*Cock*.—First, J. D. Stone, Second, J. Still, Spittal. Third, R. McGregor, Perth. Highly Commended, D. Normand; B. C. Urquhart; H. Pickles, jun., Early. Commended, D. Normand. *Hens*.—First, H. Pickles, jun. Second, J. Hay, jun., Aberdeen. Third, J. Bowe, Carlisle. Highly Commended, R. McGregor; D. Normand.

HAMPSHIRE (Golden-spangled).—*Cock*.—First, P. Campbell, Oldwhat, New Deer. Second, Mrs. Farquharson. Third, H. Pickles, jun. Highly Commended, D. Walker, Aberdeen; H. Beldon, Goitstock, Bingley; T. Mushgrove, Longton, Carlisle. *Hens*.—First, H. Pickles, jun. Second, J. F. Loverside, Newark. Third, Mrs. Farquharson. Highly Commended, Mrs. Brown, Abercainny, Crieff; H. Beldon.

HAMPSHIRE (Silver-spangled).—*Cock*.—First, W. France, jun., Crieff. Second, J. Hay, jun. Third, H. Pickles. Highly Commended, H. Beldon. *Hens*.—Cup, H. Beldon. Second, H. Pickles, jun. Third, J. Hargreaves, Carlisle. Highly Commended, W. France, jun.

ANY OTHER VARIETY.—First, H. Beldon. Second, W. McIntosh, Balmagask, Nigg.

GAME BANTAMS (Any colour).—*Cock*.—First, J. Anderson. Second, J. J. Consins, Allerton, near Leeds. Third, G. Robertson, Aberdeen.

GAME BANTAMS (Any colour).—First, R. Macgregor. Second, J. Anderson. Third, G. Dalgarno, Strathgill, Aberdeen. Highly Commended, P. Campbell.

BANTAMS (Any other variety).—First, T. Watson, Crick. Second, H. T. Paterson, Kenfield, Aberdeen. Third, M. W. H. Peple, Perth.

DUCKS (Any variety).—First, J. Anderson. Second and Third, Mrs. Stronach. Highly Commended, A. Haggart, Leslie.

DUCKS (Any other variety).—First, J. Anderson. Second, Mrs. Carnegie. Third, D. Gellatly. Highly Commended, A. Farquhar.

TURKEYS.—First and Second, Mrs. Carnegie. Third, Mrs. Stronach.

GESE.—First, Mrs. Carnegie. Second, B. C. Urquhart. Third, A. Farquhar.

SELLING CLASS.—First, T. Knowles, jun. Second, P. Campbell. Third, B. C. Urquhart. Highly Commended, W. Pyper, Bellshiel; T. Macgregor.

PIGEONS.

POUTERS (White).—First, R. Fulton, Duffield, London. Second, F. McCrae, Aberdeen. (Blue).—Medal, W. McE. Aberdeen. Second, R. Fulton. (Any other colour).—First, R. Fulton. Second, J. Sharp, J. B. Stone.

CARRIERS.—Medal, W. McE. Second, R. Gunn, Dundee.

POUTERS (White).—*Cock*.—First, R. Fulton. Second, W. McE. *Hens*.—First, J. Grant, Corstorphine, Edinburgh. Second, W. McE.

POUTERS (Blue or Black).—*Cock*.—First, R. Fulton. Second, J. Grant. *Hens*.—First, R. Fulton. Second, W. McE.

POUTERS (Any colour).—First, R. Fulton. Second, J. Grant. *Hens*.—First, J. Grant. Second, R. Fulton.

CARRIERS (Any colour).—*Cock*.—First, R. Fulton. Second, F. McCrae. *Hens*.—First, R. Fulton. Second, F. McCrae.

TUMBLERS (Almond).—First, R. Fulton. Second, J. Baillie, Bellevue, Aberdeen.

TUMBLERS (Any other colour).—First, R. Fulton. Second, J. Grant.

FANTAILS (Any colour).—First, J. Grant. Second, J. Rae. Third, J. Baillie. Highly Commended, J. Sharp.

JACOBINS (Any colour).—First, J. Baillie. Second, E. E. M. Boyd, Greenhill, Rochdale.

BARBS (Any colour).—First, W. McE. Second, R. Fulton.

TRUMPETERS (Any colour).—First, J. Grant. Second, J. Baillie.

TURBITS (Any colour).—First, J. Bell, Newcastle-on-Tyne. Second, J. Simpson, Bright n, Durris.

OWLS (Any colour).—First, J. Bell. Second, J. Sharp.

DRAGONS (Any colour).—First, J. Bell. Second, J. Sharp.

NUNS OR MAGPIES (Any colour).—First, J. Sharp. Second, J. Baillie.

ANY OTHER VARIETY (Any colour).—First, J. Sharp. Second, A. Cowie, Crambleybank, Ellon.

The Judges were, for *Pouter*, Mr. T. Challenor, Barlborough, Chesterfield; and Mr. John Martin, Linton Park, Staplehurst, Kent.

For *Pigeons*, Mr. J. H. Frame, Overton, Carlisle.

FIFE AND KINROSS ORNITHOLOGICAL SOCIETY'S EXHIBITION

THE annual Exhibition of the Fife and Kinross Ornithological Society was held in the Corn Exchange, Kirkcaldy. The number of specimens far exceeded that shown in any former year, and many of them were of very high merit. The Poultry consisted of upwards of 250 pairs. There were nearly fifty cages of Pigeons, and 141 specimens of Canaries. The prizetakers were:—

SINGLE COCKS (Any variety).—*Game*.—First, H. Goddall, Kirkcaldy. Second, A. Penman, Kelty. Third, H. Lawrie, Markinch. *Dorking*.—First, T. Raines, Bridge Ham, Stirling. Second, D. Gellatly, Melrose. Third, D. Normand, Kennoway. Highly Commended, J. L. Gow, Birtley.

Hon. Miss E. de Flahault. *Cochin*.—First, W. Morris, Aberdeen. Second, W. B. Park, Melrose. Third, Mrs. Oswald, Dornkirk. *Brahma*.—First, J. Macmillan, Edinburgh. Second, D. Gellatly. Third, J. I. Loverside, Newburgh-Trent. *Hampshire*.—First, A. Pratt, Kirkcaldy. Second, R. Thomson, Muttonhall, Kirkcaldy. Third, R. Stewart, Kelty. Highly Commended, A. W. Lenthall, Leslie. *Bantam*.—First, J. H. Gray, Jedburgh. Second, Hon. Miss E. de Flahault. Third, D. Talbot. Highly Commended, Mrs. Oswald.

GAME (Red).—First, A. Drummond, Glasgow. Second, G. Jamieson, Forfar. Third, Withheld. *Chickens*.—First, G. Mustard, Airth. Second, R. Stewart, Kelty. Third, D. Hard, Cluny.

GAME (Gray and other).—First, H. Goddall. Second, T. Baird, Bankhead, Kirkcaldy. Third, L. Clifton. Kirkcaldy. *Chickens*.—First, H. Goddall. Second, D. Pennington, Dysart. Third, J. Pennington, Dysart.

DORKING.—First, Hon. Miss E. de Flahault. Second, D. Talbot, Dundee. Third, D. Gellatly. *Chickens*.—First, T. Raines. Second and Third, Hon. Miss E. de Flahault.

COCHIN (Any variety).—First and Second, Mrs. Oswald. Third, W. R. Park.

BRAHMA POOTRA.—First, T. Raines, Stirling. Second, withd. Third, Hon. Mrs. Montgomery, Bankhead, Cupar-Fife.

SPANISH.—First, J. Macmillan. Second, J. Craig, Forfar. Third, A. Robertson, Burntisland.

HAMPSHIRE (Spangled).—First, W. Kiddle, Cowdenbeath. Second, H. Goddall. Third, R. Stewart, Kelty. Highly Commended, A. Penman.

HAMPSHIRE (Pencilled).—First, R. McGregor, Perth. Second, R. Thomson. Third, A. Pratt. Highly Commended, D. Normand.

GAME BANTAM (Any variety).—First, Hon. Miss E. de Flahault. Second, Mrs. Henderson. Third, A. Robertson.

BANTAM (except Game).—First, J. Rutherford, Neckenzie, Auchtermuchty. Second, D. Brown. Third, G. W. Borthwick, Leath, Lincolnshire.

ANY OTHER BRED.—First and Second, Hon. Miss E. de Flahault. Third, J. L. Gow, Perth.

DUCKS.—First, A. Haggart, Leslie. Second, A. Couper. Third, B. Mollett.

SELLING CLASS (Any breed).—First and Second, H. Goddall. Third, D. Normand.

CORN POULTRY SHOW.

THE eighth Exhibition of the South of Ireland Poultry, Pigeon, Cage and Song Bird Association was held in the Athenaeum on the 4th inst., and, so far as the preceding Shows of this useful Society have been concerned, it was the essential of quality, variety, and number. The pure birds were noble pairs. The *Pigeon* department, always very full, was even more numerously represented than at any previous Show. The song bird department included Canaries, Linnets, Blackbirds, Thrushes, Nightingales, Larks, Finches, &c., a collection as beautiful as it was interesting.

The chief attraction of the Exhibition was the splendid collection of birds exhibited by Mr. Carlott, of Castleconnell. This gentleman, whose well stocked aviaries are so well known among connoisseurs, had a selection including three Golden Eagles—magnificent birds—White Pheasants, Golden Pheasants—exceedingly beautiful birds, Kalage, Silver, Bohemian, Chinese, Pied, Hybrid, and Common Pheasants, all superb specimens of their several classes, besides a noble pair of Black Australian Swans, a pair of Japanese Pua fowl, a number of Peregrine Falcons, with hoods and bells; a Goshawk, an Iceland Falcon, a Virginian Owl, a trained Cormorant, a laughing Kingfisher, and a number of Blue, Red, and Yellow Macaws, Cockatoos, Parrots, Parakeets, &c. Among the Cockatoos was one remarkable bird, sombre and sage as Poe's raven, but of snowy whiteness, who sat thoughtfully on the high perch in the hall, at intervals putting a series of peremptory inquiries to his keepers. This remarkable bird was had by Mr. Corbett, twenty years ago in this city, from Mr. Henry Keating, who stated the bird was then close on thirty years old, so that the feathered patriarch must have seen a full half-century, and was yet hale and talkative enough to see many another year. The Goshawk, a fine bird, hooded and belled, and, with an atmosphere of chivalry and tournament about him, was presented to Mr. Corbett by a hawking noble in Paris, and had all the graces of his species, his owner frequently killing rabbits with him. Mr. Corbett offered nothing for competition.

The arrangements of the Show were capital, and among not the least attractive features of the Exhibition were the unique cages in which the song birds were caged, some of these being remarkably attractive in appearance and design. The following is the prize list:—

SPANISH.—First, A. Cowie, Ellon. Second, R. P. Williams, Comrie, and A. C. Cooper, Glasgow. First, Miss D. Conroy-Drew, Seafield, A.C. myn, jun. Highly Commended, Miss De Courcy-Drew.

DORKING.—Cock. First and Second, R. P. Williams. Third, E. Pike.

DORKING (Spang-Gow).—First and Second, Mrs. Warburton. Third, A. E. Lush. Highly Commended, Mrs. Warrington. Commended, Mrs. Warburton; T. O'Grady; Miss A. E. Pike; F. Haddon.

DORKING (White).—First, J. C. Perry. Second and Commended, Countess of Dundee.

COCHIN (Duff or Lark).—First, F. W. Curthorpe. Second, Mrs. Hay. Third, R. W. Doyle. Commended, H. L. Tivy.

COCHIN (Partridge).—Game. First, F. C. Cooper. Second, C. F. Johnston (Partridge). Commended, R. P. Williams.

COCHIN (Lark).—First, F. W. Curthorpe; Miss S. L. Pike; H. L. Tivy. Second, A. W. Shaw.

GAME (Black or Brown).—First, T. H. Marshall, Birtley. Second, R. Clive, Comrie, J. C. Cooper.

GAME (Duckwing or other variety).—First, T. H. Marshall, Birtley. Second, A. E. Allen (Duckwing). Third, N. W. Roche, Duff, Fife.

BRAHMA POOTRA.—First, T. Haddon. Second, Mrs. Warburton.

Third, A. W. Shaw (Light). Highly Commended, R. W. Boyle (Dark).
 Commended, A. W. Shaw (Light); Mrs. Dring.
CRÈVE CŒURS.—First and Cup, J. C. Fitzgerald. Second, J. C. Cooper.
HOUDEANS.—First, J. C. Cooper. Second, A. W. Shaw. Third and Highly Commended, F. W. Pim.
LA FLECHE.—First, A. W. Shaw. Second, J. C. Cooper. Commended, C. Langley; J. C. Cooper; C. F. Staunton.
POLANDS (White-crested).—First and Second, Miss De Courcy Drexler. Highly Commended, J. C. Cooper. Commended, R. P. Williams.
POLANDS (Spangled).—First, J. C. Cooper. Second, F. W. Pim (Silver). Highly Commended, Mrs. Dring (Gold); J. C. Cooper; R. P. Williams (Gold). Commended, Mrs. Dring; R. P. Williams.
HAMELINGS (Spangled).—First, J. C. Cooper. Second, R. P. Williams (Silver, double-crested). Commended, Countess of Bandon.
HAMBURGERS (Pencilled).—First, C. F. Staunton (Gold). Second, A. Murray, jun. (Gold-pencilled). Highly Commended, J. C. Perry (Gold); T. O'Grady.
GAME BANTAMS.—First, J. C. Cooper. Second, N. W. Roche (Duckwing). Highly Commended, J. Jeffries (Black Red); N. W. Roche (Black Red); A. E. Ussher (Black Red); W. D. Allen (Duckwing). Commended, W. D. Allen (Duckwing).
BANTAMS (Sulphur or other variety).—First, A. W. Shaw (Black). Second, Hon. A. C. E. Roche (Japanese). Third, Hon. A. C. E. Roche.
ANY OTHER VARIETY.—First and Second, J. C. Cooper (Malay and Sultans). Third, C. F. Staunton (Black Ureda). Highly Commended, Countess of Bandon (Silky Bantams). Commended, Mrs. Dring (Grey Guelthers); F. W. Zurichst (Sultans); Hon. Mrs. H. E. Bernard (Sultans).
TURKEYS.—First and Third, J. C. Cooper (Cambridge). Second, Mrs. Clements (Norfolk). Highly Commended, Mrs. Clements (Norfolk); H. Briscoe (Cambridge). Commended, J. C. Perry.
GESE (White).—First and Commended, J. C. Cooper (Emblen). Second, Mrs. Warburton. Highly Commended, Mrs. Warburton; E. Pike (Danubian).
GESE (Coloured).—First, A. E. Ussher (Toulouse). Second, J. C. Cooper (Toulouse). Highly Commended, A. E. Ussher (Toulouse); Rev. J. O'Sullivan (Chinese); E. Pike (Toulouse); J. Howard (Chinese); Dr. Parker (Chinese).
DUCKS (Aylesbury).—First and Third, J. C. Cooper. Second, J. T. Wakeham. Highly Commended, R. P. Williams.
DUCKS (Rouen).—First and Second, R. P. Williams. Third, J. C. Cooper.
ANY OTHER VARIETY.—First, R. P. Williams (Pintail). Second, Dr. Parker (Muscovy). Highly Commended, R. P. Williams (Shell Ducks); T. Babington (Widgeon, Mallard, and Duck).
SPECIAL PRIZES.
 The Society's silver cup, for the greatest number of points, J. C. Cooper.
 Silver medal presented by Mrs. Lyons, for the best pen of fowls in the Exhibition, Houdeans, La Fleche, and Crève Cœurs excepted, J. C. Cooper.
 Silver medal presented by F. W. Zurichst, Esq., Dublin, for the best pen of Crève Cœur, Houdean, or La Fleche, — Fitzgerald.
POUTERS (Black).—*Cocks.*—First and Second, J. Montgomery. Highly Commended, Dr. Harvey; J. H. Perrott. Commended, Dr. Harvey.
Hens.—First, Second, Highly Commended, and Commended, J. Montgomery.
POUTERS (Blue or Silver).—*Cocks.*—First and Second, J. Montgomery. Highly Commended, Dr. Harvey; J. Montgomery; J. H. Perrott. Commended, Dr. Harvey. *Hens.*—First and Second, J. Montgomery. Commended, J. Montgomery; J. H. Perrott.
POUTERS (Red or Yellow).—*Cocks.*—First and Second, J. Montgomery. Highly Commended, J. Montgomery; Dr. Harvey. *Hens.*—First, Second, and Highly Commended, J. Montgomery (Red and Yellow). Commended, J. H. Perrott (Red).
POUTERS (White).—*Cocks.*—First, Dr. Harvey. Second, J. Montgomery. Highly Commended, J. H. Perrott. Commended, J. Montgomery. *Hens.*—First, J. Montgomery. Second and Commended, Dr. Harvey.
POUTERS (Mead or other colour).—First, Second, Highly Commended, and Commended, J. Montgomery. *Hens.*—First and Second, J. Montgomery.
CARRIERS (Black).—*Cocks.*—First and Second, Dr. Harvey. Highly Commended, H. L. Tivy; G. A. Wherland. *Hens.*—First, Dr. Harvey. Second, J. Montgomery. Highly Commended, G. A. Wherland. Commended, G. A. Wherland.
CARRIERS (Dun or other).—*Cocks.*—First, G. A. Wherland. Second, J. Jeffries. *Hens.*—First, Dr. Harvey. Second and Highly Commended, G. A. Wherland.
TUMBLERS (Short-faced Almonds).—First and Second, Dr. Harvey.
TUMBLERS AND KITES (Short-faced).—Prize, Dr. Harvey.
TUMBLERS (Mottles or other colour).—Prize, J. F. Blennerhassett.
TUMBLERS, BALDS, OR BEARDS (Short-faced).—First and Second, J. F. Blennerhassett (Blue Beards).
TUMBLERS, BALDS, OR BEARDS (Common).—First, J. F. Blennerhassett. Second, J. Pike.
TUMBLERS (Common, any other colour).—First, H. L. Tivy. Second, J. H. Perrott.
BARDS (Black or Dun).—First and Second, J. Montgomery. Highly Commended, J. H. Perrott. Commended, R. Lane.
BARDS (Any other colour).—First, J. Montgomery (Yellow). Second, G. A. Wherland. Highly Commended, J. H. Perrott (Yellow). Commended, J. Jeffries; J. F. Blennerhassett; R. Lane (Red).
JACOBS (Red or Yellow).—First, J. H. Perrott (Red). Second, J. Pike.
JACOBS (Any other colour).—Prize, T. O'Grady.
FANTAILS (White).—First, R. Lane. Second, T. O'Grady. Highly Commended, E. & J. M'Crea; J. H. Perrott. Commended, J. Pike.
FANTAILS (Any other colour).—First and Commended, J. F. Blennerhassett (Black). Second, J. Pike.
OWLS (Blue or Silver).—First, J. Jeffries (Blue). Second, J. Pike. Highly Commended, J. F. Blennerhassett. Commended, Mrs. Warburton.
OWLS (Any other colour).—First, J. Montgomery. Second, J. H. Perrott.
TRUMPETERS (Mottled).—First, J. H. Perrott. Second, J. F. Blennerhassett.
TRUMPETERS (Any other colour).—First, J. Montgomery (Black). Second, J. H. Perrott.
TREBLES.—First and Second, J. F. Blennerhassett. Commended, R. Lane.

NUNS.—First and Second, J. F. Blennerhassett.
MAGPIES.—First, T. O'Grady. Second and Commended, J. F. Blennerhassett.
ANY OTHER VARIETY.—First and Second, J. Montgomery (Lace Fantails, and Silver Runts). Highly Commended, H. & J. M'Crea (Austrian Pouters); J. F. Blennerhassett (Maned). Commended, J. F. Blennerhassett (Brunswicks and German Ice).

Silver cup for the greatest number of points won in all classes, J. Montgomery.

Silver medal for the best pair of Pouters, J. H. Perrott.

SWEEPSTAKES FOR PIGEONS HATCHED IN 1897.—*Pouter.*—Prize, J. Montgomery (Red). Highly Commended, Dr. Harvey (White). *Carrier.*—Prize, Dr. Harvey.

SONG BIRDS.

CANARIES (Yellow without Crest).—First and Second, J. Hodder. Highly Commended, J. Hodder. Commended, M. McCarthy, jun.

CANARIES (Yellow with Crest).—Prize, Mrs. Hodder.

CANARY (Green Coloured or other).—First, A. Veitch. Second, Mrs. Hodder. Highly Commended, M. McCarthy, jun. Commended, J. Hodder.

GOLDFINCH MILES.—First, Mrs. Hodder. Second, W. P. Harris. Highly Commended, P. Cronin. Commended, Hon. E. B. Roche.

LINNET MILES.—First, J. A. Ross. Second, M. McCarthy, jun. Highly Commended, W. P. Harris. Commended, T. Walsh.

BLACKBIRDS.—First, D. Sullivan. Second, Mrs. Hodder.

THRUSHES.—First, Mrs. Hodder. Second, D. Sullivan.

WOODPECKERS.—Prize, J. O'Connor.

SYLVIANS.—First and Second, J. Lennie. Highly Commended, Mrs. Hodder. Commended, J. Lennie.

BULLFINCHES.—First, Mrs. Perry. Second, Mrs. Hodder.

GOLDFINCHES.—Prize, Mrs. Hodder.

LINNETS.—First, Mrs. Hodder. Second, E. Linahan.

The Judges were for *Pouter*: Mr. Tegetmeier, of London; *Pigeons*: Mr. P. H. Jones; *Other Birds*: Mr. Parker. — *Cork Examiner*

LEIGHTON BUZZARD POULTRY SHOW.

THE Corn Exchange, in which this Show was held, is everything that could be desired for a poultry show, and the arrangements throughout were good. The Ipswich pens were engaged, and the Exhibition was exceedingly well supported; in fact, the attendance quite exceeded the hopes of those gentlemen through whose endeavours this meeting originated. The silver cups given as principal prizes were very chaste in design, and certainly were quite of the value represented.

On referring to the prize list, which we published last week, omitting this report from want of space, it will be seen that the competition embraced many birds of the very highest character from the most noted breeders; and, as a whole, it very rarely happens that in a first show there is so much merit in the generality of the classes. In Grey *Duckings* the Show was especially good, Mrs. Seamons taking the first and third prizes, and W. Denison, Esq., the second position. The *Spanish* class was extraordinarily good, Francis James, Esq., exhibiting two pens of birds that together proved one of the most attractive features of the Show. The *Cochans* were exhibited in one general class, open to any variety. Mrs. Clarke's White ones were of especial merit; in fact, this lady's very large contributions of poultry exclusively of white feather met with the approbation of every one. The peculiarly good condition and spotless purity of plumage that, without a single exception, the whole of this lady's birds possessed, was most creditable to the home management, and formed a remarkable feature of the Show. *Brahmas* were well shown, the Hon. Miss Douglas Pennant securing the silver cup, in rather a large class, with a very superior pen that had travelled from so distant a spot as Bangor for this meeting expressly. The *Hamburghs* were the most deficient in merit of any classes in the Show, though the *Polands* and *French* fowls made ample amends. The *Boston* classes were excellent, a pen of very perfect Black-brasted Reds belonging to Mr. Jeffries, of Ipswich, being the Bantam cup-winners.

One of the greatest points of excellence in the Exhibition was the very close competition in the *Turkey*, *Geese*, and *Duck* classes; and when we add that Mrs. Seamons, Mr. J. K. Fowler, and Lady Margaret Maedonald, with many others of our most noted breeders, had contributed their best birds, it is scarcely necessary to remark that the birds were first-rate. Of *Pigeons* there was a very good general collection, the Carriers and Pouters being especially good.

In the Extra Stock classes the Silver Pheasants exhibited by Baron Rothschild were in extraordinarily fine feather, but proved so excessively wild as to detract sadly from the pleasure of visitors in seeing them. It was evident they were quite unaccustomed to strangers. Among the *Pigeons* were shown some Red and some Black Swallows, worthy of a position at any meeting. The weather was cold but bracing, and the novelty of the sight kept the Corn Exchange constantly well filled.

ULVERSTON POULTRY SHOW.

THIS was held on the 1st and 2nd inst. in the Victoria Concert Hall, and in point of entries was a success, though, owing to other shows occurring at the same time, it doubtless suffered to some extent.

Spanish formed a moderate class, the hens in all the pens being much superior to the cocks.

Duckings were few in number, and rather poor.

Game fowls were the leading feature of the Show, there being seven

classes, and upwards of eighty entries. Of these many pens were most excellent. In Reds Mr. Fletcher won with an excellent pen of Brown Reds, to which also was awarded the silver cup for the best pen in the classes for Reds, Duckwings, and Any other variety; but the other birds in this class were not of any note. The first-prize Duckwings, though best, were not good in colour; the second were good; but those forming the third-prize pen were so very small as to almost destroy their chance, though of rare excellence in colour. The class for Game of any other variety was a decided failure, and only one second prize was awarded, and that to a Muffed or Bearded pair. One pen contained a pair of birds beautifully bedaubed with magenta about the eyes and face, doubtless to destroy the sickly appearance of the flesh; but the operator had overshot his mark, and the result was a disqualification.

In Buff *Cochin-Chinos* the first-prize pen contained a remarkably fine hen, and the second a cock which ought to be mated to the former. Of Brown and Partridge there were some fine pens, but many of the others suffered from diseased legs and feet. White Cochins were such a class as is seldom seen; and so good was the first-prize pen that the silver cup for the best Cochins or Brahmas was awarded it. The second and third-prize pens were little inferior in point of merit. The *Cochin* chickens were numerous, and the first-prize pen was especially noteworthy.

There was a good master of *Brahmas*, and the competition was very close. The whole class was commended.

Golden-pencilled *Hamburghs* were good, as were also the Spangled of both colours; but among the Silver-pencilled were birds sadly out of condition, though the cup for the best pen of *Hamburghs* was awarded in this class to Mr. Beldon's birds.

The Variety class contained *Polands*, *Creve-Coeurs*, and *Houdans*. In Game *Bantams* the prizewinners were of great beauty, and the class large. A neat little pen of Black took the first prize, a pen of miniature Cochins was second, and a pretty pen of Gold-laced third.

In *Ducks* Aylesburys were poor and very badly shown in most cases; but the Rouen were much better, and the Ducks in the Variety class exceedingly fine.

In the following Game classes many of the apparently best birds proved defective on handling, both in respect to softness, want of condition and crookedness of breast; and many had Duck claws, though in other respects good.

In single cocks two silver cups were awarded, and two money prizes; the first prize going to a Black Red, and the second and third positions were secured by two very good Brown Reds shown by Mr. Robinson.

In the class devoted to local exhibitors a cup was given by the Hon. Secretary, and the competition was very close; in fact, so good were the birds, that they would have stood well in the general classes. Of Game chickens there were birds as good as could be desired, and the cup was carried off by Mr. Fletcher's Black-breasted Reds. One of the best birds in the Show was, perhaps, the single Game Bantam cockerel which won the first honours. Some very good Game pullets were shown in pairs, the first and second-prize birds being especially fine. We gave the awards in our last week's number.

ESKDALE POULTRY SHOW.

THE arrangements at this Show, of which we published the prize list last week, were excellent. The entries were scarcely so numerous as last year, owing to the fact that three other Shows, Ulverston, Aberdeen, and Paisley, were held on the same days; however, the deficiency in numbers was more than counterbalanced by the superior quality of the birds shown.

The single *Duckling* cock class, considering the prize of a silver cup, we thought a very moderate lot, with the exception of the first-prize bird of Miss Malcolm. The *Game* cock prize of a silver cup was competed for by a capital lot of birds, chiefly from the neighbourhood. The first-prize bird was a splendid Black Red belonging to Mr. Hardie, good alike in hand, style, and feather; the second and third prizes went respectively to Brown and Black Reds, scarcely equal in form to the first bird. The Silver-Grey *Dorkings* were a very fine collection, the first-prize birds being very noticeable for their size and trueness to colour. The Dark Grey *Dorkings*, old and young, were a good lot, especially the first-prize chickens. The adult *Spanish* class was good, the first-prize birds of Mr. Paterson were a fine pair; and in chickens, the first prize cockerel was decidedly one of the best that has ever been exhibited in that part of Scotland; the pair was immediately claimed for £5. In the old *Game* cock and hen class there was a fair collection, Black Reds taking the first prize; and in chickens Black Reds were again in the front, a very fine pen being first; Brown Reds were second; and in Any other variety of Game, good Piles were first, and Duckwings of fair quality second. In the *Cochin-China* and *Brahma Pootras* classes there was a small show, but among them were several good lots. *Hamburghs* appear to be the breed at present most cultivated in Scotland. The first-prize Silver-pencilled, first-prize Golden-pencilled, first prize Silver-spangled, and first-prize Golden-spangled, were birds of great merit. In the Variety class, good *Creve-Coeurs* were first, and capital silver *Polands* second. *Game Bantams* mustered strongly; the first-prize Black Reds were a fine pen, and the first-prize Duckwings were also very stylish and good. *Turkeys* were a fine lot and of great weight. *Geese* were large, and beautiful in both shape and colour. In *Ducks*,

the Aylesburys were a fine collection, especially the first-prize birds: the Rouens were large, and of good colour, Mr. Hardie again taking first and second prizes. Of other varieties of Ducks there was a good show. In the cottagers' class the birds would have done credit to any show; in fact, many of the birds would have competed successfully in the general classes, there being scarcely an indifferent pen in the lot. *Pigeons* mustered strongly, and some of the specimens were of great merit, conspicuous being the first-prize Nuns, Almonds, Kites, Turbats and Fantails.

PAISLEY ORNITHOLOGICAL ASSOCIATION'S SHOW.

IN regard to the quality of the specimens which competed, this was the most successful Exhibition that this Association has yet held.

Of the 394 pens of poultry, *Spanish* occupied forty-five. A great number of the old birds were rather over-faced, but the young class showed plain and pure faces and lobes. Mr. McInnes's second pen was universally admired. Coloured *Dorkings* have greatly improved in weight. The young Silver-Grey cock of Mr. Alston was a beautiful bird. In *Cochin-Chinos*, Mr. Stewart was again successful with Buifs, but was hard pressed with the Countess of Eglington's Whites. There was a great improvement in the *Brahma Pootras*, especially in the colour and markings of the hens. The old *Scotch Breed* was well represented in twenty pens. The *Hamburghs* as usual came out in large numbers; seventy-three pens were occupied by them. The Silver specimens were better than at previous Shows. The first Pencilled cock of Dr. Colligan was much admired. The *Polish* fowls were extra good. In the forty-three pens of *Game*, some fine specimens were shown by Mr. Alexander and Mr. McNab. Mr. Menzies' Duckwing cock was very superior. The *Game Bantams* occupied thirty pens. The Brown Reds were perfect in colour. Black Bantams were not so numerous, thirteen pens competed, but the quality far surpassed what is customary in this quarter.

The *Pigeon* department numbered 123 pens. In Pouters, Mr. Sharp's Blacks, and Mr. Sutton's Blues were good. Fantails and Jacobins were well represented. The Nuns, although not numerous, were good.

The *Canary* department was all that could be desired. The entries here were more numerous, but the specimens were never so good.

The names of the Judges, and a list of their awards appeared last week.

DUMFRIES AND MAXWELLTOWN ORNITHOLOGICAL SOCIETY'S SHOW.

LAST year pens were provided for the large fowls; on this occasion pens were also procured for Bantams and Pigeons. The arrangements of the Show were most excellent, and were admirably carried out by the indefatigable Secretary, Mr. John Maxwell, aided by a very efficient Committee.

This flourishing Society has already done much good in stimulating the breeding of poultry of a superior quality. Each successive year shows an improvement in the character of the poultry exhibited.

The entries were 385, as last year; scarcely any pens were empty. The Show, for the superior quality of the poultry exhibited, was the best ever seen in Dumfries.

Game fowls headed the list. The Black Reds, &c., were very superior. The first-prize cock belonging to Mr. J. Harding, Maxwelltown, is a very handsome bird—he was also first at Dalbeattie Show. The young birds in the class were not so good as the older, but the first and second prize pens were excellent. Of Duckwings and Whites there was a capital show. Mr. Thomas Maxwell taking both first and second prizes with two pens of fine fowls. In the Young class the first prize and silver medal were gained by Mr. John Brough, Carlisle.

In *Spanish* fowls, Miss Nelson took both first and second prizes, and the silver medal in the Any age class. In the class for young birds, Mr. John Kerr was first with a superior pen.

The *Dorkings* were the pride of the poultry department, being nearly all of a high character. The first prize and silver medal in the Any age class went to Mr. Arundell, and a capital pen from Mr. W. Lyons, Kilmichael House, was second. The class hatched in 1867 was excellent, the first pen, belonging to Mr. Thomas Ferguson, being very good; and the second, from Heathat Hill, closely rivaling them.

Only four pens of *Cochin-China* fowls of any age were shown, but the whole were remarkably good. Lady Jane Johnstone Douglas gained the first prize with a pen of white birds, of Bras House blood. Mr. Moffat gained the second prize, and was highly commended, for two pens of the same strain of blood. Of young birds there was a good show—the best pen being from Lady Jane J. Douglas, Lockiebie House. There were some good birds among the *Brahma Pootras*.

The Aylesbury Ducks, though few, were very good—the birds being large and of handsome shape. Those from Lockiebie House were first-rate, and the second-prize pen from Kilmichael House were nearly equal in merit. Rouen Ducks were more numerous, and most of the pens contained very choice birds. Mr. Thomas Parker gained the first prize. The Bantams were very good.

The entries of *Pigeons* were numerous, and there were many very beautiful birds in all the classes.

The competition in *Cage Birds* was first-rate, Mr. James Thorpe gaining seven of the first prizes for Canaries.

We gave a list of the awards last week.

POUTERS AT CALNE.

Nor having seen Mr. Heath's Pouters for two years, and knowing that he had greatly increased his stud during that time, I paid him a visit recently. I was fortunate in having a bright, sunshiny, mild winter's day, which the birds enjoy, and upon which they show up well; also, I arrived when all the stock was at home, and before Mr. Heath had sold off a number, which he does annually before the breeding season.

I was prepared to see fine birds, as not only Mr. Heath bought some of the stock of the late Mr. Bult, but he has risen in the fancy, frequently taking prizes at the largest shows. Nor was I in the least disappointed, but exceedingly gratified.

A house for Pouters should be set differently from that for any other Pigeons. It is best on the ground floor, with lofty and roomy pens, in front of which the fancier can walk, his pets being thus easy of access for taming and caressing. Hence, a loft above a stable or coach house is unsuitable, as in such a man often cannot stand upright, and the Pigeons' nests are on the floor. Mr. Heath has made an excellent house for his birds by advancing a building from the south side of a high wall. The pens are arranged chiefly with their backs to the wall. The floor of the house is well boarded, and all very clean; there is plenty of air and light, and every ray of sun is admitted. A large sash window is in the centre of the front, which in the daytime is opened, and the birds come out into a square wired court, in the middle of which is a fountain, the basin being kept the right depth for the Pouters to wash; and a pretty sight it is to see the elegant birds wading about, splashing, drinking, and enjoying themselves.

I found Mr. Heath particularly strong in White Pouters. They are long fine-shaped birds, of apparently great constitutional vigour. He has also Red Pies, Black Pies, Yellow Pies, and Meales. Even those not long enough to secure a prize would be famous birds for a beginner, or one keeping Pigeons only for amusement. Mr. Heath has invented a machine for measuring Pouters, which is a great improvement upon the old plan of stretching them along the front of a pen.

After spending much time in examining the birds, I fed them, and it was a beautiful sight to see the floor covered with well-bred Pouters of good contrasting plumage. The feeders were mingled with them, and, I own, did take off a little from the beauty of the scene, but when it is possible, I incline to the plan of hand-feeding.

The stock of Mr. Heath is well worth seeing, and I might travel many miles before I saw one equal to it. May he long prosper, and may his careful and judicious management of that noble variety of Pigeon, to which he is devoted, bring him all the success he desires. And I hope his example (and that of a spirited fancier is always contagious), may stir up others to cultivate that finest and most striking of all Pigeons—the English Pouter.—WILTSHIRE RECTOR.

PIGEONS.

At the request of several of our principal Pigeon fanciers in Glasgow and in Edinburgh, I have been induced to examine the merits of the book entitled "Pigeons: their Structure, Habits, and Varieties." By W. B. Tegetmeier.

When first advertised I looked forward to its publication with no small interest, the breeding, rearing, and study of "domestic Pigeons" having been my principal pastime from boyhood. Having read all the old works on "fancy Pigeons," all the books I could lay hands on pointing in any degree to that subject, and knowing that these books were open to all inquirers, I felt hopeful that Mr. Tegetmeier would offer to the present generation something new, if not important, founded on his own experience; that now the long-felt want was to be supplied—a work so composed as to excite the interest of general readers, to unfold fully the beauties and peculiarities of that handsome class of birds, and thus aid in creating a love for them, and possibly swelling the ranks of our fanciers and breeders.

In the first part of this book we have an account of the structure and general character of Pigeons, and, in connection with that, a quotation from the Duke of Argyll's "Reign of Law,"

and Chapter I. closes with a needless quotation from John Hunter, and a page of remarks on the Doves indigenous to Great Britain.

Chapter II. consists of two quotations: one from Macgillivray, and the other from Henry D. Graham, on the Rock Dove.

In the Introduction to this book a very interesting statement is promised us—something really new to me—viz., "The evidence which proves all our varieties to have been derived from one and the same wild species." This statement Mr. Tegetmeier is to consider. The so-called evidence occupies twelve pages. Ten of these pages are quotations from Darwin, Huxley, &c. (and Mr. Tegetmeier here introduces himself very ingeniously as "a great authority"). This so-called evidence—the mere opinions of two or three scientific men (all of which we have read before), amounts to nothing as far as *proof* is concerned. The most guarded, and, I think, sensible writer on this subject, quoted in the pages referred to, seems to be Professor Huxley. He says, "I daresay there may be some among you who may be Pigeon fanciers, and I wish you to understand that in approaching the subject, I would speak with all humility and hesitation, as, I regret to say, that I am not a Pigeon fancier. I know it is a great art and mystery, and a thing upon which a man must not speak lightly."

Mr. Tegetmeier, however, shows a bolder front than the learned professor does on this subject, and among the few remarks he makes we have the following:—"Some Indian fanciers in distant ages (for Pigeons have been kept as domestic pets many hundreds of years in India), observing that certain Pigeons were produced with extra feathers in the tails, mated them together, and again selecting those of the offspring that showed the desired characters, succeeded eventually in creating the Fantail." (The ancient Indians referred to seem to have had nothing to do with the "creating" of the tremulous motion in the neck of this bird). I do not know whether Mr. Tegetmeier intends to offer this as a fact, or merely as his own idea; but really it reads like some baby story, such as we have heard in the nursery, beginning with "Once upon a time, long, long ago," &c. However, I speak with reserve; Mr. Tegetmeier may have the advantage of me. It is possible he has in his possession, or may have obtained a sight of some unpublished manuscript of our old friend Baron Munchausen; if so, I give up this point. No one can find fault with, or for a moment doubt the correctness of the information Mr. Tegetmeier gives us regarding his own paternal parent: what he was, and where he lived; but when he attempts to father all the beautiful varieties of our domestic Pigeons on the small Blue Rock Pigeon, it comes to be quite another question. There is no intention, nor is this the place or time to argue this subject; but at a future period I hope to be able to enter fully into it.

Part III. of this book, with the exception of two pages, is on the "Pouter." The principal portion of it is made up of quotations, and of the few remarks made by the compiler, some of them had better have been left out. I refer more particularly to the matching of colours. Mr. Tegetmeier recommends matching a "Black Pied with a Mealy." If this be done the consequence would be, in the produce, a sooty or blue black, showing the bars on the wing. Then a "Red Pied and Mealy, but with some risk to the bright red." Of course in the produce the fine colour would not only be destroyed, but the bar would also appear. Then "Yellow Pied may be matched with Mealy with advantage." The produce would be mostly Mealy Yellows, with strongly-defined bars. If yellow, pale in colour—lemon, in fact, showing the bar. And again, worst of all, "Blues may be matched with Reds." Here, again, would the colour be destroyed, and the bar introduced where it would be most objectionable. Lastly "Blue Pied and White are not a desirable match, as very white pied birds, or white-splashed, or speckled with other colours would most probably result." This last is a most desirable match; it will sometimes produce perfectly marked Blue Pied, and at other times perfect Whites; but if splashed or speckled with other colours they will prove the finest stock birds for both Blue Pied and Whites that can be had. See the Pouters bred in Scotland. But I fear Mr. Tegetmeier does not know the colour in Pigeons termed "Mealy," as no one who understood colours would advise such combinations.

The compiler talks of the "slavish fear of breeding away from some one particular colour," and refers to "the late Mr. Bult," an ardent fancier, "who rejected this practice" of confining himself to one particular colour in matching, or even

to separate breeds; "and it was to his freedom of action that his great success was mainly to be attributed." I knew Mr. Bult well, and as well do I remember when he destroyed his stock of Pouters by crossing them with a Mottled Runt, and finding it hopeless to support his position as a fancier and breeder of Pouters by the produce of this unfortunate cross, he applied for and received birds from his friends in Scotland, which were the origin of his "celebrated strain." The cross-bred Mottled birds were runtish to the last. The chapter on the Pouter is lengthened-out by accounts of two sales of Pigeons by auction, of not the slightest interest.

In Part IV. we have the Carrier and Dragon; nothing new, principally quotations, and then follow twenty pages, five of them running into the following part, on "Homing Birds," or, in other words, Mongrels, bred for flying, shooting matches, or the table. I fear these twenty pages will be lost to those whom they most concern, as the class who keep this sort of bird can, as a general rule, seldom afford, and are as little inclined to pay the sum of 8s. for any book. Mr. Tegetmeier's "experience of the habits and management of these Homing birds dates from a distant day" he says; and this class of birds seem to have been his "fancy," which in a great measure accounts for his want of knowledge of the distinct breeds from their origin downwards.

We have in Parts V., VI., VII., and VIII. the Tumbler, Barb, Fantail, Trumpeter, &c., an array of quotations, many of them useless, and, according to the compiler's own showing, absurd. The only original remark in those parts, which I feel constrained to notice, appears in page 152, in connection with the Fantail. The compiler writes, "The author of 'The Dovecote and Aviary,' in his facile and pleasant manner, plays, as usual, round about his subject, without giving us any new or even accurate information respecting it." I confess I do not understand the purport of this paragraph. If nothing "new or accurate," why give us a full page quoted from this author? Why, would the last part without it appear too thin? I do not personally know either the compiler of "Pigeons," or the author of "The Dovecote and Aviary;" but certainly the latter is an "author," and one of no small merit; and although I cannot agree with him in all his ideas and remarks, still his work alluded to is written in an original and popular style, and its pages tell us that the author is one who writes from subjects studied by himself.

This book closes with the "Laws relating to Pigeons," and "The Diseases of Pigeons." The former is not worth the time occupied in reading it, while the latter leads me to the conclusion that Mr. Tegetmeier has never kept a Pigeon worth attempting to cure; if so, he gives us none of his experience, does not say when or how he succeeded or failed, or even if he tried. He tells us, "If birds are kept in localities where they are permitted to fly at large, housed in well-sheltered lofts, having a sufficient supply of wholesome food, clean water, &c., . . . that disease will be almost if not entirely unknown among them." I have fourteen pairs of Blue Antwerps, kept for feeders, flying at large in a fine airy locality outside this city; they are well sheltered in a large clean loft, and have the best of everything. Almost daily, sometimes two or three times a-day, they will take a flight of from three to six miles at a stretch. During this past year I have had four cases of wing disease among them, one of fallen gizzard, four of roup; and three young Pouters being fed by some of them, died of purging. Mr. Tegetmeier talks of "scrofula" among Pigeons, and of its being "hereditary." No such disease ever attacks Pigeons, nor is there one that is "hereditary;" not one disease to which they are liable is even infectious. "Roup," the most likely of all to be infectious, is not so, as any fancier of experience must have discovered long ago. As for the prescriptions for the diseases, what does Mr. Tegetmeier recommend? "Copaiba balsam" and "nitrate of silver," ancient prescriptions, indeed. I have tried them twenty-five years ago, and found them to be worse than useless—the best drugs for irritating the diseases and killing the birds.

Mr. Tegetmeier is evidently a disciple of Darwin, and professes to adopt the theory of that author, as far at least as the present subject is concerned; but although aspiring to scientific attainments, he does not attempt to give us any experience of his own in support of this theory, or any reason why he should insist, as he does, upon those who may read his quotations adopting it also. This style may suit Mr. Tegetmeier's purpose, and that of all copyists and compilers—those who write from what others have written, but who have not taken their observations from the subject itself; but I feel convinced

that neither the theory, which is so constantly introduced, nor this book-making, can be acceptable to the intelligent and educated Pigeon fanciers of the present day.

No one can write on this subject satisfactorily, even to himself, however scientific he may be, unless he be a "Pigeon fancier" and one of practical experience; and Mr. Tegetmeier shows himself throughout this book, to say the least of it, ignorant of the subject he has taken in hand.

The volume is, with the exception of a few pages, composed of quotations (Mr. Tegetmeier actually quotes *himself* more than once); and although void of anything new, I find on the covers of the last two parts he is advertised as "author of 'Pigeons.'"

The coloured illustrations, as a whole, are a failure; some of them are certainly near the mark, and I rather think the original outline of others may have been destroyed by the "printing in colours." The Pouter is the best; but no one ever saw a Pouter blowing in the position represented—standing on one foot. If the bird is meant to be represented as walking, the raised foot is much too high; otherwise it is well drawn and beautifully printed. The Almond Tumbler is the worst. The woodcuts, with some exceptions, are truthfully drawn and spiritedly engraved. The principal exceptions are the front and back views of the Fantail. The former looks like an apoplectic chicken issuing from a lady's muff, and the latter reminds us of something like the footprint of an unshod horse, both being monstrous caricatures of that graceful little bird. The artist, like the writer, must be a practical Pigeon fancier, to do his work perfectly in this very peculiar department, for without doubt it is "a great art and mystery."—JAMES HUIE, *Rowan Cottage, Crosshill, Glasgow.*

CANARIES.

ALLOW me correct an error that has crept into your report of the Sunderland Ornithological Association's Show. Instead of £5 in money, Mr. Ashton won £11 10s. in money, and also sold two Goldfinch mules for £20. This is almost the highest price, if not quite, ever paid for Canaries at shows. I mention the fact to show that the interesting study of breeding Canaries and mules is, I am glad to say, on the increase. Why cannot we have a standard of excellence and a Canary club just as poultry fanciers have theirs? I am quite willing to work if somebody will help me. We could have a large exhibition every year at some of the principal towns in England, and show the public generally that Canary-breeding is as pleasant and instructive a study as breeding Pelargoniums or bees; and when properly carried out, and good specimens bred, as profitable, if not more so. I will subscribe £20 towards a club, and work willingly if, as I said before, anybody will help me.—HENRY BEDWELL, *Polefield Hall, Prestwich, Manchester.*

DOINGS IN A SMALL APIARY IN 1867.

(Concluded from page 38.)

In connection with driving, I may mention a singular circumstance which happened to two of my stocks. On the 13th of July the morning was fine, sunny, and rather calm. About two o'clock in the afternoon clouds gathered in the west, and distant thunder was heard. Between 4 and 5 p.m. a heavy thunderstorm came on. The bees, acting on their instinct, returned to their hives in vast numbers some little time before the storm broke in force, and only a bee occasionally could be seen at the entrance. At this period I had left the garden and sought shelter. During the storm I observed a stream of bees suddenly issuing from a hive which I had casually cast my eye on, as I passed the window. My curiosity being excited, I looked at a second hive just within sight; there, too, the like occurrence was taking place. At each of the alighting boards cluster after cluster gathered and fell to the ground. The poor bees were actually being driven out of their hives by the heavy rain beating incessantly on the sides and roof of the casing. After the storm abated, I went and inspected the hives, and found them about as effectually deserted as though I had operated on them with a view to that end. There was a large cluster of bees under the bottom board, also a mass of bees on the ground, many of which were buried from the heavy splash. By night, most had betaken themselves to their hives, and the following day all went on much as usual.

In 1866 I asked the question, if common coarse brown sugar

would answer for feeding driven bees. Its not being affirmed that it would do so, I had resolved to try it myself. Out of nine driven lots of bees on the 31st of July I kept three, and designate them thus: D, beat-outs (two joined, 5 lbs. weight), placed in an octagon, straw, bar-and-frame (3), hive, home-made, and inducted at the same time as driven; and E, beat-outs (single, 2½ lbs.) placed in a 13-inch square box hive with bars and frames. To feed these, I purchased a quantity of the cheapest coarse brown sugar I could procure, made it into syrup, and commenced feeding therewith from the top of the hives, keeping the supply constant. This was readily taken by the bees, and in fifteen days D's hive was nearly combed, and a little food stored. E had six combs about halfway down, also a little stored. The weather being warm and open, and the scent from the syrup being strong, wasps were very troublesome.

I discontinued feeding for three weeks, when I again began with the same kind of food, but now I could not in any way induce the bees to take it. Day after day a few bees might be seen at the full feeder, apparently indifferent; store the food they would not. I tried adding honey to it, but with no better success, and after a week's further trial I was still no nearer my object of inducing them to store their combs, so I gave up the attempt, and tried the best brown sugar. This they at once began to store; also to extend their combs. They would store any amount—in fact, the two hives have been made up to weight with this. They have a fair share of sealed comb. I weighed them on the 4th of December, and found that each had consumed 2½ lbs. from the 17th of October. To establish each hive of bees cost 8s. 6d. They are healthy, and, I believe, will be found all right in the spring.

From this trial it would appear that the coarser sugar will not answer, except for the first week or two of comb-building. The combs are remarkably white. Personally I should object to its use, as from the very strong scent emitted wasps are exceedingly troublesome to the bees; besides which, bees from other hives attempt to rob, causing fighting and restlessness at hives.

A few further notes relative to the driven single lots of bees of the autumn of 1866 may not be without interest (for their previous history see vol. xi., page 399). From the time of driving, each hive of bees was rapidly fed up to weight. They wintered well, and became active and strong. Of the two given away, one threw a swarm on the 11th of last June, and a cast on the 23rd. From the other a swarm issued on June 16th, and from some cause returned; but on the 1st of July it threw off a very large swarm, which was retained by myself, and distinguished as C. At its head there was a fine and prolific queen. This did not swarm; it became, and still is, very strong, and had the season been favourable would, I have little doubt, have given a handsome super: even as it was, it gathered more than either of my old stocks. I now dismiss them, merely expressing confidence in the experiment, and assure other beekeepers who may desire to try the like, that they need have no fear of the result.

The year 1867 leaves me with six hives of bees, one being Italian, and I think all are in favourable condition.—J. G. C., South Northamptonshire.

HONEY HARVEST OF 1867.

REPORTS of the honey season of 1867 from different parts of the kingdom have now appeared in the Journal, but, so far as I have observed, not one has been sent in from Dumfriesshire.

Here, as in Edinburgh, the bees came through the winter splendidly, being injuriously affected neither by the severe frosts of January nor the mild open weather of February. On the 15th of the latter month pollen-gathering commenced, and when March arrived the apiary was full of promise; but from that time forward the weather became cold and ungenial, and during the early part of June the most flourishing hives were found to be retrograding, and would soon have perished from their stores becoming exhausted, had not a favourable change taken place on the 17th.

The last week of June and first thirteen days of July were all that the apiarian could desire, and the bees were not slow in taking advantage of the opportunity offered of collecting from such flowers as could be found. Had the white clover been as abundant as in former years, the yield of honey would have been large, but it was both late in making its appearance, and very scant when it did appear. The fine weather had

departed ere its full blossom was shed, and to this cause must be ascribed the deficiency of the honey harvest in the locality where I reside. However, with glasses well filled, one of which weighed 25 lbs., and stocks sufficiently stored to carry them through autumn and winter, I have not much room for complaint. There were also a few fine days in August, during which considerable progress was made in honey-gathering.

Though the season, therefore, has not been equal to many others, it can bear most favourable comparison with 1853, 1854, and 1862, when the collection of honey was nil.

The same thermometer, in the same situation, which this year indicated 70° for upwards of several days, never rose above 58° during June and July in 1862, and I had not a single swarm. With Mr. Lowe I regard a "swarm on the wing" as one of the most beautiful sights that the eye can behold.

There is this year, in my immediate neighbourhood, a peculiarity in the character of the honey from which I am happily exempt—viz., it is dark, treacly, and insipid, and so offensive to the eye as to repel many from eating it. The aphides bear the blame, and perhaps they deserve it.

December, now closed, has been a very trying month to bees, owing to the sudden and frequent changes of temperature. The 10th proved a most destructive day. It was fine and mild till about 2 p.m. The hives felt the influence, and sent out their inmates in myriads; but an unexpected cold set in. Bees on the wing were chilled before they could return to their homes, and they perished in vast numbers. I was from home at the time, but on the following day I collected about three thousand immediately in front of the hives, and succeeded, by the application of a little heat, in recovering a good many. The constitutions of resuscitated bees that have been subjected to any lengthened exposure are, however, always to some extent undermined, if not destroyed.

In common with those readers of the Journal who welcome it for the apiarian page alone, I perused with much interest the account given of the Egyptians' doings in Edinburgh. The short interval between first and second swarms, and the vast numbers of young queens reared to supply the place of the old one, are features quite new in our past experience.

No one has yet responded to Mr. Woodbury's request for suggestions as to how humble bees might be conveyed to Australia. I have found their queens during winter hibernating in a mound of garden earth, apparently without any protection save what the earth afforded.

Might not mould, mixed with moss, be put into a small jar, and the jar be deposited within a Syrian water cooler, and be thus made to answer the purpose of an ice room?

I throw out the suggestion, which may be worth nothing, in the hope that others will follow.—R. S.

OUR LETTER BOX.

WING OF BROWN RED GAME COCK (*An Inquirer*).—A dark russet brown bar is the proper colour on the wing of a Brown Red Game cock, and not black. There is often a green bar across the middle of the wing, but not always. The lower end of the wing should be of a dusky, dark, smoky brown, and not black. A Brown Red cock should show no black at all, except in the tail, legs, nails, beak, and eyes; and should "cut out" very dark, with dark fluff at the root of the tail.—NEWMARKET.

TURKEYS AT THE HANLEY SHOW (*A Looker-on*).—We are not acquainted with the weight of the birds. You seem to overlook the fact that great weight is not the only qualification for success. Birds in best condition at Manchester might be not in high condition at Hanley.

GROUND OATS (*Dunelm*).—Write to Mr. Agate, Slough Mills, near Crawley, Sussex.

EGG TESTERS (*C. L.*).—We have no faith in them. We certainly would not place eggs a month old under a hen if we could have others more fresh. We do not mean that some of them would not produce chickens; but, as a rule, eggs not more than a fortnight old produce the strongest chickens.

MANGOLD WURTZEL FOR FOWLS (*W. Golding*).—If boiled it is a very good addition to their food.

MANDARIN AND CAROLINA DUCKS (*S. D.*).—They would not succeed in a space 6 feet square.

CHEAP EFFICIENT HIVE—LIGURIANS (*New Subscriber*).—Try Payne's Improved Cottage Hive, described in page 5 of "Bee-keeping for the Many," but of a rather larger size, say 16 inches diameter by 9 inches deep, and adopt the sterilizing system in place of the collateral. Write to Mr. Woodbury, Mount Radford, Exeter, for information regarding Ligurians. You will find in "The Gardener's Almanack" for the present year, published at this office, price 1s., or free by post for fourteen stamps, a bee calendar from Mr. Woodbury's pen, which is pronounced by competent authority to be the most complete.

WEEKLY CALENDAR.

Day of Month	Day of Week	JANUARY 23—29, 1868.	Average Temperature near London.			Rain in last 40 years.	Sun Rises.		Sun Sets.		Moon Rises.		Moon Sets.		Moon's Age.	Clock before Sun.	Day of Year

From observations taken near London during the last forty-one years, the average day temperature of the week is 44.8; and its night temperature 31.7. The greatest heat was 57°, on the 29th, 1863; and the lowest cold 5°, on the 28th, 1865. The greatest fall of rain was 0.90 inch.

ALTERATIONS IN SMALL FLOWER GARDENS.

LOWER gardeners as a rule have an appetite for new plants which is not easily satisfied, and often adopt some which have very little except novelty to recommend them; yet as regards the arrangement of colours in beds or borders, and the disposition of walks, clumps, standards, vases, and all those little features which contribute to form that harmonious whole which we call a flower garden, many even of the very best are just as apt to fall into conventional grooves, and follow year after year the same old beaten track, as our grandfathers were, whose standstill policy in these matters is now often commented upon.

A sociable old farmer has a laughable story or a good joke. He has told it over and over again, until half the county and the whole of his acquaintance know it as well as he does himself, so that it has long since lost all the raciness it ever had; yet to the humorous teller it somehow seems to be ever-green, and his whole fabric continues to be shaken with healthy laughter every time he retails it. So also it often happens with a clever young gardener; he has laid out a small flower garden, most likely from a design of his own. It is a decided success, and is acknowledged as such by all who see it. Then many an hour is spent in planning how it shall be planted, and in considering the heights and colours of the plants to be used, and the greatest number it will be possible for him to rear. After much pleasant labour and anxiety, it is filled, and in summer, when the colours have begun to produce their effect, the arrangement is found to be also a great success; people of taste, on whose judgment he can depend, say it could scarcely have been better, and he takes them at their word. It is a good story, and is repeated one season after another with only trifling variations, until we might almost imagine the plants to be well-drilled soldiers, falling into their proper places of their own accord. Now this constant repetition of anything, however beautiful, must in time weary the eye of taste; every line and curve, this blue bed edged with white, that scarlet one in which there never was anything but Pelargoniums, and these Humeas, have all grown so familiar to those for whose gratification they are there, that were the whole swept away, and the plan destroyed, a fac-simile could be produced by them with little or no difficulty. The gardener, too, if not unduly biassed by a natural prepossession in favour of his own production, may, perhaps, begin to feel just a little tired of looking at these stereotyped copies of his beautiful picture, but will most likely attribute it to the fact of their being all but constantly under his eye.

Now, though the breaking through an old and well-considered programme is often followed by consequences more troublesome than most people imagine, yet, in order to make and keep small flower gardens interesting to some, frequent changes are absolutely necessary; for, while more extensive grounds and parterres are, by the varied phases

they present from different points, and by their very breadth and massiveness, always attractive, yet with patches of perhaps a fraction of an acre this is not the case, and radical alterations every year or two, not only in the style of planting, but in the arrangement of the beds and walks, if possible, will be found very much more efficient for this purpose than any substitute of new for old bedding plants.

Where this cannot be done, the introduction of a few vases, of pieces of terra cotta, balustrades so placed that they can be half-covered with low Roses, a little ornamental wire trellising, or a few specimen shrubs where there were none before, will have a wonderful effect, and few means will be found more useful for transforming these miniature landscapes than a good stock of hardy shrubs grown in pots. All the attention they require is not very much, and they can be moved about at any season with the greatest ease, and sunk in the ground where wanted to suit any new arrangement. Those suitable for this purpose are so numerous that every one, instead of consulting lists, should rather be guided by his own taste. Rhododendrons, Portugal Laurels, Aucubas, Laurustinus, Berberis Darwinii, Thujas, Yews, and many of the finer Conifers may be used, and the culture and management of a considerable number of these as pot plants have often been treated of in the pages of this Journal.

In visiting the villa gardens round London, nothing strikes the wondering country gardener more than the great profusion of what are by courtesy called rockeries, it being rare indeed to find a garden without one or more of these curious creations, often in the most conspicuous places. They are not, nor are they, I believe, meant to be, imitations of anything grand in nature, and though custom may have made them attractive, yet to a stranger they appear anything but ornamental. I have often wondered if the busy city gentleman did not see enough of bricks and rubbish throughout the day, without having a cartload or two tilted up in his well-kept suburban garden on which to refresh his eyes in the evening. It is decidedly a mistake attempting rockwork at all on a small scale, and it is little less than an outrage to place it where there are no corresponding features, but where everything around is in the highest degree artificial; so that in laying out a small flower garden anew no provision should be made for it.

There are circumstances, however, under which these frequent changes are not desirable, and where they exist the gardener should always respect them as far as possible. I refer to that mysterious yet very real faculty, possessed more or less by every mind, of making the most prominent features with which we happen to be surrounded so many connecting links between the present and the past; where every tree, and shrub, and bed is a hieroglyphic laden with meaning to those who can read them—mementoes of lost friends, or objects around which are thickly clustered the recollections of many happy years, and which when removed or obliterated leave a painful blank which no new attractions can fill. And though the discussion of this part of the subject scarcely comes within the gardener's province, yet where these ties may be expected to exist

they should always be taken into consideration when planning improvements or alterations, and at all times tacitly respected.—**AYRSHIRE GARDENER.**

SUCCESSFUL ORCHARD-HOUSE CULTURE.

ABOUT four years ago the thought occurred to me how much I should like to erect an orchard house; so, after having made myself thoroughly acquainted with Mr. Rivers's little book on this particular subject, I consulted the advertisement pages of the Journal, and soon found the very thing I believed would suit me—namely, a tree cover, manufactured at Birmingham. After a correspondence with the firm that advertised, I had a length of 40 feet 6 inches erected against a south wall in my fruit garden, in Wiltshire. It was finished on Christmas eve, 1864, and so pleased was I with it, that I immediately applied to the same firm for 40 feet more; but on receiving a reply that what they had done for me was merely an experiment (a most happy one for me), and that they could not add more except at a very considerable advance in price, I wrote to a respectable firm in Bath, who contracted to add what I required at much less cost, and I have now an elegant structure 80 feet long, 9 feet high, and 8 feet wide, with ample ventilation at the top and bottom. And now for the results.

Fruit trees had been previously planted in the border against the wall, and the consequence was a good crop of Peaches and Nectarines, and also of Strawberries in pots, the first season. The second year I had a very fair crop of fruit, and the last season, 1867, more than seven hundred Peaches and Nectarines of exquisite flavour, besides a large quantity of Plums and Cherries grown in pots, and a few well-ripened Apricots.

I should also state that twelve choice Vines were planted at 64 feet apart, with the view of securing a partial shade, the thermometer during the last two summers having frequently ranged from 95° to 100°. From these Vines I have cut fifty-five bunches of well-ripened Grapes, most of them well coloured, some of the bunches of the Alicante weighing just 2 lbs., and grown without any artificial heat.

The thought often occurred to me, How is it I so frequently read of failures in orchard-house culture? Surely there must be some cause why fruit should not succeed under glass, and I have come to the conclusion that it is this: Either the master does not understand the management of the structure, or the gardener may, perhaps, think that he has quite enough to do without the additional work which an orchard house is sure to entail if properly attended to. I have the good fortune to have an old and confidential gardener, who has lived in the family for nearly half a century, and takes and feels as much interest in his work as if all under his care were his own property. I gave him Mr. Rivers's little book, with this remark, "Do not attempt to fill your head with too much at a time, but read a little, and follow the directions as nearly as possible, and I think we shall succeed;" and he has done this to my entire satisfaction, as the trees, after a heavy crop, are all looking most promising and full of blossom-buds for this year.

The border where the tree cover stands had plenty of trenching mould put into it when first made; and as the space is limited we frequently top-dress with rich manure, as the roots are always seeking nourishment from the surface. All the trees in pots are top-dressed twice every season with malt dust and sheep manure, and manure water of some sort is always used twice a-week. The Vines have likewise bones and charcoal; but two most essential points to insure success are free ventilation, and plenty of water which has been warmed by the sun's rays. All the plants are syringed before sunrise and after sunset.

Mr. Rivers, as well as Mr. Pearson, and others, have given some valuable receipts for smoking orchard houses, but I can assert that mine has never required this treatment, nor has it ever been done. We have found it an excellent plan to have the wall and fruit trees whitewashed during the winter, and early in the spring to have all the plants and Vines done over with a solution of lime, soft soap, soot, and sulphur, the latter being freely used in a dry state, and placed about the border in tins. It keeps the house thoroughly healthy, and it is an effectual preventive of the depredations of wasps, &c., as they do not like its fumes when the sun is shining; but it is removed just at the time the trees are in blossom, or my special friends the bees would decline to pay their always-welcome visit.

We have for some time given up using shreds, as on examining them I have frequently found a deposit of the eggs of

insects, &c., using as a substitute small hooked nails, and tying the shoots to them with matting.

I was often much amused, when first commencing, by some persons telling me, "You may grow Grapes if you like, but you are sure to find it an utter failure with other fruit trees; the leaves will all blister and curl up, and you will have no fruit"—more than a slight mistake most assuredly, as it has been often remarked by my friends that they never saw a better crop, or trees in finer condition, and as regards the flavour of the fruit, all have said who have tasted, Give me a Peach or a Nectarine grown under glass.

I can never mention Mr. Rivers's name without a feeling of gratitude for the immense amount of pleasure and gratification I have derived through him and his writings. May his shadow never grow less, and his substance ever increase.—**BATH.**

CUPRESSUS MACROCARPA.

It is to be regretted that this beautiful and fast-growing tree should be liable to the mishaps described by Mr. Kent and "A SOMERSETSHIRE PARSON," but I fear their complaints of its shortcomings will be too generally confirmed to leave much hope of its attaining the dimensions of a large tree. Still, we ought not altogether to despair of such a result. The fact of its doing well on a very stiff clay, as stated by "A SOMERSETSHIRE PARSON," is well worth knowing, especially as those having so obstinate a soil to deal with are not always acquainted with the ornamental trees which there thrive, although they may know what common trees succeed. I, as one, therefore, thank him for his communication, and beg to offer some further remarks on this handsome tree.

In the autumn of 1852 a small plant of this Conifer was sent here in a pot, and as it was reported to be not hardy, it was kept in a pot the whole of the following year. It was not until May, 1854, that it was planted out, but it had been out of doors a great part of the time, though sheltered in severe weather. In planting it out, the roots were carefully disentangled, and extended at their full length before being covered up; even one or two of the largest roots which would not give way were fractured rather than they should remain coiled close to the collar. Fortunately the plant had several roots all springing from its base, and did not consist of one or two large roots with all the others proceeding from them, as I have seen in other specimens, and which is much to their disadvantage. It is to this circumstance that I attribute in a great measure the after-success. Planting, I need hardly remark, checked growth much. Part of the season was spent ere the plant recovered, and in the following spring, that of 1855, it was about 24 feet high. Its progress then and afterwards was most rapid, for some years in succession averaging 3 feet annually; and last autumn it was 36 feet high, the growth in the past season having been less than in any previous year, owing to the plant having suffered so much from the frost of the previous winter.

Surrounding the tree there are specimens as high as itself of *Picea cephalonica*, Cedar of Lebanon, and Spruce Firs, which have, no doubt, had the effect of sheltering it from high winds, but whether they will be of service when this fine tree overtops them, time alone will determine. So far it has withstood our highest winds without further damage than a slight inclination towards the north-east, our highest winds coming from the opposite direction, but younger trees have succumbed to the gale. We all know that very high winds find out even sheltered places. An old friend of mine, a forester of long experience, used to remark that in general more trees are blown down in valleys and sheltered places than on hill tops, and I believe he was right.

The sheltered position of the tree no doubt preserved it in a great measure, and its hardiness appeared to be equal to that of the Scotch Fir and Cedar of Lebanon up to January, 1867. Indeed, I may say until May, for, unlike many other species of Conifers and shrubs, no token of injury appeared till in that month the foliage on all the lower branches and for a considerable distance up the tree became discoloured, and much of it fell off; the growth being in consequence more feeble. The foliage now, though still existing on the tips of most if not all the branches, is so thin that the interior dead twigs and naked stems can be seen all around. This was not the case before, for on walking round the tree no twig thicker than the finger could be seen without putting the branches aside, so dense was the foliage, and so long did it hang. The top of the tree was

scarcely affected, the damage being, as I have stated, chiefly lower down; but I have no doubt the partial injury to the top checked the energies of the plant, and the summer growth was therefore less than usual.

In comparing the hardness of this plant with that of others, it is difficult to arrive at anything approaching a definite conclusion. A *Pinus insignis* between 50 and 60 feet high and nearly 40 feet in diameter was scarcely in the least injured, although only 50 yards or so from it; while another specimen of the same species, about 40 feet high, and almost touching the *Cupressus*, was nearly killed, every leaf exhibiting that reddish brown colour so common last May, but it promises in a year or two to recover. Some other specimens of 30 feet in height or less were but slightly affected, and several smaller plants of *C. macrocarpa* in another place did not appear to have suffered at all. A plant of *Cupressus Udeana*, about 15 feet high, situated near the tall *Cupressus*, was completely killed, being almost the only specimen of any considerable size with which this was the case. *Thuja Lobbi*, 25 feet high, was not in the least injured; and *Thujopsis borealis*, 14 feet high, was almost improved by the cold.

I think "A SOMERSETSHIRE PARSON," or any one whose soil is of a very stiff clayey nature, might plant *Taxodium sempervirens*, which I have growing freely by the side of a piece of ornamental water in soil as stiff as can well be imagined, and it did not suffer more than a larger specimen growing near the *Cupressus macrocarpa*, in a moderately dry stony soil. I am, therefore, inclined to think, that if *Taxodium sempervirens* be not actually benefited by moisture, it will endure it. The effects, however, of the frost of January, 1867, appear in many instances so different in different cases, that we ought not to arrive at conclusions too hastily. Only a short distance from here, on a gentleman's lawn which is accompanied with a piece of ornamental water and a waterfall, a fine healthy *Aranea* growing within 10 feet of the water's edge, and the turf at its collar absolutely lower than the water level, passed through the winter without injury, while *Taxodium sempervirens* and *Cryptomeria japonica* only a short way from it, but both higher in the ground and farther from the edge of the water, were much injured. The *Aranea* was growing close to the waterfall, and if any water did escape through the cemented embankment, it would quickly be drained into the stream below. The tree looked remarkably well, although near it an Evergreen Oak, thirty or more years old, was all but killed. The effects of the frost of January, 1867, were so capricious that it would almost appear as if some cold wave had settled irregularly on certain places, altitude not being always the law regulating the degree of cold.

I should be glad to hear favourable accounts of the hardness of *Cupressus macrocarpa*, which I would place in a list of the best twenty Conifers known, and before last year I would even have included it in a smaller list. The past twelvemonth, however, has proved that in addition to its liability to be blown down by high winds, its hardness is questionable. This is unfortunate, as few plants of any kind present such a dense lively green; and in point of symmetry, quickness of growth, and other features, it seems indispensable where speedy effect is required. The fact of the tree having attained the height which it has done here, coupled with that of its not having been in the least injured by the winter of 1860-61, will, I hope, with the corroboration of other parties, weigh sufficiently in its favour to cause its being retained in the list of ornamental trees suitable for all places in the south of England, and for all but the most exposed situations in the north of England and in Scotland. The eccentricities, if I may call them so, of last winter's frosts may not be repeated for many years, and those places that were then so severely affected may escape next time. For my own part I fear danger to this plant more from wind than cold; and I imagine the misfortune Mr. Kent records has had many parallels, for, in a sailor's phrase, a plant carrying so much sail is in constant danger of being laid on its side. A careful bracing at the bottom at planting time is the only means of preventing such accidents, and even that does not always succeed.—J. ROBSON.

I HAVE read with interest the articles on the hardness of *Cupressus macrocarpa*, but my experience tells a different tale.

We had here four fine specimens varying from 18 to 24 feet high, and from 12 to 15 feet in diameter, which were entirely killed by last winter's frost. Not a green branch was left to tell us of the beauty that had perished, or to give the faintest hope of recovery; and the axe and saw had to be employed to

lay low what a few months before had added much beauty to the place. The situation is high, and the soil of a light peaty texture.

A neighbour had eighteen fine plants varying from 12 to 26 feet high. We had the misfortune to lose seventeen; but the eighteenth, being in a warm situation, escaped.

One of our plants was within 10 yards of a fine plant of *Aranea imbricata*, which withstood the frost, and is now doing well.

I think I have said enough to show that *C. macrocarpa* is not hardy enough to stand such winters as that of 1867 in all situations.—E. CHITTY, *Outlands Park, Walton-on-Thames*.

THE JOSÉPHINE DE MALINES PEAR.

THERE is a peculiarity in the tree of this charming and excellent Pear which cannot be too widely known—viz., its perfect and enduring health when grafted on the Whitethorn (*Crataegus oxyacantha*); so that any one possessing a good Whitethorn hedge may grow abundance of this valuable late Pear by selecting some clean stems and grafting them, so that the heads of the trees are clear of the hedge.

A tree now growing in a hedge on a hill of gravel close to the town of Hertford is now some fifteen or more years old, and it seldom fails to give some pecks of fine clean fruit, equal and sometimes superior to those from trees on Pear or Quince stocks. My attention was very recently drawn to some trees of this kind grafted on the Whitethorn, and growing in a stiff clay. To my surprise, I found the junction of the graft with the stock scarcely to be distinguished, so perfect is the union. The trees are remarkably clean and healthy, and bear very fine fruit. Unlike some kinds of Pears when grafted on this stock, the cores of my Whitethorn Joséphines are not hard, neither is their flesh gritty, but nearly always perfectly melting, and of a rich perfumed flavour. I have had thirty years' experience of this most distinct variety, and no winter Pear has varied so little in its character, and no late Pear in my opinion more deserves extensive culture. Every farmer with a healthy "quick hedge," as a Whitethorn is called in Essex, should train up some stems and graft them with Joséphines, and every industrious cottager should do the same. I fear it will not ripen well north of the Trent, but there are large districts in the warmer parts of England where it may be made a valuable product.

The only kind of Pear that succeeds well on the Whitethorn for a long term of years is the *Passe Colmar*, of which I know a tree some twenty-five years old; but this sort does not as a rule ripen well, although it bears abundantly. Joséphine de Malines is of the same race. Last season (1866), my fruit of this sort were in perfection all through March and April, 1867. This season they ripened towards the end of December. Such is the subtle influence of climate on the ripening of fruit, about which we as yet know so little.—T. R.

GLASS VERSUS BRICK WALLS.

A FEW weeks since Mr. Robson, in his article on garden walls, stated that 1000 square feet of wall would produce more fruit—say Peaches, than 1000 square feet under glass.

This assertion induced me to look into the question. On referring to Thompson's "Gardener's Assistant," I observe that he states twenty dozen of fruit from a wall Peach tree of a mature age are as many as a tree ought to ripen, although that number is often exceeded by injudicious cultivation to the great injury of the tree. We thus have a basis as to the produce of a wall tree, say seven years old, and in full bearing. A wall 10 feet high and 100 feet in length (1000 square feet), will give training space for five Peach trees, which will in the course of seven or eight years cover the face of the wall; and they will, or ought, in good seasons to give a hundred dozen of fruit.

We must now look at the 1000 square feet covered with glass. This space will give abundance of room for sixty fine Peach trees in 15-inch pots; at the age of seven or eight years these trees will each produce five dozen of fruit, giving an aggregate of three hundred dozen. On a wall protection from spring frosts would be required, and pruning and nailing in winter and summer. Against this work must be placed the watering and care required by the trees under glass. A 14-inch wall 10 feet high and 100 feet in length, would cost some £30

or £40 in excess of 1000 square feet covered with glass. Brick walls to enclose gardens are necessities, I have no wish to enter into that part of the question; it is the assertion of Mr. Robson that has caught my attention. It is, I think, worthy of some little consideration by cultivators of fruit.—INQUIRER.

THE ROYAL HORTICULTURAL SOCIETY'S SCHEDULES OF PRIZES.

I AM glad to see at last a plea put forward for more encouragement to amateur exhibitors at the Royal Horticultural Society's Shows.

The Council, composed as it is of amateur horticulturists, with an admixture of noblemen and gentlemen, representatives of the great body of the Fellows, cannot be suspected of a bias in favour of nurserymen; but it is very possible, notwithstanding, that amateur horticulturists may not receive their fair share of encouragement. The Council may, for instance, be of opinion that a greater number of plants will not be exhibited with a schedule such as "F. R. H. S." wishes; and those best acquainted with the art of making shows, including Mr. Eyles, believe that the richest exhibitions are procured by the system of large classes. Still, procuring effective shows ought not to be the only object to be aimed at in the exhibitions of a horticultural society; and it is most desirable to bring out the "greater amount and variety of talent and skill" which "F. R. H. S." believes will be the results of smaller classes.

It would, however, be interesting to know what professional horticulturists think of these schedules and of "F. R. H. S.'s" views, and especially what they think of the schedule for the Rose Show. In this amateur influence has, doubtless, had more weight than in the other schedules. It is always advisable to hear both sides of a question, and though I am not one of those who desire to be constantly meddling with the arrangements of those whom we have selected to manage our affairs, I submit that the Council would do well to invite discussion on this question, and thus either assure themselves that they have nothing more to learn in schedule-making, or else ascertain and correct their errors. In every society matters are apt to fall into a groove; and the arrangement of the schedules has, probably, fallen into the hands of one or two men who may, perhaps, have crotchets of their own, or who may not be advised for the best. I suggest, therefore, that the Council name one of the Tuesday Meetings, after the London season is over, for the free discussion of their schedules for the present year. We shall most of us be perfectly satisfied with the decision they arrive at when we are sure that they have all the requisite data for forming an opinion.—INDAGATOR.

MISTLETOE.

IN 1866 and 1867 I made a journey in the fowl districts of France, in order to study the varieties, &c., and was particularly struck with the exuberant growth of Mistletoe at Hondan (Seine-et-Oise), and at Le Mans and La Flèche (Sarthe). The trees at the roadside in these districts were literally covered with Mistletoe, and I was surprised that the parasitic growth in no way appeared to check the vitality of the trees.—H. L. F. C.

I HAVE seen it in its glory in the neighbourhood of Weobley, and other places in Herefordshire. Some of the finest specimens I ever saw were on some Poplar trees in the above locality, and at 15 or 20 yards from the ground. These could be seen miles from the place. In that neighbourhood I have seen the Mistletoe on Apples, Crabs, Thorns, Poplars, Limes, and I am not certain whether I did not see some on Willows, along with *Polypodium vulgare*.

With regard to finding it in the northern counties, it may be met with in the neighbourhood of Nappleton, a few miles from York. Not long ago I saw it at a place called Ormesby, among the far-famed Cleveland hills. Near the mouth of the Tees, a few miles from Redcar, I saw it growing in an orchard.—M. H., *Acklam Hall*.

SALVIA ON THE COL DE TENDA.—In your last impression, page 46, you ask if any of your readers recognise the *Salvia* your correspondent "D. S." saw on the southern slope of the

Col de Tenda. It is in all probability *Salvia violacea*, commonly called Purple-topped Clary; it grows here, and seeds itself very freely, also *rubra*, the Red-topped—two very old annuals rarely met with at the present time.—W. GRIFFITHS, *Guy's Cliffe, Warwick*.

A SIMPLE WAY OF GROWING EARLY RHUBARB, AND A QUESTION ON POTATOES.

I AM a poor man fond of gardening, and try to improve my knowledge by practical experience on a few hundred yards of garden ground. I was desirous of having a little early Rhubarb this year of my own growing. I tried one of Shirley Hibberd's plans two years ago, but failed; so this year, or rather in the first week of December last year, I took the bottom half of a broken earthenware bowl, 18 inches in diameter, and a cast-away "set pan" about the same size, and planted in each a large old Rhubarb root, shut them up closely in a recess near the kitchen fire on the oven side, and watered as required. I have to-day fourteen stalks of nice pink Rhubarb, and I am likely to have a great many more soon. Some of the stalks are 14 inches long, exclusive of leaf. As this is better than I expected, I thought many other poor readers of your Journal ought to know how to grow cheaply this delicate vegetable at this season.

And now, will any one of your numerous readers be good enough to give through your columns the names of one or two varieties of White Round and the same of White Kidney Potatoes that are really handsome, fit for any show table, and prolific as well? In trade catalogues almost every Potato has some remarkable quality ascribed to it, as a reason why it in particular should be bought, and as I cannot afford to test and try every kind, I am anxious to know which is best from those who have sought and found the above desirable qualities. In the beginning of last year I planted some Early Oxford (Soden's), and the few that grew to a size suitable to show—some two or three at a root, the rest, though very numerous, were only fit for pigs—were beautiful, and were awarded the first prize at a good show; but as I do not keep pigs, but have a family of children, I want to know of some more equally-tubered variety.—YORKSHIRE.

[We recommend you to grow the following Potatoes:—Coldstream Early, Daintree's Early, Lapstone Kidney, and Royal Kidney.]

WHAT IS A CORDON?

WHEN you made the statement "that M. Du Breuil introduced the word *cordon* to express certain modes of training which we have called 'the spur system,' in contradistinction to the laying-in system of pruning," I wrote to you in the interest of truth. I quoted the same author to show why he introduced the forms that go by that name, and how the word came to be so much used amongst French fruit-growers. I gave his own language, and indicated precisely where to find the passage, so as to guard against all possibility of mistake. You reply by stating that I have "most unfairly" quoted him; that I well know M. Du Breuil does not say what anybody who refers to his book can readily see that he does say; and that I have quoted just enough to "suit my own purpose." These are hard words, and if I deserved them I should be unworthy of an inch of space in your paper. I have the greatest contempt for anybody who misquotes an author for any "purpose," and if you do not acknowledge the injustice of your remarks on this point I shall be more surprised than I was at your statement of Jan. 2nd that, "cordon, therefore, does not mean any particular form of trained tree." (1) With this note the work from which you say I have quoted so unfairly shall be left at your office, with the passage marked in which M. Du Breuil says distinctly what you deny.

The clearest proof of what I assert is afforded at p. 323 of the latest edition (1868), of the author for whose definitions and labours you have such high and just respect. There he deliberately divides the various forms into two groups—one the large forms, such as the *palmettes*, *crantails* (fan-shaped), and *candelabres*, the other the "little forms or cordons." It is needless excess to state and to repeat, as you have done, that he "uses the word *cordon* generically and not specifically." As there are vertical cordons, oblique cordons, spiral cordons, horizontal cordons, and various other kinds of cordons, he must of necessity use the term generically. If your definition

be correct, M. Du Breuil would use the term *cordon* to express the spurred-in branches of any fruit tree. He does nothing of the kind, but uses the term *branch* just as we do, as I could prove to you from many passages in his works. Can you point out any proof in his book that he invented the term to express what we called "spurring-in?" The definition that you have given of the term is most certainly an exceptional one, as may be seen from the highest as well as lowest French authorities. In the instance which you give is it not stated that the tree is a *palmette* as regards the form? In that case the term is used in its exceptional sense; and in the new and excellent edition of Du Breuil which I now leave with you the name *cordon* does not occur in connection with the large and compound forms. The simple truth is, that the French would no more think of calling a tree *en cordon* because it had spurred-in branches than we should think of calling a revenue cutter a frigate because both vessels happened to be built of the same kind of wood! The term was used long before Du Breuil's day, and especially in connection with the Vine trained after a horizontal fashion, as expressed by M. Carrière, of the value of whose definition in connection with the present use of the term your readers may judge by his defining it as "every part of a plant trained a little horizontally," whereas many of M. Du Breuil's cordons are perfectly vertical, and perhaps the most popular form of all for walls is the oblique cordon.

With regard to the gratuitous footnote in your last, in which you offer me the meaning of the word *courson*, I have merely to remark that our correspondence has afforded me several opportunities of forcibly indulging in that kind of "reasoning" if I admired it, and to add that the *cordon* Peach trees in hundreds of French gardens have their side branches long and every one laid in! Does not this alone prove the value of your definition? As accuracy is desirable in speaking of such matters, I may add that this may be seen under glass in a long Peach house in M. Rose Charmeux's garden at Thomery, and in the open air in Baron Rothschild's fruit garden at Ferrières.

—ONE OF THE DISPUTANTS.

[We take the earliest opportunity of withdrawing the charge we made in our last against our correspondent of having unfairly quoted from M. Du Breuil's book just as much as suited his purpose. Our correspondent has sent us the last edition of the book, dated 1868, and there we find his quotation complete and perfectly correct. Our quotation, equally correct, was taken from the edition of 1860, and the edition of 1868 we had not then seen. The application, then, of the term *cordon*, so far as M. Du Breuil is concerned, resolves itself into an appeal "from Philip drunk to Philip sober." What M. Du Breuil considered a *cordon* in 1844, 1850, and 1860, he considers something else in 1868; for there is no shadow of doubt that, in this last edition of his book, he confines the application of it entirely to those simplest forms of trees consisting of a mere stem with spurs or *coursons*, and no ramifications on them, and the various kinds of which our correspondent so accurately describes in his present communication. What then is to be done? Are we to abandon the idea we have held for the last quarter of a century, and which was obtained from Lepère and Du Breuil, and follow the latter in his new nomenclature, or are we to hold fast by the old? For ourselves we shall adhere to the old until we see M. Du Breuil himself more decided in his application of the term than he even now is; for in this very edition he represents a tree, on page 346, with two parallel diagonal cordons, which on page 345 he calls an oblique *double cordon* tree. Then at page 480 (*fig. 336*), in the illustration of his *cordon oblique simple*, he introduces a tree with a perpendicular stem and *four* cordons upon it. If, then, M. Du Breuil can so accommodate his meaning of the word as to make it applicable to a tree of a single, a double, or even a greater number of cordons, then we decline to accept his last definition of a *cordon*, and fall back upon that much more rational and comprehensible one of M. Lepère and M. Carrière, which is that cordons are the secondary branches pruned close, and of which there may be as many on a tree as suits the convenience or taste of the cultivator.

In admitting the *double cordon* figured on page 346 as a *cordon* tree, we are at a loss to conceive by what process of reasoning can M. Du Breuil or his disciples refuse to admit a triple cordon also in that class. And if he cannot reject the triple cordon, how can he limit the number of cordons a tree shall bear to exclude it from being classed as a *cordon* tree?

But there is no reason why we should confine ourselves to the French idea of what should constitute a *cordon* tree. The word itself is good English, from a Welsh root, *corden* being

the term in that aboriginal language having the signification of a rope or string; and as there seems so indefinite an idea as to what constitutes a French *cordon* tree, let us have a nomenclature of our own, based on the rational principle that a *cordon* being a continuous simple branch issuing directly from the stem, and close-pruned, trees trained on that principle can be distinguished in specific terms by which each form may be known. In our present number Mr. T. F. Rivers has made a very successful essay on the subject, and one which may be accepted as sufficient for the purpose of fixing a *cordon* nomenclature.]

ROYAL HORTICULTURAL SOCIETY.

JANUARY 21.

FLORAL COMMITTEE.—The exhibition of plants on this occasion was limited, but some of those produced were of considerable interest. Mr. Wiggins, gardener to W. Beck, Esq., of Isleworth, received a special certificate for a numerous and most beautiful collection of Cyclamens, the strong robust plants composing which, though little more than fourteen months old from the seed, that having been sown on the 14th of November, 1866, were profusely covered with large and fine flowers. Mr. Wiggins is well known as a very successful cultivator and exhibitor of Cyclamens, and fine as these were, we may expect yet finer from him in the course of the spring. Some particulars as to his system of managing this highly ornamental plant were given in our pages in a notice of one of the exhibitions in the early part of last year. A special certificate was also awarded to Mr. Wiggins for a collection of Chinese Primulas of a very fine strain. They were in beautiful bloom, and some of the flowers measured fully 2 inches in diameter.

From Mr. Salter, Versailles Nursery, Hammersmith, came a collection of cut blooms of the new Japanese Chrysanthemums, which have already been more than once noticed as exhibiting a variety of curious forms, and which are likely to prove very useful for conservatory decoration, especially as they will yet continue in bloom for six weeks. In colour the blooms sent were white, yellow, bronze, and lilac. A special certificate was awarded for the collection. A similar award was made to Messrs. F. & A. Smith for a collection of Tricolored Pelargoniums. Mr. Wills, Huntrope Park Gardens, also sent a small basket of Beauty of Calderdale, which though good for this season, was not in a condition to show its full beauty. It was accompanied by the following note:—"My object in sending the plants up at this early season is to show the value of the Bronze and Gold Zonal Pelargoniums for conservatory decoration during the winter months. The plants sent will show how well they keep their colour during the dull season of the year. For the last three months they have had scarcely three hours' sunshine on them. Some large plants I have of Beauty of Ribblesdale, Beauty of Calderdale, Perilla, Model, Her Majesty, and many others have been flowering very freely all through the winter; the flowers they produce are of fine shape and substance, and the trusses large and of fine outline. When we take into consideration the beauty of the foliage and the richness of the flower as well, and their adaptability for winter decoration, I think it will be admitted by all that they are a most valuable class of plants, suitable alike for bedding-out purposes in the summer, and for conservatory decoration in summer or winter. Even the winter storehouse may be made to assume a very gay and neat appearance by judiciously intermixing the Silver Tricolor and light and dark green Zonal Pelargoniums with these beautiful varieties. I have no doubt the Bronze and Gold Pelargoniums will be very extensively used for all of the above-named purposes as soon as they become more generally known."

Mr. Green, gardener to W. Wilson Saunders, Esq., received a special certificate for a small but very interesting collection of rare plants, including Monacanthus Henchmanni, from Bahia, with very singularly-shaped greenish yellow flowers; Goodyera discolor, with seven very ornamental spikes of flower; Oncidium abortivum, a botanical curiosity; Colubaria trichroma, figured and described in the "Botanical Magazine" of the present month, by no means a new plant, however, though rarely seen; likewise a very ornamental Adiantum from Brazil, and Anthurium species from Bahia, with glossy leaves 9 inches in length by 6 in width at the broadest part, and of which the foliage is even more ornamental in a younger state, having then a copper hue. Messrs. Backhouse, of York, had a special certificate for a small collection of Orchids, consisting of Odontoglossum Hallii from the Andes of Ecuador, with richly blotched flowers; Lælia albidula, Odontoglossum nebulosum, very pretty, white spotted with brown; and the little bright-coloured O. roseum. Mr. Standish, of the Royal Nurseries, Ascot, sent two well-bloomed specimens of Lælia furfuracea; and Mr. Sherratt, gardener to J. Bateman, Esq., Knypersley, a very fine and beautifully coloured cut spike of Renschanthia coccinea; also Ipea speciosa, from Ceylon. For these a special certificate was awarded, and one was also given to Mr. Hodges, gardener to E. Wright, Esq., Gravelly Hill, Birmingham, for a small collection of cut Orchids. The same exhibitor also received a first-class certificate for Lælia anceps Dawsoni, a fine variety.

Mr. F. R. Kinghorn, Shiehn Nursery, Richmond, again sent the Japanese Juniper and Thuja, from Nagasaki, which had been shown

at the December meeting, but the Committee deferred coming to any determination respecting them for the present.

Mr. R. Weatherill, nurseryman, Finchley, sent two new varieties of *Solanum*, the result of a cross between *S. hybridum* and *S. pseudo-capsicum*, and named respectively *S. pseudo-capsicum* Weatherilli, and *S. pseudo-capsicum rigidum*. To each of these, on account of the size, abundance, and ornamental character of the fruit, a first-class certificate was awarded. The variety called *rigidum* is very compact and erect in habit. A special certificate was also awarded Mr. Weatherill for a collection of *Solanums* finely fruited.

Messrs. Backhouse also contributed several specimens of Beet with ornamental foliage, similar in colours to those shown by Mr. Salter at previous meetings.

FRUIT COMMITTEE.—G. F. Wilson, Esq., F.R.S., in the chair. Mr. Higgs, gardener to Mrs. Barchard, Putney Heath, sent a seedling Apple of more than average size, ovate shape, and of a fine golden yellow colour, prominently ribbed on the sides and round the eye. The Committee considered it a good kitchen Apple. Mr. Carter, gardener to W. Brookes, Esq., Mistley, Essex, sent an Apple he found there, and which was raised by one Adam Scott. It is of good size, roundish or cylindrical in shape, and with a brownish tinge on the side next the sun. The flesh is yellowish, tender, and with a flavour resembling that of the Blenheim Pippin. It was considered a good dessert Apple, but not superior to other varieties now in use. Mr. R. Fenn, of the Rectory, Woodstock, exhibited a dish of Cox's Orange Pippin in fine condition and of excellent colour; the flesh was tender and of good flavour. Mr. Stewart, of the gardens, Nuneham, sent fruit of Ribston Pippin, also in fine condition. These two dishes exhibited great skill in the preservation of the fruit. Mr. Fenn also sent a dish of Knight's Monarch, which were beautiful samples of that variety. Mr. Tillery, of Welbeck, sent a fine dish of Winter Nellis, the fruit being very large, and so well kept they were still not quite ripe.

Mr. Fairbairn, of the gardens, Sion House, Isleworth, exhibited two specimens of Cocoa Nut grown in the gardens of the Duke of Northumberland there. They were perfectly ripened, and one was full of milk. The Committee awarded them a special certificate, and recommended the exhibition to the Council as a proper object on which to bestow any medal they may have at their disposal. The Council determined to award Mr. Fairbairn a gold Banksian medal.

Mr. Stevens, of Trentham, sent a dish of Black Hamburgh and one of Lady Downe's Grapes, both of which were fine specimens of their varieties. Mr. Tillery, of Welbeck, sent dishes of West's St. Peter's, Trebbiano, and Alicante; and Mr. Standish sent small bunches of Royal Ascot. The bunches of Mr. Stevens were unusually fine at this season of the year; and Lady Downe's was considered superior in flavour to the Black Hamburgh, and a special certificate was awarded them. The Royal Ascot, being fresh Grapes, were not put in competition in regard of flavour, but the flavour was much fresher, and by many who were present they were considered superior to the others.

A large collection of fruits from Canada, consisting principally of Apples and Nuts, was exhibited by Mr. W. T. Goldsmith, Millmay Road, Stoke Newington. Black Gilliflower is a long dark fruit, with tender flesh, and good flavour. King of Tomkins County, a large handsome Apple, was also of superior flavour, and with a fine firm flesh. Rhode Island Greening was firm in flesh, and had fine flavour. Baldwin had tender flesh, of good flavour, but rather musty from being in contact with straw. Green Pippin was tender in the flesh, but past. Yellow Bellefleur is a very nice Apple, with a fine delicate flavour—a delicious Apple. Wagener is a fine Apple of excellent flavour, and with a peculiar aroma. *Æsopus Spitzenberg* was also fine. Of *Pomme d'Api* the fruit was small, and not remarkable for flavour. Grantham Sweet was not remarkable for flavour. Twenty-ounce was tender-fleshed, but not of much flavour, being already passed. Norton's Melon is a good firm-fleshed Apple, but with not a great deal of flavour. Northern Spy was so musty from being in contact with straw as to be disagreeable. The Nuts consisted of Black Walnut, Hickory Pig Nuts or Large Hickory, and Chestnuts. The Committee awarded a special certificate. Mr. Goldsmith also exhibited tins of preserved Peaches and preserved Tomatoes, and a bottle of Tomato jam. The Tomatoes and Peaches were very fresh and excellent, and the Tomato jam was most delicious. A special certificate was also awarded to the jam. Mr. Pottle, of Little Bealings, exhibited his patent Cucumber box, which the Committee considered was useless. A box of very fine fruit of the Guava was received from Mr. Taplin, of Chatsworth; but it came too late for the meeting.

GENERAL MEETING.—G. F. Wilson, Esq., F.R.S., in the chair. The meeting was purely of a formal character. Eight new Fellows were elected, and the proceedings closed with the Chairman's announcing that the Annual General Meeting would be held February 11th, at 3 P.M.

SOLANUM CAPSICASTRUM.

THIS is one of the most useful plants for conservatory decoration during the winter season, especially plants of it the second or third year from seed. I planted-out some one-year-old plants last May; they flowered and set fruit freely. I took them up in October, potted them, kept them in a close pit till they commenced rooting freely, and they are about 8 inches

high, with about a hundred berries well coloured, making them perfect gems for table decoration.

Visiting Mr. Weatherill's nursery a few days ago, my attention was drawn to a *Solanum*, a cross between *hybridum* and *capsicastrum*, in habit a little like *hybridum*, but much superior, being darker in the foliage; consequently the contrast between the berries and the leaves is much more distinct. The berries, too, are much larger than those of *hybridum*, and much higher-coloured.—T. N.

NOTES AND GLEANINGS.

WE are informed that the following changes in the Council of the Royal Horticultural Society will be submitted to the General Meeting of Fellows on the 11th of February:—Lord Sandon, Mr. W. W. Buller, and the Rev. Joshua Dix retire, and their places are to be filled by Mr. J. Russell Reeves, Mr. W. Marshall, and Mr. John Clutton. That these gentlemen will be generally acceptable to the Fellows there can hardly be a doubt; the names of Mr. Reeves, and of his father the late Mr. John Reeves, have been so early and so intimately associated with the Horticultural Society and with horticulture, that no more fitting person could occupy a place on the Council. Holding a high position of influence in the East, to one or other of them our gardens are indebted for some of the earliest and best introductions from China. Among these are the *Wistaria sinensis*, the Chinese Primrose, and numerous kinds of Camellias, Tree Peonies, Chinese Azaleas, Chrysanthemums, &c.; and all these were procured at a time when the country was sealed against Europeans. As a successful cultivator of Orchids, and a liberal patron of gardening, Mr. Marshall comes with a fitting qualification; and Mr. Clutton's well-known business habits and shrewd counsel, qualify him to reoccupy the position he a few years ago resigned.

MANY of our readers will be pleased to hear that Mr. Rose, who, we announced, had been appointed to succeed Mr. Ingram at the Royal Gardens Frogmore and Windsor, is Mr. Hector Rose, gardener to his Grace the Duke of Roxburgh, at Floors Castle, N.B. Mr. Rose was previously under Mr. William Thomson, at Dalkeith Park, where he so distinguished himself in the position of foreman, as to justify Mr. Thomson in recommending him to Floors. That this recommendation was merited is now fully proved by the appointment which has recently been made.

CHARCOAL FOR HAY'S STOVE.

LIKE many of your correspondents, I have been disappointed in not being able to procure peat charcoal, and so last spring I was induced to try common charcoal, and was much gratified to find that it answered even better than peat charcoal, giving out more heat. Its price is, I believe, a little above that of the peat. I have, however, recently purchased some from a charcoal burner living at Datchworth, near Welwyn, Herts; his price is from 1s. to 1s. 3d. per bushel, according to the quantity ordered. I regret I cannot give his name, but I should suppose there are not many professors of the grimy occupation in the small village I have named, and so perhaps this address—"The Charcoal Burner, Datchworth, near Welwyn, Herts," may find him.—T. R.

OTIORHYNCHUS VASTATOR.

CURTIS, in his work on the insects injurious to the farm, says this beetle cannot fly. It seems so contrary to what we might expect, to find a beetle with elytra fully formed without the power of flight, that I felt quite unable to accept the fact without investigation. Having nothing but dried specimens to examine, it appears to me that the elytra are joined together, and that there are no true wings under them. Would the Professor who so kindly answers our inquiries be good enough to let us know what we ought to find when we know how to look? There are so many persons who have suffered from the attacks of the larvæ of this and its allied beetle, the *Otiorhynchus sulcatus*, which are known to gardeners by the name of ringers, that any information will be welcome.

Many persons who have had young Vines, Rhododendrons, Azaleas, Yews, Camellias, &c., destroyed by these grubs, which remove the bark from the stem just below the ground, do not know of what insects they are the larvæ; others who have

seen the eyes eaten out of their standard Roses and young fruit trees, or who have seen the shoots and leaves of their young Vines eaten, either do not know the cause, or, if they are acquainted with the beetle, do not know it as the parent of the ringer. These are the reasons why I think a good paper on these destructive weevils would be so useful.

It appears to me that what gardeners want, is a cheap liquid to kill the grubs in the soil, without being injurious to the plants. The grubs are now in a young state in warm houses feeding on the roots or stems; later in the season they will be found out of doors. If plants could now be watered with some liquid such as I have indicated, the mischief would be prevented. As these insects particularly affect peat soil, such liquid must not contain lime, which not only destroys peat, but is injurious to most plants which grow in peat. As soon as I have an opportunity I shall try Fowler's insecticide, to see if it will kill the grubs in soil. Some time ago, as a preliminary trial, I soaked a Camellia and an Azalea by letting the pot stand in a vessel of this preparation for some minutes, and the plants appear quite uninjured; so if it will kill the grubs when surrounded by soil it may answer the purpose.

If the above few remarks direct attention to these injurious insects my object will have been gained.—J. R. PEARSON, *Chilwell*.

PROTECTING TREES FROM RABBITS.

IN your number for December 26th "MONTICOLA" is at a loss to account for rabbits, and he might have added hares, always attacking plants newly put out. Surely he himself supplies the solution when he says, "No rabbit will touch growing trees if it can find a prostrate one at which to nibble." The check to growth given by planting-out is no doubt the same in kind, though less in degree, as that which follows cutting-down. He will probably find mixing grease with gas tar for smearing the stems a good plan; it prevents the tar from cracking and peeling off. In the Duke of Sutherland's plantations at Trentham I used to see three or four small sticks dipped in tar set close round the young trees, and we have tried the same with good effect. It appears that the rabbit, like the rat, with which the Germans generally couple it, avoids soiling its fur with tar, or perhaps it dislikes the smell. By this plan all injury to the plant, by smearing its stem, is avoided.—J. P. O.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

CATTLEYA AMETHYSTOGLOSSA (Amethyst-lipped Cattleya).—*Nat. ord.*, Orchidaceæ. *Limn.*, Gynandria Monandria. Native of Brazil. Lips reddish purple, and petals and sepals spotted with the same colour on a white ground.—(*Bot. Mag.*, t. 5683.)

COTYLEDON VELUTINA (Velvety-leaved Cotyledon).—*Nat. ord.*, Crassulaceæ. *Limn.*, Decandria Pentagynia. Native of South Africa. Flowers pale green at the base with yellow above, and the limbs edged with crimson.—(*Ibid.*, t. 5684.)

VITIS PLANICAULIS (Flat-stemmed Vine).—*Nat. ord.*, Vitaceæ. *Limn.*, Tetrandria Monogynia. Native of the Sikkim Himalaya.—(*Ibid.*, t. 5685.)

COBURGIA TRICOLORA (Tricolored Coburgia).—*Nat. ord.*, Amaryllidaceæ. *Limn.*, Hexandria Monogynia. Native of the rocks of the Peruvian Andes. Flowers scarlet outside, pink inside, and limbs of corolla purple.—(*Ibid.*, t. 5686.)

OPHELIA ALATA (Winged Ophelia), *O. ANGUSTIFOLIA* (Narrow-leaved O.), *O. PANICULATA* (Panicled O.).—*Nat. ord.*, Gentianaceæ. *Limn.*, Pentandria Monogynia. Natives of the colder regions of the Himalaya. *O. alata* has greenish yellow flowers spotted with purple. *O. angustifolia*, flowers purple spotted with blue; and *O. paniculata*, flowers white with semilunar purple band in the middle of each lobe.—(*Ibid.*, t. 5687.)

BEGONIAS Veitchii and *rosaeflora*.—Both these species are, it will be observed, dwarf herbaceous plants; and even if it should prove that, whilst enduring the cold, they require some slight protection against the vicissitudes of our variable climate, we must welcome them as amongst the most valuable and important of recent acquisitions, since they are not only remarkable for the size and beauty of their blossoms, but also for the facility with which they may be cultivated. Both are natives of the Andes of Peru, and grow at an elevation of from 12,000 to 12,500 feet.

"Though presenting a certain amount of similarity in their

aspect, the two sorts are abundantly different both as to foliage and flowers. *B. Veitchii* has thick concave leaves of an obliquely ovate or roundish cordate outline, two-flowered scapes 8 to 10 inches high, and large flowers of a bright cinnabar red colour, one being female and rather smaller than the male. *B. rosaeflora* has also thick concave leaves; but they are of a more rounded outline, with much deeper basal lobes, and the veins are so deeply impressed as to render the surface bullate; while the scapes, which are red, like the petioles, are three-flowered; and the large flowers are of a clear rose colour, one of the three being female. They are thus abundantly distinct as decorative plants, and out of bloom have more the aspect of some broad-leaved Saxifrage, such as *S. ciliata*, than that with which we have hitherto been familiar amongst Begonias."—(*Florist and Pomologist*, 1868.)

FRONTIGNAN GRAPES.

I RECOMMEND Mr. Tillery (see page 2), to add Primavis [Early White Frontignan], to his other Grapes, which succeed perfectly well without fire heat. I also grew this year with it the Early Smyrna. The last is the most musky and the best of the race that I have tasted. The former is musky, the largest in berry of the race, and very good. I have added three more of each, and also one each of Foster's White Seedling, Early Golden, Early Silver, and Chasselas Musqué de Sillery. The first two and last three are Frontignans. I believe Foster's White Seedling is a Muscadine or Sweetwater. I recommend persons with orchard houses and cool vineries to buy some of these delicious Grapes. Mine were grown in 15-inch pots with a surface dressing of fresh-dropped cow dung, which they seemed to like.

My little stock of Grape Vines now consists of two Black Hamburgs, or rather Frankenthal, and the above Grapes. I will describe, if permitted, in the autumn, the Early Golden, Early Silver, and Chasselas Musqué de Sillery, for Mr. Tillery's information. Foster's White Seedling and Early Smyrna I see are in his list.—W. F. RADCLIFFE, *Okeford Fitz-paine*.

CORDON TRAINING.

THE introduction of the system of training fruit trees, called by the French cordon training, leads me to suppose that a few outlines of description may not be unacceptable. This system of training is remarkable for simplicity, and I propose to give the necessary directions in as few words as possible.

The preparation of the ground is so well understood, that it is not necessary to say much on this point. To form the oblique-cordon orchard, a trench should be dug about 2 feet wide, the first spit of soil being thrown out as if for a Celery trench; the under spit should then be broken up and left with the top soil, a good proportion of well decomposed manure must be mixed, and the ground is ready for planting. The trench should, if possible, be made about a fortnight before planting, in order that the soil may be thoroughly pulverised. If there is any deficiency of lime in the soil, it is as well to add lime rubbish or chalk. For horizontal double cordons a trench is not necessary; holes should be dug about 2 feet in diameter, and the soil mixed with good compost. The double-cordon trees should be from 12 to 15 feet apart; the horizontal single cordons 6 to 8 feet. At this moment there are at Sawbridge-worth two horizontal double-cordon Peach trees, under a ground viney, which measure 21 feet from end to end, and promise, from their remarkable vigour, to be models of cordon culture next year, every spur being full of strong fruit buds.

Fig. 1 represents a double horizontal cordon. This may be made by cutting down a dwarf maiden tree to within four or six buds of the base, the two topmost buds of which must be selected to form the cordons. The highest on the stem are the most eligible; but the operator can, of course, select the two shoots which are the most convenient for his training wire, and they should be as nearly as possible opposite. When sufficiently advanced in growth to be flexible, they should be carefully bent down and fastened to short sticks, unless the training wires are used. As the whole energies of the tree are directed into these shoots, they will make rapid growth, and as they advance fresh sticks and fresh tying will be necessary. As any lateral or upright shoots are put forth they must be stopped at four or five leaves from their bases. The first year few of these will be made, but the tree will most probably, if there is a favourable growth, be studded with fruit buds. In

November, or, indeed, any month from November to March, the tips of the main shoots should be shortened three or four buds from the ends, and unless a few lateral shoots have been

left, which should be removed, the pruning for the first year will be accomplished.

The second year each cordon, or branch, will produce many

Fig. 1.

lateral shoots, and as these are successively produced they should be pinched. The first pinching must be done when the shoot has formed five or six leaves, and, as a general rule, three leaves from the leaflets should be the stopping point. This primary shoot will form the bloom buds, and the shoot made from the terminal bud must be stopped in the same

manner as the first. During the summer many of these growths will be made, and pinching should continue until the end of August. After this month pinching should be discontinued, and the remaining growth left for the winter pruning.

The tree after the second year will assume the appearance of a cordon—*i.e.*, a thick rope of closely-studded shoots, and

Fig. 2.

the pruning must be left to the judgment of the operator. Many shoots must be removed; and as the size and strength of the tree must regulate the number of fruit-bearing spurs, a sufficient number of these being left, the operator should prune all others to wood buds, in order to produce year by year an alternate succession of fruit-bearing wood.

Fig. 2 is a half-standard double horizontal cordon. This is very useful for low walls in gardens; where the border is occupied by flowers or other plants the part of the wall exposed to the sun may thus be used. A standard cordon with a stem 6 feet high may also be used for the top of a wall, the main surface being occupied by other trees. A cordon fringe, or cornice, will be

Fig. 3.

found exceedingly ornamental, and may be carried the entire length of a wall, the standards being planted at intervals of 20 feet or more.

Many other forms of cordon training will, doubtless, be discovered as the system becomes better known.

Single horizontal cordons (*fig. 3*), require the same pruning as the double, but the dwarf maiden tree does not absolutely require the cutting-back necessary for double cordons. The tree may be planted in a slanting position, against the train-

ing wire, and the shoot tied down. The first year after planting most of the buds will break and produce shoots; these must be treated in the same manner as the double horizontal cordons. If a single cordon is required for a special height, the shoot should be shortened to the height required, and a single horizontal shoot selected to form the cordon.

Single oblique (*fig. 4*), cordons may be planted to training wires by the sides of walks, or in rows in the garden devoted to their cultivation. The space given up to them will yield an ample

and quick return in fruit. They may be planted $1\frac{1}{2}$ foot apart, and if the cultivator does not object to wait a year, dwarf maiden trees are the best to plant, as they may be bought cheaply. The trees should be planted upright, and the shoots, which are generally very flexible, should be bent to an angle of about 45° . It is not necessary for the angle to be quite acute; but, as a general rule, this angle may be adopted. If the shoots are not flexible enough to bend, plant the tree in a slanting position.

Fig. 4.

The principle of pruning given for double horizontal cordons must be followed in the cultivation of single oblique cordons. They will the first year after planting be found covered with bloom spurs. Single oblique cordons in rich and fertile soils will, probably, require root-pruning as well as spur-pruning, and, if necessary, this should be done every second year. The tree should not be taken up, but the spade pushed down at a sufficient distance from the stem to avoid injury to the main roots, and the tree gently heaved. If a tap root has been made it should be cut. The proper time to perform this operation is near the end of October, and any time afterwards to the middle or end of February; but it is better done in October and November, as many fresh shoots will be formed after the operation, even during what are called the dead months of the year.

Single oblique cordons may be carried to the height of 10 or 12 feet; in fact, there is no limit, except the will of the planter. A fresh string of wire may be added annually as the cordons increase in length. They may also be limited to the height of 4 or 5 feet.—T. FRANCIS RIVERS.

(To be continued.)

REVIEW.

The Gardeners' Year-Book, Almanack, and Directory, 1868.
By ROBERT HOGO, LL.D., F.L.S., &c.

This is the ninth year of this excellent manual, and, if possible, it improves on its predecessors. It contains the most of the general information usually supplied in almanacks—as, transfer and dividend days at the Bank, assessed taxes, regulations as to income and property tax, receipts, agreements, &c.; arrangements as to the Post Office, money orders; British and foreign monies, weights, and measures; London market fruit and vegetable measures; useful tables for wages, interest, and housekeeping purposes; also tables showing the contents in gallons of tanks whether round or square; tables for ground-work, cost of digging, trenching, excavating, according to the character of the soil; tables for sowing, planting, and the quan-

tity of plants or seeds wanted per acre; also tables for ascertaining the average weight of produce per acre; and finishing by giving rules for changing the scales of the different kinds of thermometers into each other. Fahrenheit's thermometer is the one chiefly used in this country; but as Réaumur's and the Centigrade are much used on the Continent, it is of importance to know exactly how the different thermometers stand in relation to each other.

The book, besides, has three distinguishing features: First, a list and description of new and notable fruits; a list and description of the new plants figured, described, or exhibited during the past year, the descriptions being as full as possible; and the new flowers of the year, with certificates awarded to them, embracing *Antirrhinums*; *Auriculas*, alpine and show; *Azaleas*, *Camellias*, *Carnations*, *Chrysanthemums*, *Cinerarias*, *Clematis*; *Dahlias*, fancy, bedding, show; *Fuchsias*, *Gladioli*, *Gloxinias*, *Hollyhocks*, *Hyacinths*, *Lebelias*, *Pansies*, *Pelargoniums* of all sections, occupying about eight closely printed pages, *Pentstemons*, *Phloxes*, *Roses*, *Verbenas*, &c. This part of the book seems to have been done with great care and fullness, and is to many of us a very great advantage, as we are thus enabled to see in imagination many of the beauties which we will never be able to look at or handle physically. In the first division connected with new or notable fruits, outlines are given of the Grand Duke Constantine Apple; and of *Beurré de Beugues*, *Bergamotte de Millepieds*, *Beurré de Jonghe*, *Emile d'Heyst*, *General Todleben*, and *Madame Appert Pears*.

The second feature is the garden directory. The horticultural directory used to be the grand feature of this serial; but it became impossible to compress all that was necessary to meet the wishes of nurserymen and societies in one serial, and this season it has here been confined to a garden directory, giving the names of the principal gardens, names of proprietors, names of gardeners, and the nearest post towns, in the counties of England, Scotland, and Ireland. So far as we have been able to examine, this list is more full and complete than that given last year. In the enlarged horticultural directory to be published in March, the nearest railway station to the gentleman's residence and the distance from that station will also be given; and though we have no doubt that that directory will be as cheap at 2s. as this Year-Book is at 1s., still, if this garden directory is to form a part of the Year-Book in future, we should like the railway stations and their distance from the gardens to be given, even if some things else which appear year after year were left out. We have often been sadly disappointed when, on arriving at a railway station, we found we were many miles from our destination, and no way of reaching it except walking it or hiring—and hiring is a serious affair in country places in England. In such matters Ireland beats us hollow. We have paid as much to be driven a few miles in England as we have had a car for a whole day in Ireland.

The third feature is, in this year, an excellent out-door gardening calendar for every month in the year. Last year there was no calendar. In the three years previously there was respectively a kitchen-garden calendar in 1864, a flower-garden calendar in 1865, and a fruit-garden calendar in 1866, and there were calendars in the two first issues of 1860 and 1861; but the present out-door calendar of 1868 is the fullest and best that has yet appeared. We presume that next season there will be an in-door calendar; and then there will be a few seasons without a calendar at all—a matter of no great importance to those who keep the serial as we do as a book of reference. In short, our opinion is, that the faithful description of new fruits, plants, and flowers, and the garden directory, are the features of the work; and to make either of these more efficient we would excuse the want of the calendar now and then, most excellent though the present one is.—R. F.

HOME.

WHAT myriads of associations, some painful, others joyous, cluster round this single word, for after all, "no matter when or where," "there's no place like home." To one long an exile and a sojourner in foreign lands, release from "that wasting pang, heart sickness," as good "WILTSHIRE RECTOR" expresses it, is indeed joyous. None but they who have undergone the torture can fully appreciate the blessings a lifelong residence at home conveys.

A year ago at a choral meeting in a simple Canadian church, I met an English gentleman, who had taken American orders, and was then the incumbent of an American church in the far

west, in the State of Wisconsin. He took a very prominent part in the service, and joined so heartily that he was noticed by all. At a pleasant *réunion* in the afternoon, during conversation with him, he unburdened himself, and said to me, "I begged Mr. —," mentioning our clergyman's name, "to let me take part in the service. I wanted so to pray once more for my Queen and my country—my home!" And so he did, and with a fervour unknown to those who had never experienced "heart sickness."

"WILTSHIRE RECTOR" is correct in his belief that this is no time for emigrating. Sixty thousand men are now lying idle, aye starving, in the city of New York alone, and the horror of an almost Arctic winter aggravated by want and misery, may well make one tremble at the mere contemplation. The English labourer and mechanic, although they have their trials and troubles, are far better off and happier at home than they would be in any colony or foreign land. The colonies offer but a poor field for the gardener, and the farmer finds he has again to learn everything, and in the majority of cases his experience is dearly bought. My advice is—and it is the advice of one who, to use an Americanism, "has been through the mill"—STAY AT HOME. Practice economy; but above all, cultivate a contented mind. The dreams of fortunes to be made by emigrating seldom prove realities; and many a poor heart that otherwise might now have been beating, has throbbled its last in misery, uncared-for and unknown, a stranger in a strange land.

It is true that we of the Journal fraternity have a tie which mutually binds us to each other, and which makes home seem nearer to the dweller in far-off countries; and although it is pleasant to exchange courtesies, and to stretch hands to one another across a broad ocean, yet it is pleasanter still to drop into 171, Fleet Street, as I have lately been privileged to do, and to shake hands personally with the highly esteemed Editors of "our mutual friend."

And now one word about "errant writers." "Although science and direct instruction come from other pens," who among our circle would be willing to lose "NAUD," or "WILTSHIRE RECTOR."

"All work and no play
Make Jack a dull boy."

And although we all admire and enjoy the exemplification of "The Theory and Practice of Horticulture," as set forth by the host of scientific and practical contributors to the Journal, yet would not some of its brightest pages be wanting were the "errant writers" to discontinue their favours, and much moral instruction be lost?—W. T. GOLDSMITH.

VISITS TO GARDENS PUBLIC AND PRIVATE.

MESSRS. CARTER & CO., CRYSTAL PALACE NURSERY, FOREST HILL.

It was on the day of the Crystal Palace Autumn Exhibition that, through the kindness of the Messrs. Carter, I was enabled to take a look over their grounds. September is not at any time the best month in the year for seeing gardens, still less so was it last year; but notwithstanding this, and that the firm had sent a large stand of plants to the Crystal Palace, there was abundance to recompense one for the visit. I was accompanied by Mr. Boston, the manager; and I can only say that if any visitors to the nursery could get him to tell them his own history, they would come away, as I did, heartily admiring the perseverance and determined energy which had characterised it. He could tell them of Italy under the old régime, and of the Crimean war; and I would ask no better incentive for a young man than the success which has attended him by adhering to the principle of using every fair and honest opportunity of improving his position.

It would be needless to attempt a description of the nursery, for it is similar in its outward appearance to many others near London. There are several large greenhouses, a stove, and pits, with a large space out of doors devoted to the hardening-off of bedding plants, the object being to make as much of the space and in as short a time as possible; and as the market gardener pushes on to see how many crops he can obtain from the ground, so here it is how many crops in pots can be obtained out of the houses. There is a house 130 feet long by 18 feet wide, which was filled with about 800 Vines in pots, well-ripened excellent canes of the very best kinds, a large proportion being the Black Hamburgh—after all, perhaps, the most useful Grape we have; but in the spring this house was filled with 120,000 pots of bedding plants, among them

about 10,000 plants of Mrs. Pollock. Another house, holding about 400 Vines, had formerly held about 60,000 pots (60's). The plan here is to plunge the pots in spent hops, which afford them moisture, and do not harbour vermin.

Bedding Pelargoniums, which are every year driving other bedding plants out of the field, are largely cultivated, and the race for new varieties bids fair to open out fresh fields of beauty. In this race the Messrs. Carter are not behindhand, especially in the more select class of Tricolors and Bicolors; in the former they have two sweetly pretty plants—Titania and Oberon, while Red Gauntlet is a striking plant. They have, moreover, in their Prince of Wales a plant which, if it bear out the promise it has given as a seedling, will be one of the very finest Tricolors ever raised. The leaf is very large and most vividly marked, while the habit of the plant is of the most luxuriant character. Again, in the class of Bicolors, there is one here which, the moment I saw it, struck me as being the very best of its class that I had seen. This variety is called Egyptian Queen, and is to be sent out in May. It has a bright yellow ground, with a beautifully marked bronze zone, which gives it a most striking appearance. It begins now to be felt that most probably these Bicolors will be more serviceable as bedding plants than their more refined neighbours the Tricolors. I can quite conceive what a grand display a bed of Egyptian Queen must make. It has, too, such a thickness of leaf, that it cannot fail to be, as it has been proved this summer, one that will stand weather a great deal better than most of its competitors. Another very beautiful variety is Madeleine Schiller; while Dr. Primrose, with a plain yellow leaf, is also excellent. Of course, all the best varieties of other growers are to be seen, and in large quantities; but my interest was mainly in those sorts which are peculiar to this establishment.

There is the nucleus of a good collection of Orchids here, and a plant of *Phalaenopsis amabilis* was as fine a specimen of good culture as I have seen anywhere. Here also I noticed a nice collection of a charming little plant which every one ought to have—the curious little Australian Pitcher-plant, *Cephalotus follicularis*. I say advisedly every one, for it is every one's plant. I have had a neat little specimen of it growing in my dining room for some months, and although it does not grow so fast as in a stove, yet it thrives well and looks healthy. I have it potted in sphagnum and peat, and covered with a bell-glass to exclude dust; this is tilted a little at the bottom. The plant is kept well watered, and is always an object of attraction to visitors.

Eucharis amazonica I found here treated very differently from what I had seen it anywhere else. It was grown in a cool house and allowed to dry off in winter. The plants were small, but were evidently thriving. That fine Fern *Lomaria gibba* is evidently in great request; and well it deserves to be, for this is another plant that stands well a sitting-room window, as I have a plant which has grown admirably under my wife's care, and has now attained a good size; so that here are two valuable plants for those who wish to try their hand at window gardening.

Where there is such an extensive seed business as that of the Messrs. Carter, great care is needed in the selection of seeds, that they may be good in quality and true to name. Hence the necessity of their trial ground; for they are not only obliged to have their own seed farms, but many persons throughout the country grow various seeds for them, and these must all be tested before they can be sent out. In one border I saw two thousand different kinds of flower seeds in small patches. These are subjected to two trials—first to see if the seed will germinate, and then if it be true to character. If the seeds fail in either of these respects they are at once discarded, and a supply from some other source has to be obtained. On another long border were samples of the various vegetable seeds undergoing the same sifting process. Here were rows of different kinds of Beet, there of Turnips, there again Savoy and the different varieties of the Brassica tribe. The samples are impartially drawn, and hence it is not much within the verge of probability that seeds not true to name will be sent out.

Just previous to my visit Mr. Boston had been through parts of France and Belgium searching for novelties, and had formed the same conclusion that I came to—that never were there fewer to be seen abroad than in 1867. He mentioned an *Iresine*, which I have since seen at Ghent, of a dark copper colour, that may be useful—more so than the golden-leaved variety of *I. Herbstii*, which, however pretty for the dinner table, will

never, I fear, be of any service in the garden. I saw a row of it here alternately with the ordinary type, but it did not look very attractive.—D., Deal.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Dig, ridge, and turn up all vacant ground; give plenty of air to all advancing crops in frames; clean and stir the soil among all growing crops in the open ground, and remove all decaying leaves. Keep the walks and borders in good order, and the kitchen garden clean and neat. *Asparagus*, if you have plenty of plants and command of dung and leaves you can have *Asparagus* from Christmas-day till it is cut from the open ground. *Cauliflowers*, seeds for the earliest crop may be slightly forward, together with *Radishes*, *Lettuces*, and *Potatoes*, also *Peas* and *Beans* for transplanting. *Onions*, by sowing these now on a slight hotbed, or in boxes in any house at work, much time and seed may be saved, and a surer crop may be obtained next summer, to be transplanted when fit.

FRUIT GARDEN.

Prepare the ground for those fruit trees, the planting of which could not be effected in the autumn, by thoroughly draining the borders, and forming a substratum through which the roots will not easily penetrate. In the absence of paving stones, tiles, &c., a good substitute may be formed of coarse gravel and finely sifted quicklime, in the proportion of six parts of the former to one of the latter, mixed well together with sufficient water, and laid down to the depth of 5 or 6 inches. From 15 to 18 inches of good loamy soil will be sufficient for Peach and Apricot trees; much less will do if the borders are mulched and cropping dispensed with. No manure ought to be mixed with the soil. In pruning Gooseberry and Currant bushes, care must be taken to thin these well out in the centre, so as to admit plenty of sun and air. The same remark is also applicable to standard Apple trees; the middle of the tree must be kept quite open, taking care that all the branches lead outwards, and preserve a regular distance from each other. Pear trees should also be thinned well out, and the produce will be much better in quality.

FLOWER GARDEN.

A part of this garden should in all large establishments be devoted to the rearing of evergreen shrubs, such as Laurels, Rhododendrons, Kalmias, Yews, Aucubas, and Laurustinus, which may be propagated at home, or bought in from the nursery when a year or two old at a very trifling cost. They come in very useful when making improvements, and are sure to grow from being accustomed to the soil and climate of the place. There are not many places where a few hundreds of these might not be planted with great improvement to the grounds. Auriculas may now be top-dressed, removing carefully the surface soil, and substituting some two-year-old decayed hotbed manure and leaf soil. Avoid all hot stimulating composts, for although they may increase the size of the flowers for the present season, yet they are food so uncongenial to the plant, that the foundation of future disease will most assuredly be laid. Polyanthus grown in pots may be kept moderately moist, and a similar top-dressing to that recommended for the Auricula will be of much service to them. They are, however, grown on beds with a north-east aspect with great success. A cool bottom, either artificial or natural, is necessary for their perfect cultivation. Continue to give Carnations all the air possible. If the green fly begins to be troublesome, remove it with a camel-hair brush. As spring advances the wireworm becomes more active and is mischievous to Pinks. If there is reason to suspect that any lurk in the bed, cut a Potato into quarters, inserting a skewer in each; place them in various parts, just below the soil, and examine them daily. They form effectual traps. In selecting roots of Ranunculuses for blooming, choose those with a high crown in preference to those of large size.

GREENHOUSE AND CONSERVATORY.

This is a good time to remove any Camellias that have no flower buds, to the stove, vinery, or any place where a gentle heat is kept up, and as soon as they begin to grow give plenty of water every day till their growth is finished. They may be kept in the stove till their flower buds are formed. Then, if they are kept in a cold frame all the summer, shaded for a few hours in the middle of the day while the weather is hot, and brought into the greenhouse by the end of August, they

will come into flower about the beginning of November. Another lot now in flower may be commenced to be forced a month hence for a succession. A third lot might be so treated in April, and the remainder of the stock may be kept unforced. When forced flowers are introduced into the conservatory less air should be admitted than for the collection of conservatory plants. See particularly that Orange trees, Neriums, and other plants are clear of insects before they begin growing, as young wood and foliage are very difficult to clean without injury. Most conservatory plants, being in large pots and boxes, require less water than those in smaller pots in the greenhouse. Rhododendrons and Azaleas are amongst the finest and easiest plants to force for the conservatory.

STOVE.

This is also a good time to place in a forcing pit dormant bulbs and tubers, such as many varieties of *Tippeastrum*. If these have been put to rest in their pots, it is best not to disturb their roots at present. If they want larger pots shift them when they are in full growth next month. Some of the *Gloxinias* are apt to damp-off if water lodges in the crowns of their tubers. *Gesnera elongata* is an excellent winter flower, which may be had from October to April with a little management. When this has done flowering it should be kept rather dry until it is pruned, and this should be done in succession till the end of spring. Those pruned now should flower next October. Prune the young shoots close to the main branches, and keep them in the stove with but little water till all the eyes are beginning to grow; then shake the mould from their roots, repot them in a light rich compost, and force them gently for three months. After resting in the greenhouse during the summer they should be again potted in August, or in succession throughout the autumn, and returned into heat; they will then begin a fresh growth, and will continue to flower for a long time. *Leonotis leonurus* treated thus, only being turned out of doors in the summer, may be had in flower from August to the end of November. There are two species of a half-Orchid genus from Brazil, which thrive exceedingly well in the conservatory in July, August, and September if now set growing in a brisk bottom heat and very rich soil. These are *Dichorisandra thyrsiflora* and *gracilis*, both with beautiful spikes of light blue flowers. The old *Costus speciosus*, by the same treatment, will come in very useful late in the autumn. As these plants, like the *Gloxinia*, require to be dry in winter, and may be kept where nothing else would grow, they are useful where room is scarce, and that is the case almost everywhere. Seeds of stove plants, or from foreign parts, may now be sown in well-drained pots, in peat and sand. Look over all plants regularly, and let everything be clean about them.

FORCING PIT.

As soon as the blooms are ready to expand the plants should be removed from close heat to a more airy situation for a day or two before they are brought into the conservatory or sitting-room. Syringe this pit at least once a day. Keep the plants free from insects. There are many plants, probably, that will force well which have not yet been tried.

PITS AND FRAMES.

Protect securely through the night, but give all the air possible during the day. Calceolarias and Heliotropes may be potted-off preparatory to being hardened for the flower garden. The whole of the Verbenas, Petunias, Salvias, and all the soft-wooded plants for bedding-out in the flower garden are best from spring propagation. These in store pots may now be introduced into heat for that purpose.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

WHAT Saturdays! The 11th distinguished by a rain that froze as it neared the ground, followed, as we expected, by open weather; and now, on the 18th, a deluge of rain and a hurricane that has tried trees, glass, verandahs, spouting, slates, and chimney pots, and sent them careering in many cases as if they had been so much gossamer.

The weather during the week enabled us to bring up to some extent arrears of out-door work—trenching and pruning, and even planting and transplanting, though we had rather have finished that some months previously. We would have planted a lot of Cabbages out, but the ground was still rather wet, and as we have at least three successions of young spring ones, and

a good number of Coleworts, which we protected a little from the frost, we have no occasion to hurry in the matter. The frost has as yet done us no harm in the vegetable way. We wish we could say the same of vermin, as mice and even rabbits attacked our Endive and Lettuce under protection. We are almost resolved in future to lift and protect no more Endive in winter, under similar circumstances. A fine lot placed in an earth pit, with old sashes over it, and covered with litter during the severe frost, has had the hearts nipped out most unmercifully, whilst much that was left where it grew with just a slight protection, has not been touched at all by the marauders. We have long found that whatever is taken extra care of, is more valued by mice as well as birds. The very idea of protecting makes them anxious to see and taste what is thus cared for. As to sowing out of doors, our ground is as yet too wet.

Parsnips.—We have just taken these up, as we wanted to put the ground in order, and a fine crop they have turned out. It may be fancy, but we always think that Parsnips are the better, and keep the better, when not taken up too soon. On the whole, we think the roots are more saccharine when used after the New Year, if taken up in November; but then we do not think they are so juicy, or so rich in flavour. The Parsnip, however, is one of those rich vegetables that, like the Vegetable Marrow, we cannot partake of often, and therefore we would be glad to receive opinions whether there is any valid reason, except its hardness, for allowing it to stand in the ground long after Carrots and other roots must be housed.

We allude to this all the more, because very much may often depend on very little things. A very clever farmer, who is very fortunate with his Mangolds, and uses them largely for his stock, takes great care to have them home dry, and built in triangular heaps, and thatched, but so that they shall not heat much. Slight heating, however, he considers of importance. Before Christmas the heads were just shooting a little, and there were little roots, about one-eighth of an inch in length, coming in little bundles here and there on the Mangolds, and he assured us that after they came to be in this slightly moving state, the cattle partook of them more eagerly, and threw much better on them. The matter is suggestive.

Variegated Kale.—How is it that in many cases a prejudice still exists against this beautiful vegetable, as tender when cooked as it is beautiful? Many grow the white and the red variegated varieties, but chiefly that they may use it for garnishing and dressing. Cooks say it is neither "one thing nor the other," looks sickly when cooked, and comes anything but the right colour. Now, we dislike ourselves to see sickly yellow Greens on the table, when they should be green, and when in all softish water a pinch of carbonate of soda, that will do good rather than harm, will keep Greens quite as green as they need be. A pinch of the same will secure a fine red or crimson-coloured dish of these red variegated Borecoleas, quite as good to eat as the green ones after they are frosted and properly cooked; and but for prejudice, a red or a white dish of these Greens might pass muster where the blanched Sea-kale is such a general favourite.

Spinach Beet.—This reminds us of another vegetable, and a very profitable one, that great numbers of families never use—namely, the Silver Beet. The leaves make an excellent Spinach all the summer, and the broad white footstalks, when separated from the leaves, and cooked when rather young, make an excellent continuation of and substitute for Asparagus and Sea-kale.

We have kept on successions of Sea-kale, Rhubarb, Mushroom, &c., in the Mushroom house, and made a bed for sowing Cucumbers. We would have made beds under glass for Radishes, early Carrots, and Potatoes, but the weather prevented our collecting leaves, and without them we could not do much towards forwarding these crops. After February we have had them early by merely covering with a frame, and husbanding what sun heat there was. They are all the better, however, of a little heat below them. A little bottom heat is useful for almost everything that is wanted early. Were we near a coalpit, where small coal is to be had almost for the taking-away, we would have shallow well-exposed borders heated beneath for many early vegetables that we are obliged to raise now with cumbersome unsightly dung beds. The dung, however, makes up for much of the labour and unsightliness; what gardeners would do without it in close-cropped gardens is more than we can tell, for even artificial manures will not answer always, or for every purpose.

We have sown little as yet in heat, except Cucumbers and Celery. It is bad policy to sow many crops early, and not be

able to find room for the plants. If they are not well treated, or suffer from confinement, they would have done better if sown a month later, when more room and attention could have been given them. Celery comes on so slowly that to have it early it requires to be sown thus soon. When we have sown even in December we have not had a run head. In fact, the running depends more on checks given to the roots than on early sowing. What is sown early grows very slowly; for mere general crops we have seen sowings in the end of March come in as early as plants from seed sown in February.

FRUIT GARDEN.

Looked over Grapes now becoming thin. A few bunches still hang in the orchard house, and would have been better, but some robins during the severe frost found a hole big enough for their little bodies. We are loth to meddle with them, for they are generally so innocent of wrong-doing to us.

Raspberries.—Took up and replanted a piece of Raspberries that was a little the worse of wear. We had previously secured a bearing plantation, so as to have no break in the supply. We had the white-flowering, large white-rooted *Convallulus* amongst the old plantation, and it had become so plentiful among the roots, that it beat us in summer to arrest its growth; and when once it was allowed to twine among the Raspberry stems it was vain to hope to paralyse the roots, the smallest piece of which will grow, and if not taken out of the ground it can only be killed by incessantly cutting off every shoot that appears. This is one of the most beautiful of our climbers in a wild state, and one of the worst of weeds to eradicate. We made sure that not a bit was left about the Raspberry roots, and where these were tolerably large we planted them so as to take a crop in the usual way; and when the roots had to be divided we planted and cut down, so that if they bear at all it will be on the young shoots in the autumn, which they are likely to do. They were planted in ground well trenched and manured, and mulched along the rows. The rows are $4\frac{1}{2}$ feet apart, and stakes are driven in, and long shoots or reds are tied along for the canes to be fastened to. This plan is as good as any; but as Raspberry plantations, if annually manured, last a long time, the best plan is to have a stout post at each end, and small iron posts between, and connect them with strained wire to fasten the canes to. At that width little will grow between the rows of Raspberries. We often plant in spring a single row of Cabbages that come in early in summer as the spring ones begin to fail, and then they yield a fine lot of sprouts in winter. No plantation of Raspberries thus treated will yield in proportion to a single row with plenty of room on each side, and therefore single rows, like single rows of Peas, will ever be the most profitable; but when much is wanted single rows round or in different parts of a garden, would be difficult to protect from birds, and that may be done when the plantation is all in one place.

Strawberries.—We have as yet done little with these, except securing all in pots, and keeping a lot under glass, with just a little heat below them to bring them on gradually. Some of our friends are vexing themselves that the old leaves are becoming withered, spotted, and anything but pleasant to look at. They need not trouble themselves on that account, for as growth commences and the flower trusses begin to show, fresh vigorous leaves will be produced. During winter we like all the old leaves to remain, as they act at least in the way of protection; but when we wish to start the plants for forcing we twist off these old withered leaves, allowing only the smallest and freshest in the centre to remain. For the same reason we do not give the final dressing to rows and quarters out of doors until fresh growth is commencing, when the old withered leaves are dressed-off and the surface mulching levelled, broken, and made neat. Ground may now be put in readiness for fresh plantations, bearing in mind that as it most likely will be unbroken again for two or three years, it will be advisable to trench it well and enrich it with rotten dung; and then if there is a good bed of young plants pricked-out in rich soil last autumn, these, if lifted with balls and planted carefully, will often fruit better than if planted-out finally in the previous autumn. All young plants do better when placed thickly, as it were, in a nursery at first, as the one protects the other; and in such a nursery bed it is easier to attend to their wants than when scattered over a quarter or a border. Putting the ground in fine order for the well-established plants to grow in at once in the spring is a consideration; so that in stiff soils especially, the first pricking-out, say 5 or 6 inches apart, and then raising again with balls, will be anything but labour lost.

Orchard Houses.—Most of our Strawberry plants are in the

openest orchard house, and, thanks to the snow, we did not as yet require to cover them there with any litter, nor yet the fruiting trees in pots, as the frost did no more than crust the surface lightly. We took advantage of the unfavourable weather, first to smoke the house most at liberty with Laurel leaves, and then, before the Strawberries were put in, we syringed the whole inside with hot water, in which a little soap was dissolved, about 2 ozs. to four gallons, using the water as hot as we could well do—from 160° to 180°, throwing it over the glass, woodwork, walls, and trees. Of course it would become cooler in passing from the syringe. The other house we could not do so thoroughly, owing to its containing things in a growing state, and there we washed the trees with a brush and warm water, with mere soap in it. When dry we washed or painted again with a weak solution of Gishurst, about 2 ozs. to the gallon, thickened a little with clay, and a little lime to give it a light colour. We have frequently used limewash, rather mild, alone, and with the best effects. We use the lime, however, chiefly for the colour, in order to keep the buds as backward as possible. We have had buds injured by using Gishurst at the strength of from 4 to 6 ozs. per gallon, and therefore we like to be careful. If the trees are thoroughly clean nothing is wanted, besides the washing, except in the way of precaution. A little clay thick enough to adhere is just as good for daubing up any inconspicuous eggs that may escape the brush, as anything else; and as on the closest scrutiny we did not detect a trace of an insect, but for making sure we should not have painted at all. The light colour imparted is, however, of some importance, as the blossoms will open later; and from this time forward, until they do open, the great point in these cold orchard houses is to keep them back as much as possible by all the air that can be given, unless when stormy or frosty. If there are not other subjects in the house, a few degrees of frost before the buds swell much will do good rather than otherwise.

We finished top-dressing the *trees in pots*, taking off all the mulching and a considerable portion of the surface soil with the fingers and a pointed stick, replacing it with fibrous loam and about a fourth part of sweet decayed dung, firming it well with a stick and mallet, and filling to within half an inch of the rim, or rather less, giving a little water only to those pots that were dry. We should have liked to have finished all the top-dressing before Christmas; but we did it as the weather was suitable for in-door work.

A few plants that were in small pots we shifted into others a size larger, using similar soil, but with less dung in it, and ramming it hard round the ball. We advise, however, that all such shifting be done at the end of October or the beginning of November if the plants are to stand in the house after shifting. No plants in pots are to be thoroughly depended on for fruiting well unless the roots kiss the sides of the pots, and this should be thought about in all potting.

If this can be secured, the mere time of potting is of less consequence; but the plants must be established under ordinary circumstances. For instance, we once had a nice crop of Cherries from plants in pots that had been grown in the open ground in a nursery during the summer, but were pinched-in and treated on Mr. Rivers's system. They had been taken up with good roots near home, but with nothing worthy of the name of a ball, and came to us in a neat package, the roots done up well in moist litter and fern, as far as we recollect, about the middle of March. We potted them carefully in rather small pots, laying out the roots carefully, and firming the soil as we proceeded, doing the most of it with our own hands. We then made a bed of warm litter and leaves from 18 to 24 inches deep, and plunged the pots into it, covering them over several inches, and putting in trial sticks so that the heat should not exceed at the hottest from 80° to 85°, giving no protection to the top of the plants except a net to keep the birds from the buds. By the time the buds began to swell, the heat of the bed was little more than the earth in the open air, and by that time the pots were becoming filled with fine roots. The pots were partly raised out of the bed, then altogether, and then removed to and plunged half way down in the soil of the house, and the crop was everything that could be desired.

We may here mention, that our pots are thus all partly plunged, chiefly for saving water, that these are allowed to let the roots out a little in summer at the bottom of the pots, are raised to break these roots in October or November, and that though we would wish to reshift, that most of our trees have been a number of years in the same pots, and have borne

heavy crops by the help of top-dressing and mulching in summer. If pruning and pinching were attended to in summer, little will now be required, and beginners should wait a month longer that they may see the wood buds better.

The above example will show what may be done, even now; but in the generality of cases, and where no such extra care can be given, we would advise those wishing for fruit in small pots, to let the plants remain in these pots for the season; but if very small make the hole large at the bottom, and either set the pot in the border of the house, or into a larger pot or box, so that the roots may pass through, and still those in the pots press against the pot. Much also may be done with repeated mulchings above the level of the pot; but of this and other matters in other departments, we must treat on another occasion.

Sulphurous Acid.—Wonders will never cease. We had hardly written the remarks lately on the deleterious effects of burning sulphur on all kinds of growing plants, than in the "People's Journal," of Dundee, we saw a notice of two pamphlets, issued by Dr. James Dewar, of Kirkcaldy, and Dr. Pearman, of Biggar, the one in the fifth, and the other in the seventh edition, both having had a large circulation, on the prevention and the cure of diseases by sulphurous acid, either in the way of fumigation or inhalation. While it is stated to be generally efficacious, it is particularly suitable in colds, catarrhs, diphtheria, fever, &c., and it is hoped it will be of much benefit in consumption.

According to Dr. Dewar the system can be conveniently practised as follows:—"Take a few red cinders on a kitchen shovel, and set this on a stool in the middle of the room. Then sprinkle flowers of sulphur in successive small quantities upon the cinders until the atmosphere is filled with fumes, but not disagreeably so. If fumes are rather strong the window or door may be opened. The process may be repeated; but a slight constant taint is recommended in the sickroom."

We presume that even such an amount of sulphurous acid as would be thus felt would make short work of any window plants. In this respect we believe that animal life is much harder than plant life. We have designedly killed every green leaf in a pit with burning sulphur, and then on clearing out we have found toads and mice alive. When we produce sulphurous fumes in our plant and forcing houses, we are obliged to use a low temperature, not liking even water to be above 170°, but rather lower than that, so that we can have the acid without the sulphur burning; and even for sickrooms it might be advisable to produce the fumes from the outside of a hot-water vessel instead of burning cinders, and then the same therapeutic effects might be secured with less annoyance.

Be this as it may, in the chief district of the straw plait trade, and where much cleaning and bleaching of the straw was done by burning sulphur in close rooms, whilst the little gardens shewed the prejudicial effects of the sulphur fumes, they seemed to exercise little prejudicial influence on the work-people. Indeed, when Luton, the great mart of this trade, had not as yet come under the management of a Board of Health, the comparative general health of the inhabitants, though the town was not very favourably situated otherwise as to sanitary matters, was often attributed to the sulphur used in the manufacture. In these days many are partial to tracing the accordances as well as the contrasts between vegetable and animal life; and we would merely wish to lay it down as a proved fact, that if men and women can stand a small dose of burning sulphur, and even be benefited by it, no growing plant can be exposed to such fumes without being injured, and often irreparably. We shall never forget the look of dismay presented by an old friend of ours, who, after benefiting by sulphur in rheumatism and lumbago, put a little of it among tobacco for smoking, to kill the insects on a petful of *Cinerarias*. If he did not kill all the fly, he did kill all the large leaves of the *Cinerarias*, rendering them useless.—R. F.

TRADE CATALOGUES RECEIVED.

William Paul, Waltham Cross, London, N.—*Select List of Vegetables, Flower, and Farm Seeds, Gladioli, &c.*

Charles Turner, Royal Nurseries, Slough.—*Catalogue of Seeds for the Kitchen, the Flower Garden, and the Farm.*

W. Cutbush & Son, Ilighgate, London, N.—*Catalogue of Select Vegetable, Flower, and Farm Seeds.*

John Scott, Yeovil, Somerset.—*Catalogue of Vegetable, Flower, and Agricultural Seeds.*

COVENT GARDEN MARKET.—JANUARY 22.

We can barely keep up last week's prices as regards the best articles, owing to a considerable quantity of late Grapes being thrown on the market, chiefly Lady Downe's and Gros Guillaume. Pines are quite sufficient for the demand. Foreign importations continue heavy. Cornish Broccoli is now very good.

FRUIT.

TO CORRESPONDENTS.

“We request that no one will write privately to the departmental writers of the ‘Journal of Horticulture, Cottage Gardener, and Country Gentleman.’ By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.”

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

BOOKS (E. E. W.).—“The Garden Manual” contains what you need probably about Roses. If you enclose twenty postage stamps with your address, you will have it sent to you free by post.

SUGGESTION (Ambrose).—We are obliged by your suggestions, and gratified by your kindly wishes. You will see, as the year progresses, that we have arranged for some of the additions you suggest, but to adopt them all would oblige us to enlarge the Journal and increase the price.

HEATING (Broughston).—You have arranged the piping, &c., quite correctly, and according to the usual mode.

CHINESE SUGAR GRASS (W. Chisholm).—Your experience of this agrees with that of all others. “It is neither useful nor ornamental” in this country, and may be numbered with Mr. Huilett’s other “Mangosteen affair.”

GROUND VERNICES (F. J. C.).—Yes, that which you refer to and all others are to be closed at the ends.

DYING & BOTANICAL SPECIMENS (M. A. H.).—To take specimens home in good condition you must have a botanist’s tin collecting box, or vasesum. You cannot preserve the specimens so as to retain their colours. Spread the specimens so that the leaves do not touch each other between two sheets of your paper; and press gently with a handpress or hot flat-iron. Afterwards place the paper under a gentle pressure until the specimens are quite dry.

STRAWBERRIES AND POTATOES (L. A. W.).—The following twelve Strawberries will suit you.—Knight’s Princess of Wales, Eclipse, Oscar, Premier, Rivers’s Eliza, Viscountess Henriette de Thury, Sir Charles Napier, La Constante, British Queen, Carolina Superba, Dr. Hogg, Frogmore Late Pine. The three early Potatoes you should grow are Coldstream Early, Royal Ashleaf and Walnut-leaved Kidney.

DISSOLVING BONES BY POTASH (A. Schreiber).—No one can tell the exact quantity of caustic potash needed, for bones vary in the quantity of phosphate of lime which they contain. Let every bone be coated with potash; and if they are not entirely dissolved add more potash until they are dissolved. The manure will benefit rather than injure fruit trees. (W. B. C.).—In our Journal published on the 2nd inst., and the preceding note, directions are given for dissolving bones by the agency of caustic potash.

VINES (W. C. D.).—We quite agree with your gardener about the Vines which you have for early forcing, with the exception of Black Prince, which we, in opposition to the opinion of some, regard as an excellent Grape. Lady Downe’s is not adapted for early forcing, and what you say of the other two is very just. It is a very dangerous matter to advise the grafting of Vines, as the influences that various stocks exert on the scions are so different, and in some cases so very detrimental. Muscat Hamburgh is an excellent Grape and might do; you should get the Royal Ascut which we have just seen quite ripe, and most deliciously flavoured, on Vines which were planted out from 4-inch pots in May last. This will prove the most valuable of all Grapes for early work.

NEWLY-ENCLOSED GROUND (H. W.).—If you enclose five postage stamps with your direction, and order “Allotment Farming,” you will have a book sent you free by post, which details the information you wish for.

THEORY OF DRAINING (R. A. of R.).—How it benefits soils is fully explained in Johnson’s “Science and Practice of Gardening.” That earthenware pipes do admit the surplus water through their sides is proved by the quantity poured out from the pipes; and as they exhaust the surplus water in their neighbourhood other and more distant surplus water subsides thither, just as an open ditch or drain carries off water, and the excess of water in the soil near continues to ooze into the ditch or drain.

IVY (R. Pullen).—What you require we think is in our No. 201, published on January 31, 1885.

DESTROYING CRICKETS IN A CUCUMBER PIT (J. E.).—Try placing phosphorus paste spread on slices of bread in the pit, as recommended on page 467 of our last volume, or 1 oz. of arsenic and a little ground aniseed and caraway seed mixed with half a pint of oatmeal, of which they are very fond. Mix and lay on pieces of paper, but take care that no domestic animals partake of the poisoned mixture. It is a good plan to tempt the crickets with the oatmeal and aromatics, without the arsenic, for a night or two before using the poisoned mixture.

ORCHIDS FROM SEED (L. H.).—Many species and many hybrids have been raised from seed in this country. Mr. Downy, at Messrs. Veitch’s Nursery, has been especially successful in raising hybrids. Mr. Williams, in his “Orchid-Grower’s Manual,” says:—“Many kinds seed freely if the flowers are set, producing many seeds in a pod. When ripe the seed should be sown; but it requires great care, as it is not so easy to raise as that of many other kinds of plants; some of the kinds are a long time in germinating; I have known Orchid seeds lie twelve months before they made their appearance. To watch their progress when up is, however, highly interesting—first, the formation of pseudo-bulbs, then their advancement towards flowering, are processes full of pleasure yielding anxiety. The best place to sow is on the top of an Orchid pot, where the seeds will not get disturbed; let the peat be in a rough state; do not cover the seed, but give a little water with a fine-roseted pot, just to settle it in the peat; some rough blocks of wood on which another plant is growing afford a capital situation to sow upon; they should always be kept a little moist; and of such as are sown on pots in the same way, when the plants are strong enough, pot them off into separate pots, or place them on blocks in the material recommended for the parent. In potting and taking them up care must be taken not to break the roots.”

CHAUMONTEL PEARS IN JERSEY (O. P.).—We quite agree with you in thinking that the pyramidal form is much more graceful than the bush form, but the latter is as certainly less liable to have the fruit shaken off by high winds. Bush-formed trees shelter one another, but pyramids do not. The most prevalent and most powerful winds in Jersey we presume are from the S.W., and as your walls are 15 feet high, you may have some pyramids on that side near the wall.

TURFY PEAT FOR VINE BORDERS (An Inquirer).—If the soil of the Vine borders is very stiff, such as a clayey loam that adheres in large clods, then turfy peat or rather turfy heath soil will be beneficial. Such peat formed under water as that cut for fuel, will be of no advantage, but quite the reverse.

STEALING TURNIPS (S. de B. J.).—It is equally a theft whether you eat the Turnip in the field where it is grown, or take it away unladen. A bush was formerly hung up where wine, &c., were sold; and the proverb, “Good wine needs no bush,” implies that where goods are excellent they attract attention without any public announcement.

ROSE (Cyril).—“Mossy de Meaux” is the same as De Meaux or Pompon. Mr. W. Paul or any other florist can supply it. It is only fit for edgings.

ROSES IN POTS (Columbia).—“The Roses in 3-inch pots must necessarily be weak. It is best not to bloom them in their weak state. They should be shifted into 6 or 8-inch pots, and the growth of wood should be encouraged. As they are to be placed under shelter in winter, ripeness of wood does not signify so much as if they were to be wintered out of doors. The sooner they are put in larger pots the better. They may be sunk in the ground in the pots. Put some rotten dung under the pots for the roots to enter on passing through the holes in the bottom. When the plants are taken up to be housed in winter, their roots may be cut off level with the bottom of the pots. Roses planted out do better in summer than Roses in pots. Usually there is no difference in the treatment of Roses on Manetti stocks and Roses on their own roots. Roses on their own roots have this advantage, they may be cut down close if their wood is not good. The Tea Roses you named are good. Add these—Bouton d’Or, a beautiful little golden yellow Rose; Souvenir d’Elise, Adam, Rubens, Sombreuil, Elise Sauvage, Vicomtesse de Cazes, Souvenir d’un Ami, Homer, Madame Joseph Halphen, President, Triomphe de Rennes, Céline Forestier. Tea and Tea-scented Roses are the best for house culture. As they are deficient in deep colours, add some of the Roses named on page 55. Bourbons and China Roses are scentless, and should not be retained except for distinctness. If Roses are to be kept in pots continually they must be annually potted in fresh mould.—W. F. RADCLIFFE.”

ROSE TRIOMPHE DE RENNES, &c. (L. C.).—“I have a great many plants of Triomphe de Rennes. I have never known the blooms crack or be defective. A north-east wall is not a good place for a Tea-scented Noisette. Put it against your south-east wall. Perhaps a little root-pruning may stop its cracking. I have a small plant of Climbing Devonensis which I have not yet bloomed. Mr. Curtis gave me two fine Briar plants of it when I was at Rushton, and both died. I do not believe it to be a humbug. I should not cut it much, but prune it as if it were a Hybrid China pole Rose. It must have room to grow. It will most likely bloom well this summer, if not much cut with the knife,

Put your Marechal Niel against your south-east wall, spread it out, and nail it against the wall as if it were a fruit tree. Do not put any manure to your Climbing Devonensis till it has formed its buds, and then manure according to products. To overdo is needless to undo. It rarely occurs in the matter of manuring.—W. F. RANGLYRE."

PLANTING IVY (*Idem*).—If rooted in pots the plants may be turned out and placed where they are to remain now.

GAS HEATING (*W. Farley*).—You may heat your viney with gas, if you have a sufficient quantity consumed, and the fumes carried out of the house, as we have often pointed out.

HEATING BY GAS (*O. H.*).—The whole subject of heating stoves by gas for plant houses has lately been treated on, and plans, &c., given. We think it likely that the reasons why the gas in your case comes back into the house and will not go out at the pipe in your friend's house are these:—First, most likely the burners are too near the floor, the place where the burners are, not sufficiently shut in, and the flue pipe communicating with the burners from the outer air may be too much at times. If the burners are raised a foot above the floor, and the chamber, when the burners are lighted, is kept close, a small hole near the floor will be sufficient for combustion. Secondly, the burned gas will go away most effectually when the burners act on a concave bottom like a reversed funnel, and the discharge pipe goes from its centre, and after passing through the stove boiler goes at once perpendicularly out of the house. Let your friend first try the perpendicular pipe as an outlet, and do away with the horizontal one. We are glad your stove acts.

HOUSE FOR CUCUMBERS AND MELONS (*J. D.*).—Your plan will not succeed, proposing as you do to grow Melons and Cucumbers over your bed in front, with hot-water pipes beneath it, and also have a Peach and Apricot tree trained against the back wall, and Peach and Plum trees in the end-stem or cord-on style up the rafters. Apricots will scarcely stand any artificial heat until after the fruit is set and swelling, and, therefore, to have Cucumbers and Melons moderately early, you must give up all thoughts of Apricots. Peaches and Plums would only succeed if you were satisfied with late Cucumbers—that is to say, the temperature of your house must not be above 50° with artificial heat until all the fruit is set, and the second swelling must commence before the heat is much above 55° at night; but then that would not do for Melons and Cucumbers, which would need some 10° more heat. This moderately early crop of stone fruit, and late crops of Melons may be the object: at any rate, with two 3-inch pipes in the chamber beneath the bed, and outlets from it into the atmosphere of the house, there will scarcely be half heat enough for early Cucumbers and Melons. With that house merely 8 feet wide, if Melons and Cucumbers are to be trained under the glass, there will be no light for anything after the plants are established. Such a house with present arrangements would do for medium early Cucumbers, Strawberries, Kidney Beans, &c., on the back wall, and then would come in for keeping bedding plants in winter; or it would do admirably for a stone-fruit house, especially for Peaches and Nectarines, planted out or in pots, but we have little faith in the Cucumbers and stone fruit together.

HEATING A SMALL HOUSE BY A PROPAGATING TANK (*A Novice*).—We surely must have made a mistake in our references, but as you spoke of heating your tank from a boiler, it is probable we meant to refer you to the answer to "W. A. O.," which follows the answer to yourself in page 32. We have read your letter over twice, and we feel at a loss, keeping economy in view, and your own plans, how to advise you better than we have already done. For a house 12 feet by 8, with a walk in the centre, and a platform on each side, half of the back platform to be appropriated to a propagating tank, and as you tell us, you have as yet resorted to no mode of heating, our great difficulty is, how to reconcile your own proverb, "Poor people must be poor welders," with your proposal to erect a boiler and a chimney at the west end of this house, for heating this 6-foot tank, and by means of that heating the house when it was required, and when not used for propagating purposes. As to this heating the tank there can be no question; the question is, the great labour for such a small return. We recommended a tank much shallower, because in a deep tank the bottom water is never so hot as that at the top. Your proposed arrangement as to making the tank of wood lined with lead, and covering it with slate, is all right enough, so far as giving heat to your cuttings is concerned. These cuttings we presume you will enclose with a wooden case at the sides, that again covered with glass, and we would recommend you not to have these glasses hinged on, but in 18 or 24-inch lengths, so that you can lift them off and reverse them when you think proper, presenting the dry side to the cuttings when there is too much damp on the under side. At times the glass might even require a cotton cloth over it, especially at night. So far, provided the tank is heated for your cuttings, there can be no question of that answering, but formed of wood as you propose, and covered-in with glass—say from February to the middle of April, you would not obtain heat from that tank to keep spring and late winter frosts out of your house. The matter would be different if your tank were of iron, or even of bricks and cement, but little heat would come through lead and wood, and not enough would pass through the glass unless the tank were over-hot. If you heat the tank in the way proposed, you would require two 3-inch pipes in the house besides, with valves so as to use them or not. If near a kitchen fire, the supplying the tank with hot water is a good plan, and then you might have a small flue below the pathway. We think we could do all you want by means of a brick or an iron stove in the house, the heat from the top to be made available for the propagating bed. To secure cleanliness, and as you do not care about a fireplace outside at the end of the house, we would dispense with the tank, pipes, and boiler, make a hole in the wall outside, make a small furnace there, take a flue from it 6 feet long, return it to a small chimney inside or outside the wall, covering the flue with strong tiles or stone, and leave the outside of the flues exposed, so as to give heat to the house. If there is a space between fill up with clinkers, and plaster smoothly over. Then lay a course of bricks all round the outside of your flue in Portland cement, cover the tops of the flue with a layer of the same cement, and thus you will have what will act as a shallow tank, and the bricks round the side will do for setting your little boxes on. Place brickbats, &c., in your tank, cover with rough clean gravel, then with finer, and then with some inches of clean sand; and provided you can pour water when needed into your tank, you will have a first-rate propagating frame, and at less expense than the boiler, &c., would cost you. If the place is warm and close, deep plunging is unnecessary. We should say from 3 to 4 inches of sand—nothing is more cleanly—a pipe

and a funnel to get water at times to the bottom of the bed above the flue is all that will be necessary. When you want more heat in the bed than would suit the house, leave air on night and day. When not wanted for propagating, then the frames of glass being moved, a very little fire would make all right. If you still, however, resolve on your boiler and wooden tank, let us advise you to have a small boiler and a small fireplace, and to take pipes through the house as well, and so that you can heat tank or house independently of each other, a very easy matter to do even economically, in a 50 or 60-foot house, but not in a 12-foot one.

NEPENTHES AND ELLAGIA CULTURE (*E. M. L.*).—Pitcher-plants, though delighting in moisture, require good drainage. The pot ought to be filled with broken pots to one-third its depth, placing the largest pieces at the bottom and the smallest at the top. A suitable compost is formed of chopped sphagnum and fibrous brown peat in equal parts, adding one-sixth of charcoal from the size of a hazel nut up to that of a walnut, and a like proportion of silver sand. The compost should be made firm, and raised in the centre of the pot in the form of a cone rising above the rim. Like Orchids, the Nepenthes require large pots for the size of the plants, and their fibres only should be covered with the compost. The plant may be thus potted in March, and should be carefully watered, the compost being sprinkled with water through a fine rose occasionally to keep it moist. The atmosphere should be kept moist and rather close, but a moderate amount of air should be given in favourable weather, without lowering the temperature or making the atmosphere dry. When the plant is growing freely the pot may be set in a wide shallow saucer, which may be kept full of water all summer. It is well to keep the atmosphere moist by sprinkling the paths, walls, and every available surface twice or thrice a-day with water, and by means of evaporation troughs. Moisture thus supplied is better than heavy syringings, at all times injurious, or even lightly syringing the foliage; but an occasional light syringing will do good, and may be given twice a-day in hot weather, more especially if means for creating a moist atmosphere are confined to the evaporation of water sprinkled on the floor and walls. When growing, a brisk heat of 60 to 65° by night in spring, and of 70° in summer, with an increase of 10° by day without sun, or when cloudy, and 15 to 20° on clear days, is necessary for a good growth. The winter temperature may be 60° to 70°, and at that season the plant should have a considerably drier atmosphere, but not so dry as to affect its foliage. Slight shade from bright sun is necessary.

SONERILA MARGARITACEA CULTURE (*Idem*).—The pot should be well drained, placing a large crock over the hole in the bottom, and then some rather large pieces of broken pot, and enough small pieces to fill the pot to one-third its depth, and over this drainage a little moss may be placed. A compost of two-thirds sandy fibrous peat, and one-third turfy loam, with a little leaf mould, and enough silver sand to make the compost light, will grow the plant well. The compost should be broken and made fine, and well mixed. Pot in spring, removing as much of the old soil as practicable without disturbing the roots much; and in potting keep the centre slightly elevated, and make the soil firm but not very tight. Be careful not to overwater, merely keep the soil moist until the roots are working in the fresh soil, but when established give liberal supplies, taking care not to make the soil sour. The shoots when sufficiently long may be potted down, and they will root from the joints. Do not syringe overhead, but keep up a moist atmosphere by sprinkling the floors, walls, &c., with water twice daily. Afford a light situation near the glass, and one which is also moderately airy. In winter be careful not to overwater. An ordinary stove temperature is suitable, or from 60 to 75° in winter, and 65° to 85° in summer.

VINE LEAVES RUSTY (*A Young Gardener*).—Without seeing the leaves we cannot form an opinion as to what is the cause of the appearances.

FEEN CULTURE (*Idem*).—*Adiantum cardiolobum, concinnum, macrophyllum, and trapeziforme, and Pteris tricolor* succeed admirably in a stove temperature. We should conclude, from the young fronds perishing as they unfold, that the atmosphere is not warm enough, and that the plants are syringed overhead. We should advise you to pot all of them early in March. The plants being turned out of the pots, take away as much of the old soil as can be done without injuring the fibres, and place them in clean pots with a large crock over the hole or holes, 2 inches deep of rather large crocks over that, and then small pieces sufficient to fill the pot altogether one-third its depth of drainage. Over the drainage a thin layer of cocoa-nut fibre refuse or sphagnum may be placed. Use for potting a compost of two-thirds fibrous brown peat, and one-third turfy loam, pulled to pieces with the hand and made fine, to which add equal parts pieces of sandstone, from the size of a pea up to that of a hazel nut, and silver sand equal to one-fourth the peat and loam, mixing all well together. In potting make the soil rather firm, but not very tight, and do not bury the plants deeply: at the same time avoid potting high. Give a gentle watering, and do not syringe the plants over the foliage, but sprinkle the paths, walls, &c., with water twice or thrice a-day. Assign them a position near the glass, with room between the pots and the glass for the fronds to develop themselves. Be careful not to overwater until the roots are working in the fresh soil; but when the soil becomes dry, and before the foliage flags, give a good supply, sufficient to show itself at the drainage. When growing freely they will need to be well watered. Give a moderate amount of air, but avoid cold draughts and an excessive amount of air, so as to suddenly cool and dry the atmosphere. A temperature of from 60 to 65° at night, and of 70 to 75° on cloudy days, and 75 to 85° on clear days, with air, will grow them well. They must be shaded from the sun daily, from 8 A.M. to 5 P.M., from March to October. The atmosphere must be kept moist.

MOVING DAMSON TREES (*J. A.*).—If you can lift the trees with a good ball, we should recommend your moving them into the orchard; if you cannot make sure of a ball leave them where they are, give each tree a mulching of well-rotten manure, and avoid digging the ground in future, as it injures the roots. Digging the ground about fruit trees is bad.

PLANTING VINES (*Idem*).—In planting a new house we should certainly plant a Vine or two of Lady Downe's. It succeeds in the same house with the Black Hamburgh, but requires fire heat. The Lady Downe's is a good bearer; the berries not so large as those of the Black Hamburgh, and the bunches are not so heavy; but in weight per Vine it is nearly equal to the Hamburgh. The Vines you have will do for planting if well ripened in wood and healthy.

VINES WITH CUCUMBERS (*W. K.*).—You may grow Cucumbers and Vines together; but it is not desirable in your case, as the Vines will, if they

grow well, reach to the full extent of the rafters the first season, and to encumber the rafters with Cucumbers would tend to foster red spider and thrips. Unless you can keep the Cucumbers distinct from the Vines, do not attempt them; but it pays best to grow one thing well rather than two or more indifferently. Give the Vines every chance, and if you have Cucumbers let them be secondary to the Vines.

SIEVE OF APPLES (J. A.).—A sieve contains seven imperial gallons.

CINERARIA FLOWERS PETALLESS (J. W. B.).—We do not think all the buds on the specimens sent would not have had petals—indeed, some of them have, but many of them are blind. The specimens are fully a month from the blooming stage. We should attribute the flowers having no petals to defective impregnation of the flowers producing the seed, and we should think the fault lay with the pollen. The specimens show the plants to be very healthy and fine, and we think if you will have patience that you will yet have a fine bloom.

APPLE TREES COVERED WITH MOSS (B. Fran.).—The chief cause of the stems of fruit trees becoming covered with moss is the soil being wet and undrained. Moss will also luxuriate on trees in poor light soils if not liberally manured. To free the trees of the moss you should make them quite wet by syringing with water, and then, or after a heavy rain, when the branches are wet, sprinkle each tree with quicklime, covering it as equally in every part as possible. A rather thick coating should be given, and lime of the most caustic quality is best. We cannot account for your not being able to grow Parsley, having no data.

PROPAGATING CHRYSANTHEMUMS (B. Sandown).—The best way to propagate *Chrysanthemums* for out-door purposes, is to take off the well-rooted short-jointed stiff suckers and pot them singly in small pots. Place them in a cold frame, keeping them close for a time, or until they commence growing, when air should be given and the plants well hardened-off before planting out. The suckers may be taken off from now up to April. In frosty weather the frame should be covered with mats. Failing a frame, the suckers may be planted about 3 inches apart in light soil in a sheltered situation, planting them out with a ball in April, or when they become well rooted.

PEAR TREE SUCKERS (Idem).—The suckers that rise from old Pear-tree roots ought to be cut off quite close to the roots, the soil being removed for the purpose. If cut off at the surface they only increase in number; either dig or pull them up.

SAPONARIA CALABRICA SOWING (Idem).—You may, if your soil is light and the ground not very wet, sow the seed early in March; but you will gain nothing by sowing early if the ground is wet and cold. The plants will grow much better if the seed be not sown until the beginning of April.

PLUM GRAFTING (H. L., Oron).—Grafting is not a desirable mode of propagating the Plum, for, should the grafts take, gum or canker is apt to ensue. For success the scions should be taken off early, now being a good time, and it ought not to be deferred beyond the beginning of February. The stocks, too, should be headed down now near to the place where the scion is to be put on. If the stock is headed down, or the scion taken at the time of grafting, or both, success becomes very uncertain. The proper time to graft is when the sap is rising freely in the stocks, which is generally in March. Budding may be performed in July, when the bark parts freely from the wood. In grafting, if dry weather follow, success is rendered more certain by drawing the soil up in the form of a cone over the clay. You will not succeed with grafting the old Green Gage Plum tree. You might probably succeed if you were to insert some buds on the young wood.

MAGGOTS IN APPLE TREE (Idem).—We think the fleshy white grub is the larva of the Apple-borer (*Saperda bivittata*), a brown and white-striped beetle that deposits its eggs in the collar of the tree in June and July. The grub takes two or three years to go through all its transformations, penetrating the stem, and causing the death of the tree by consuming the alburnum. You operated just at the right time. Any remaining may be destroyed by thrusting a piece of wire into their holes. It is said that washing the stems with a solution of 1 lb. potash in four quarts of water will prevent attacks. We should cover the stem from which the bark is gone with clay, which, no doubt, would encourage the formation of fresh bark more speedily than were the stem left bare. Grafting clay will do.

LIQUID MANURE FOR FORCED RHUBARB (Idem).—In the forcing of Rhubarb on dung in a frame, watering with liquid manure, if not powerful, could not do any harm. We are not certain it would do good.

BEDDING PLANTS IN PIT (Man of Kent).—Your *Pelargoniums* that were cut back, and now have small leaves about the size of a shilling, will not give you any cuttings in spring. They will not do more than make good plants by bedding-out time, and if you take cuttings you will spoil the plants for making a good display in summer. You could not force the old plants without spoiling the cuttings, and we would, therefore, continue the plants in the pit, and let them become fine plants, which are far better for making a display than a lot of late-struck cuttings. You could make up a bed for cuttings, and some of the plants would certainly afford a supply; at least the cuttings in boxes will need heading-down, and they will afford excellent cuttings. One frame could be used for this purpose, and the other would serve admirably for your *Pelargonium* cuttings in boxes when you pot them. It is much too soon to pot them off; March would be a good time with you. The *Calceolarias* would do admirably in the cold frame, and are better without heat, but will need protection from frost. *Calceolaria* cuttings now put in will make fine plants by bedding-out time. They succeed without heat. The fibrous loam would answer admirably for potting off the *Pelargonium* cuttings, and for the potting of the old plants in April; but we would take equal parts of the fibrous loam, of the half-decayed turf chopped fine, and leaf mould, adding a liberal admixture of Reigate sand. The turf will be in fine condition by autumn. You will need all spare frame room for the *Verbena* cuttings, *Lobelias*, &c. The Mrs. Pollock *Pelargonium* not cut back will afford you cuttings, but we would not take them off until you can give them a gentle heat, and it will do when you make up your bed for cuttings in March. The cuttings would not succeed if put in pots and kept where the old plant is stationed. The old plant would do better in the pit, and the cuttings in a hotbed.

BEGONIAS (Judy).—We think Marshalli, Lowi, President Van den Hecke, and Pearcei are as handsome as any of the fine-foliaged *Begonias*. They will do fairly in a room, but to succeed will require to be kept in a glass case and in a warm room, or heated plant case.

COMPOST FOR THE TOMATO (J. H.).—The Tomato succeeds in a compost of two-thirds turfy loam and one-third leaf mould or well-rotten manure, well incorporated. To obtain strong plants for planting out in May it is necessary that the seed be placed in a hotbed, and the plants potted-off when large enough, and forwarded in heat, hardening them well off before planting out.

SOIL FOR MELONS (Idem).—The best soil for Melons is a strong unctuous loam, the top 3 or 4 inches of a pasture. Cut in autumn and placed in a heap, this will be in fine condition in spring.

SELECT RHODODENDRONS FOR BEDS (M. H. R.).—We would not have groups of one kind unless there were a number of beds, then a group of each of the following would be very effective:—*Blandyanum* superbum, light crimson, dwarf habit; Comet, scarlet; *Atror-sanguineum*, blood red; *Barclayanum*, reddish rose; John Waterer, crimson; *Maculatum* purpureum, purplish rose, spotted; Victoria, plum; William Downing, dark purple; Lady Lopes, waxy rose; Alarm, centre white, edged with light scarlet; Blanche Superbe, waxy white; and *Papilionacea*, pale lilac, changing to white. If you require more variety you may add Neilsoni, rosy lake; Madame Titeux, vivid rose; Toward, rosy lilac; Ninon de l'Enclos, rose; *Picturatum* superbum, white, dark spots; Princess of Wales, magenta edge, white centre; Leviathan, pinkish white; Jenny Lind, rose; Duke of Cambridge, crimson scarlet; Chloë, crimson lake; Lady Dorothy Nevill, purple spotted with black; Hogarth, rosy crimson; and Faust, lilac blotched. We should prefer plants one or two years from the graft set with bloom buds.

SELECT EVERGREEN SHRUBS (Idem).—*Cotoneaster* *Simmonsii*, *C. microphylla*; *Daphne* *oleoides* variegata; *Colletia* *bicentenaria*; *Viburnum* *tinus*; *V. tinus* *atrovirens*; *V. tinus* *strictum*; *Double-flowering* *Furze*; *Spartium* *junceum*; *S. multiflorum*; *S. scoparium*; *Raphiolepis* *ovata*; *Skimmia* *japonica*; and variegated and green-leaved *Hollies* in great variety. The following are good:—*Ilex* *latifolia*, *I. Tarago*, which have very large leaves and do not stand wind well, therefore require a sheltered situation; *I. altacalensis*, *I. balcanica*, glabra; *Hodginsii*, *maderensis*, *nigrescens*, and *Shepherdii*, which have fine broad leaves; *I. crassifolia*, *myrtifolia*, *ciliata*, and *angustifolia* have small leaves; *I. Deningtonensis*, which has long narrow leaves, and *I. Fisheri*; *Gold-edged*, *Gold Queen*, *Gold-blotched*, *Handsworth* *New Silver*, *Silver Queen*, *Silver-edged*, *Silver-blotched*, *Gold-blotched* *Screw-leaved*, and the *Gold* and *Silver-edged* *Hedgehog*. In addition to the above there are *Aucuba* *japonica*; *Arbutus* *undecolor*; *Berberis* *Darwinii*, *B. japonica*, *B. Bealii*, and *B. trifoliata*; *Buxus* *marginata*, *sulphurea*, *aurea*, *argentea*, and *Handsworthiana*; *Desfontainia* *spinosa*; *Escallonia* *macrantha*; *Enrya* *latifolia* variegata; *Ligustrum* *japonicum*; *Cerasus* *laurocerasus*, and *vars. colchicus* and *foliis* variegatis; *C. ilicifolius*, *C. lusitanicus* *myrtifolius*; *Chamaebatia* *foliosa*; the gold and silver variegated varieties of *Eunonymus* *japonicus*; and *Berberis* *agnifolium*. If you wish for *Conifers* you may plant *Abies* *canadensis*, *A. morinda*, *A. Menziesii*, and *A. Douglasii*; *Arcaeria* *imbricata*; *Cedrus* *deodara*; *C. Libani*; *Cryptomeria* *japonica*; *Cupressus* *Lawsoniana*, *C. macrocarpa*, *C. majestica*; *Chamaecypariss* *thurifera*; *Juniperus* *chinensis*, *J. Sabina*, *J. excelsa*, *J. suecica*, and *J. virginiana*, and *virginiana* *glauca*; *Picea* *nobilis*, *P. Nordmanniana*, and *P. pinsapo*; *Pinus* *austriaca*, *P. cembra*, *P. excelsa*; *Taxus* *adpressa*, *T. fastigiata*; *Thuja* *occidentalis*; *Thuja* *Loblii*, *T. occidentalis*, *T. Warreana*, *T. orientalis*, and *T. aurea*; *Wellingtonia* *gigantea*.

SELECT DECIDUOUS-FLOWERING SHRUBS (Idem).—*Double-flowering* *Peaches*; *Calycanthus* *floridus*; *Cerasus* *japonica* *multiplex*; *Chimonanthus* *fragens*, should have a wall with south aspect, as the flowers are produced in winter; *Crataegus* *oxyacantha*, *Double Red*, *Double Scarlet*, *Double Pink*, and *Double White*; *Cydonia* *japonica* *alba*, and *C. japonica* *rosea*; *Cytisus* *alpinus*; *Daphne* *mezereum*, and its white variety; *Deutzia* *gracilis*, *D. scabra*, *D. crenata* *flor-pleno*; *Forsythia* *viridissima*; *Genista* *tinctoria* *flor-pleno*; *Hibiscus* *syriacus*, *double* and *single* varieties; *Hydrangea* *japonica*; *Kerria* *japonica* *flor-pleno*; *Leycesteria* *formosa*; *Magnolia* *conspicua* *Soulangeana*; *Myrica* *gale*; *Paeonia* *Moutan* varieties; *Philadelphus* *coronarius*, and its *double* variety; *Prunus* *spinosa* *flor-pleno*, *P. triloba* *flor-pleno*; *Rhus* *cotinifera*, *R. elegans*; *Ribes* *aureum*, *R. sanguinacum* *album* and *atro-rubrum*; *Spiraea* *callosa*, *S. corymbosa*, *S. arifolia*, *S. prunifolia* *flor-pleno*, *S. salicifolia* *paniculata* *alba*, and *S. hypericifolia* *crenata*; *Syringa* *persica* *alba* and *laciniata*, *S. vulgaris* *alba*; also *Lilacs* *Charles X.*, *Dark Blue*, *Double Purple*, and *Dr. Lindley*; *Viburnum* *opulus*, *V. opulus* *nanum*; *Weigela* *rosea*, *W. amabilis* *alba*, and *W. Van Houttei*.

LILUM GIGANTEUM (C. W.).—You have done right to give but little or no water during the winter. In February we would advise you to shift it into a pot a size larger, in a compost of turfy loam two-thirds, and one-third very rotten manure or leaf mould. In potting you may remove all the loose soil, but do not disturb the roots more than can be helped. Good drainage is essential. When it is growing water it abundantly, and set the pot in a saucer of water. After growth keep dry and expose fully to light and air. Do not throw it away, but give every encouragement to growth; let that be well ripened, and your plant will assuredly bloom.

CYCLOPS AFRICANUS (Sandown).—You would have done well to have potted it so that the corm would have been covered with soil. It commences growth in autumn. Your bulb will probably remain dormant until next autumn. We would plunge the pot out of doors in an open situation, but shaded from the fierce rays of the sun at midday, plunging so that the rim of the pot will be level with the surface, and cover the pot and for some distance around it with leaf mould or cocoa-nut fibre refuse 2 or 3 inches thick, leaving it there until next autumn. If you grow it indoors you should keep the soil moist. No supplement to the "Cottage Gardener's Dictionary" has been published.

CLEMATIS FOR TRAINING ON TREES (M. H. R.).—The new Clematises are not suitable for such a purpose, but need open situations. *C. montana*, *C. montana* *grandiflora*, *C. florida* *plena*, *C. vitalba*, *C. viticella*, and *C. viticella* *flor-pleno* and major would probably succeed, and so will all if the situation be open, or but partially shaded. All are quite hardy.

NAMES OF FRUITS (A. Nottice).—1, Beurre Diel; 2, Passe Colmar; 3, March Bergamot.

NAMES OF PLANTS (J. W. W.).—*Calceolaria* *rimosa*. (N. W.).—1, *Asplenium* sp.; 2, *Sonerilia* sp.; 3, *Eranthemum* *leucocentrum*; 4, *Gymnosplenium* *Verschaellii*; 5, *Selaginella* (bad specimen); 6, *Selaginella* *Martensii*; 6, *Asplenium* *nidus* (?); 8, *Adiantum* *cuneatum*, var. 9, *A. garden* *Pelargonium*; 10, *Doodia* sp. Send better specimens. It is not possible to identify Ferns from barren fronds in a young state with precision.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

GAME FOWLS.

CUP AND PRIZE SORTS AND COLOURS.—No. 1.

1. BROWN REDS.—These are essentially the Dark Reds, and are often so termed.

Cock.—General colour a rich dark brown red. Beak dark; upper mandible darkest. Comb, face, wattles, and deaf-ears all of a darkish gipsy-red colour. Eyes large, bold, full, and of a very dark blackish brown; the pupil not visible in the eye. Neck-hackle, or mane, rich dark brownish red, thickly striped with dark stripes under the outside feathers—"cut out" dark. Shoulders generally of a dark brown maroon red, but often of a rich orange red. Back a rich dark brown red, darker than the other parts of the plumage. Upper wing dark brownish purple red, or of a rich orange red in the lighter birds. Lower wing invariably of a dusky, smoky, very dark brown. Breast and thighs either red-brown, streaked with darker brown, or of a clear red-brown; any black streaks or markings objectionable. Tail dark greenish black, with dark fluff or down at the roots. Legs, feet, and talons, or nails, of a dark iron-brown or blackish bronze.

The wing often has a greenish bar, but the hardest birds are without this as a rule.

Hen.—General colour dark blackish brown, streaked, grained, and pencilled with a rather lighter brown on the dark ground. Comb, face, gills, and deaf-ears of a dark gipsy-purple colour, never red. Eyes large, bold, and full; as the cock's. Neck-hackle a golden-coppery dark red, thickly striped with very dark stripes. Breast and thighs dark; the former streaked with lighter brown on the dark brown ground. Legs, feet, and claws, talons, or nails, as in the cock.

Light nails or talons are very objectionable in this breed, as is a light beak or eye.

2. BLACK-BREADED REDS.—These should be essentially the bright reds, neither too light or pale, nor dark or dull.

Cock.—General colour a rich bright red. Comb, face, gills, and deaf-ears bright red. Eyes always red, either bright red or dark red. All other colours of eyes, as yellow, bay, or light brown, are inferior. Neck-hackle, or mane, rich bright red, lighter towards the shoulders, and striped underneath with dark blue stripes. Back, shoulders, and upper part of wings a bright full red, rather deeper in colour than the hackle or mane. The wings with a bright steel-blue bar across them. Lower part of wings a rich reddish bay or rich reddish chestnut colour, darker underneath. Wing-butts very dark brown. Tail dark greenish black, with not too much fluff at the roots, and that scanty and of a whitish or yellowish grey dun colour. Breast and thighs of a dark bluish black. Legs, feet, and claws willow or dark willow colour.

Willow legs are the favourites, but there are good birds with all colours of legs. Good red eyes and a bright red colour are the true requisites for Black-breasted Reds.

PARTRIDGE RED HEN.—General colour a rich reddish Partridge-coloured brown, often with yellow shafts to the feathers. Beak as legs in both cock and hen. Comb, face, gills and deaf-ears as the cock, but scarcely so red, though quite red. Neck-hackle a rich reddish golden colour striped with dark stripes. Breast and thighs a reddish fawn colour, or reddish bay colour, tinged with salmon colour. Tail dark blackish brown. Legs, feet, &c., willow preferred for cup birds. The nails should be dark with willow legs.

For courage willow-legged birds are not the best of this

colour as a rule; the blackish, carp-brown, and the white-legged birds, when red-eyed, being of the highest courage.—
NEWMARKET.

FURTHER REMARKS ON THE JUDGING OF BUFF COCHINS.

ENCOURAGED by the favourable criticism of "NEMO" and "Y. B. A. Z.," I venture to supplement my former letters, in which I pointed out some anomalies in judging Buff Cochins, by a few additional remarks. First, let me say "one word" in reply to "Y. B. A. Z."

A Cochin pullet or hen, minus the few principal feathers of her tail, can scarcely be said entirely to lack that member. A case in point came under my immediate notice very recently. A pen of Cochins, in this apparently tail-less condition, was passed over without mention at an exhibition of poultry. About a week afterwards they were sent to another, but in the meanwhile a very minute tip of black had projected beyond their tail fluff. It was just visible, and only just, but it made all the difference, and the birds referred to at once obtained precedence over some of their successful rivals of the previous week.

Another case has come to my knowledge, where a pair of Cochin hens were excluded from the prize list because one of them was tail-less, and, the Judges concluded, was therefore trimmed. In this case the bird had moulted her tail later than the rest of her plumage, and the principal feathers had not made their appearance; but, as in the case before referred to, they were all there, and if the Judges had only taken the trouble to handle the bird, they could easily have convinced themselves that not a single feather had been abstracted.

If, then, it be possible for a judge in the great majority of instances to satisfy himself beyond reasonable doubt as to whether trimming has or has not been practised, it is plainly his duty not to disqualify till he has ascertained by actual investigation whether the phenomena are due to nature or art.

It may of course be objected that a bird in such a condition is not fully developed, and therefore ought not to be exhibited. I have before replied to this, that, if so, secretaries should no longer announce that the ages of the birds exhibited will be taken into consideration by the judges; but I will venture further to illustrate the case in point by a parallel instance. What judge ever yet disqualified a Cochin pullet for not having "put up" her comb? And yet what judge could say, with certainty, of any pullet to which he had given a prize while in such an undeveloped stage, that she would not within a few days develop a comb too large, or twisted, or falling over?

If, then, a bird lacking the principal feathers of her tail ought to be disqualified, so, too, ought a bird whose comb has not undergone that process of development which usually precedes laying.

I have mentioned this question of comb incidentally, and as illustrating another subject; but I am anxious to call attention to it on other grounds. Would any brother fancier enlighten me as to the cause of twisted and crooked combs in my favourite breed, Buff Cochins?

I have been very careful to breed, on both sides, only from birds with irreproachable combs—low, firm, straight, and evenly serrated; and yet the majority of my pullets are developing their combs, some twisted, some falling over, many more like that of a Dorking than a Cochin. So long as their combs remain in the chicken stage they can hold their own in competition; but as soon as ever the usual development takes place their value as exhibition birds is at an end. If any brother

amateur who has experienced this same difficulty would give me his advice on the subject I should feel grateful. Can it be due to diet or climate, or any preventible cause, or is it usual for straight-combed birds to be in the minority?

Of one fact I am very certain—that it is a mistake to send valuable pullets to a show which is lighted with gas before the comb has assumed its adult development. There can be no doubt that the heat of the gas draws up the comb with unnatural rapidity; so that, too weak to bear its own weight, it becomes twisted or falls over. I have seen many instances of this, and have heard of still more. I did not see the last Birmingham Show; but in that of the previous year there were cases both of prize and commended pullets, with, to say the least, suspicious combs, where the birds referred to could scarcely have occupied the position they did had their combs presented the same appearance to the Judges which they presented to the public during the later days of the Show.

In one of my former letters I ventured to criticise a judgment of one of our deservedly most esteemed poultry judges. It has only just come to my knowledge that the statement which I made at the close of my letter is entirely erroneous. It therefore becomes my duty to make the only reparation in my power to Mr. Hewitt, by offering to him my most sincere and heartfelt apologies for having made an unfounded charge calculated to give him so much annoyance. I am taking an opportunity of privately explaining to him at large how I was myself misled; but though he has expressed no wish whatever to me on the subject, I feel that I cannot do less than endeavour to make my acknowledgement of my mistake as public as the mistake itself.—DELTA.

THE GAME COCK'S TAIL.

"NEWMARKET" does not seem to recognise more than two styles of tail, which he designates the drooping and the upright, and he advocates an upright tail well fanned. There is another style of tail which many other breeders and exhibitors of Game fowls besides myself prefer, and that is the "whip" or "switch" tail, composed of shorter, narrower, and harder feathers than any other, and in the general opinion it is far more elegant, and more in keeping with the fine head and neck of a Game cock. Birds with the switch tails do not, when in health and condition, droop them, but carry them well back at a slight elevation; and from personal knowledge I can affirm that I have found such birds the quickest, hardest, and most enduring of any.

I very much prefer the close, tight, and narrow tail of a moderate length in a Game hen, to the open or fanned tail, however good and sound its feathers may be.

Another point which has struck me is that "NEWMARKET" condemns as "cross-bred," and "not pure enough for cup and prizetakers," all the Brown Red Game cocks with any black stripes in the breast, and all hens with black bodies and striped hackles, although he acknowledges these to be the favourite colours.

While reading these remarks I thought, Are we not, then, to endeavour to improve any breed, to cultivate any better or handsomer style of marking and colour, and are we to confine ourselves to the oldest style we can find? How would the Spanish of twenty years back look in competition with the birds of the present day, whose faces have received the most careful attention at the hands of their breeders? or how would the originals of several other breeds of poultry stand comparison with their more cultivated descendants?

Another point, and the last I would call attention to to-day, is the designating of the Black-breasted Red breed "Partridge" hens. We might with as much propriety call Duckwing hens "Partridge"-feathered, as Black-breasted Reds. The Dark Cochins are also frequently called "Partridge," but often "Grouse," which I think is far nearer the mark.—EXETER.

[There are both.—EDS.]

FOUR-TOED HOUDANS.

HOUDANS increase in favour day by day—a good article always speaks for itself, and such they prove themselves everywhere to be. One correspondent says many of his hens laid from 200 to 250 eggs last year; another that a Houdan is as good eating as a hen Pheasant; while everybody admires the total disregard they have for dirt, damp, and cold.

I want to alter one point—that is, to do away with that wretched fifth toe. Of course, every one wants five-toed birds,

because "our judges" say it is right; but let the question be well ventilated, and let it be understood that a well-matched pen of four-toed birds is quite as perfect as one of five-toed birds. Put in the thin end of the wedge first; put four-toed birds on an equality with five-toed birds, and the latter will gradually vanish. No man, I suppose, in his senses, will say that five toes are preferable to four toes, as the making of a foot. I take it that does not admit of an argument. As for saying that Houdans are only pure when five-toed, it is sheer nonsense. Numberless birds come four-toed, and many with four toes on one foot, and five toes on the other; and, moreover, four-toed birds breed five-toed, and the reverse; so there really is no rule. It is, however, certainly most provoking to see a fine bird in all points put on one side because he has four toes, which ought instead to be to his benefit.

I want to see Houdans perfect, and I am certain that with four toes only they will be less liable to feet diseases than they are now.—F. H. SCHRÖDER.

LIGHT AND DARK BRAHMA POOTRAS.

As an old breeder and exhibitor of Light Brahmas, I hope I may be allowed a word on the above point. Mr. Worthington and Mr. Pares, both very enthusiastic admirers of the Light birds, seem to me to forget that the committees of shows are not blessed with unlimited means for the bestowal of cups. On the contrary, in a great many cases the attempt to lay the foundation of a permanent show, especially amongst us southern, results in loss to the originators. Take Bristol and Clifton, for instance, with its liberal schedule, its beautiful show room, the wealthy inhabitants, and teeming population, still the result is a loss more or less pronounced. Under such circumstances it does seem too hard to expect that in lieu of a cup to the best pen of Brahmas, one should be offered to Light, and another to Dark. At this rate, why should not the different varieties of Cochins ask each for a cup? More pointedly still, why not the various breeds of Hamburgh? The differences between them are surely as marked as those existing between Light and Dark Brahmas.

At the great majority of shows Brahmas have been divided into Light and Dark. What an advance this is on the time when, some three or four years ago, I urged in our columns the claims of Brahmas generally to a class. Is it to be, that having obtained this class at every show worth the title, having even obtained the division of this class at many exhibitions, Dark or Light breeders are still to be dissatisfied? Mr. Worthington, and Mr. Pares, and the Light breeders say, that it is all very well, but the Dark birds always take the cups. My reply is, Do they not always deserve them? I have but few opportunities of seeing shows; but wherever I do go, I am struck by the degeneration of the Light birds, while it must be allowed by all that the Dark have improved. This opinion must go for just what it is worth, but it is my honest opinion, written with no unkind feeling towards my old love. In the mere matter of leg-feathering, how infinitely inferior are the Light birds generally to the Dark. In the matter of legguiness, again, I think all will allow that generally the Dark class shows less of this failing. I recollect well a gentleman writing to me for Light birds some years ago, in which letter he said he had once asked Mr. Hewitt whether if two birds were equally good, he would give the prize to the Light. His reply was, Yes; but he had never seen the Light bird that was equally good. With this verdict from Mr. Hewitt, in the palmy days of the Light birds, when Mr. Pares's old cock was alive, what is to be expected now, when, as Mr. Pares says himself, he has never seen his equal since?

I cannot at all agree with the plan on which the decision of a cup should rest, according to Mr. Pares—viz., "The best relatively of its own variety." Does not this proposition carry on the face of it an admission that the Light birds are generally inferior to the Dark? What is the difference between the Light and Dark birds? Ought there to be any other difference than that of colour? Geese and Ducks are two distinct breeds; a cup given to these might be decided on the "relative" merits, one between two varieties of the same breed on the "comparative" merits.

So far as I can see, the Light birds are beaten by the Dark in size, substance, depth of breast, length of leg, and leg-feathering; at least, as the generality of each variety are exhibited at the present day. Will my Light Brahma friends feel hurt if I endeavour to reply to the question, Why is there this

inferiority? My old Light Brahmas, fourteen years ago, came from Garbanati's challenge birds. The pair of hens must have weighed 19 lbs. to 20 lbs., the smaller I showed at Newport weighing over 10 lbs., the other was a larger-framed bird; but on the score of colour they were vastly behind the present Light birds. Both cock and hens were darker, the white colour far less clear. At the present day, you may run over pen after pen of Light birds, and in colour they are perfect as to whiteness—often the hackle is too light. The rage has been to breed for colour, to discard birds however good, if the plumage is at all spotted with black. This has been carried out in some degree in the Dark variety, but there less damage has resulted; but to the Light birds, as I see them, it has proved ruinous, more or less, to all those points that should mark a good Dark or Light Brahma. It is possible that the two colours, and the other points, may hereafter be found united. Whenever that does takes place, I prophesy that the cup for the best pen of Brahmas will be found awarded to Light birds. Even now they are beautiful, then they would be amongst the very handsomest of our domestic poultry.—Y. B. A. Z.

I AM pleased to find the position of Light Brahmas in the prize lists being discussed in "our Journal," and have purposely waited the result of the Somerset County Show before offering my opinion upon the truths contained in Mr. Worthington's letter of the 19th of December, which is so much strengthened by the able communications from Mr. Pares and Mr. Crowley in the Journal of the 2nd inst.

It is, undoubtedly, true that the Light Brahmas have oftentimes been most grievously wronged at poultry shows, where cups have been awarded to Dark Brahmas of a most inferior description, when really first-class Light Brahmas have been shown against them.

In some instances that have come under my own notice, the judges have, on the other hand, been annoyed at not having the power to award the cups to perfect pens of Light Brahmas, instead of giving them to second-rate Dark Brahmas, because of the prize schedule announcing cups for Dark Brahmas only.

With regard to the general merits of both Dark and Light Brahmas, and their individual beauty, I think there can be no doubt but that the prevailing opinion will be found in favour of the Light Brahmas, as to the latter point; as to size, shape, laying qualities, and as fowls for table use, Light and Dark are equal at present, although I most firmly believe that as the Rouen Ducks have surpassed the Aylesbury in weight and general excellence, so will the Light Brahmas beat the Dark.

With regard to any difficulty judges may have in deciding as to which should win the cup of those two varieties, I will at present take the Somerset County Show as an example, upon which I have some of the best opinions, that the cup should have gone to the Light Brahmas, as the winning Dark were by no means superexcellent.

May we, the exhibitors of this most valuable and beautiful variety of fowl, hope you will use your powerful influence in our behalf? Place them upon an equal footing with their Dark relations, give them separate cups to win, and judge them impartially, and we have no fear as to which will come to the front.—F. CROOK.

As a friend of the Light Brahmas, I trust you will permit me to corroborate what has been lately written in your columns respecting the dissatisfaction which exists at the custom of combining Light and Dark in competition for the cup at poultry shows.

The custom is likely to be injurious in more ways than one. It must render the duties of the judges more difficult and onerous; for if it is notoriously often difficult to avoid giving dissatisfaction in judging birds of the same class, how much more difficult must be the judging of birds of different classes? Better, surely, to offer no cup than to offer it on conditions that foster discontent.

Then, as regards the exhibitors. They are forced to compete with birds of a different class from their own, which many will consider unsatisfactory, whether they win or lose; and they have the additional annoyance of knowing that, as the cup is nearly always adjudged to their rivals, their chance of success is almost hopeless.—R. HARVEY, Southampton.

It gives me much pleasure to observe that the friends of the Light Brahmas have at length determined to make a stand against the treatment their beautiful pets are and have been

receiving at the hands of the judges. It is quite preposterous that Dark Brahmas, merely because they are Dark, must beat all Light, no matter how great their merit. I find it useless to send Light to exhibit in a class for both varieties, as "Brahmas, any variety;" for Dark, even when relatively inferior, sweep off all the prizes. I trust that this state of things will not continue, but that there will be in every show a class for each variety; also, that when competing for a cup and medal, the Light will be put on an equal footing with the Dark.—ALEXANDER W. SHAW, *Lincolnton*.

TRIMMING SPANISH FOWLS' FACES.

I AM not a disappointed caviller, though, if honesty is the ruling principle, I am, I think, a hardly-used exhibitor. I know all the complaints made against judges, &c., to whom, I think, great praise is after all due; but I have never heeded them, taking them to be, as in part, perhaps, they are, simply the complaints of the discontented. Whether this my letter is the same I leave you to decide.

Now, I ask any disinterested person to take one class of fowls—viz., Spanish, and examine critically the faces of the birds at any show, and then to give me a candid answer whether in his opinion the faces of any, and generally the prizetakers, are trimmed or not? Again, I ask, supposing the answer in the affirmative, is this honest? If it is honest, let it be understood that it is so, that all may have the advantage (and a great one it is), of sending their birds trimmed; but if it is not honest, let it be held as such, and condemned accordingly. That it improves the bird's appearance no one, I think, can doubt; and I say nothing as to whether birds should be sent as they are, or as they ought to be; whether they should be the real or the ideal; but let all the honest and (I will not say dishonest) "those who see no harm in it," have the same advantages.

I do not think the exhibitors are alone to blame; I strongly blame also the judges. For if they do not, they ought to know, when to distinguish a natural from a non-natural face. I maintain that they, by not condemning this practice, virtually encourage, and, therefore, are themselves sharers in it.

Again, not only is it dishonest in these individuals, but also, I maintain, that the managers of the shows are to all intents and purposes obtaining money under false pretences. If I send my bird untrimmed, but in every respect good, I expect him to have as good a chance as one that is trimmed—nay, I should say, even a better; but it has not as things exist at present, and, therefore, I pay my money under a false impression. If, however, it is a recognised principle that all may do so, I have done; my point is gained. I do not myself see, in fact, why it should not be so.

Of course, some one will exclaim, "Oh! here is a maundering complaint of one who sends bad birds and expects prizes." Perhaps it is so; but that is not the question. I ask him to judge for himself. As it happens, I have a somewhat substantial proof that it is done, and that accordingly the judges wink at it, and so the more tender-conscienced suffer. Of course this is supposing the judges are competent persons (and their names ought to be sufficient guarantees for this); if they feel they are not, they have no business to judge. To one who knows anything about the matter at all, such things ought to be clear.

I shall suggest no remedy, it is simple enough, and shall say no more, but leave it in the hands of those more competent than myself to judge. One thing I ask. Let it be strongly decided either that all may trim or none, though this latter is nominally the rule even now; and let also the judges, who have it in their power, enforce honesty, remembering that if deceit is practised in one class it is probably done in another. It is as dishonest, under existing circumstances, to pick feathers from a Spanish fowl's face as from a Brahma's hock. Do not let poultry-fanciers be the contradicators of the apparently somewhat selfish motto, "Honesty is the best policy."—A. H. D.

POULTRY ACCOUNT FOR THE YEAR 1867.

BREED—Pure Dorkings, and cross-bred Brahma and Dorkings. No. of eggs, 1561. Chickens hatched, 157. Chickens reared, 124. Average No. of hens, 24. Out of 124 chickens reared, 52 were destroyed by rats and dogs, and during the cold and humid months of October, November, and December, my

fowls ceased to lay altogether; however, my balance sheet will stand thus:—

	£	s.	d.
139 dozen of eggs at 1s. per dozen	13	10	0
52 Cockerels and Pullets killed for the house, at 2s. each	5	4	0
6 Pullets sold at 3s. each	0	18	0
20 selected Pullets and Cockerels remaining in stock, at 6s. each	6	0	0
Cost of corn at one bushel per week	18	12	0
Profit	8	4	0

I have charged the house with eggs at 1s. per dozen, for which I could have readily obtained much more had they been sold; and many of the chickens killed would have realised 5s. or 6s. per pair.—Powis, *Liverpool*.

MY POULTRY YARD.—No. 3.

With my French fowls I was successful. I began by purchasing a sitting of eggs; but at first my hopes were doomed to be frustrated—not an egg hatched. I next procured another sitting from the same vendor, and hatched two birds; I then bought one more dozen, and hatched four: so altogether I had six Crève-Cœurs. The chickens all lived and did well. There were four hens and two cocks. I saved the most promising of the cocks, and then with a cock and four hens started again.

My hens were all black, and so was the cock till six months old, when gradually silvery white feathers appeared in the hackles, and they went on increasing till the cock had a silver collar. He was a very handsome bold-looking bird with a fine crest and comb, and the hens were good birds too. They commenced laying in December, and laid in the twelve months 643 eggs—namely, December, 15; January, 68; February, 87; March, 82; April, 49; May, 57; June, 88; July, 81; August, 62; September, 45; October, 7; November, 2.

I sat many of these eggs, and hatched good chickens, which did well for the table in spite of their blue legs. My hens never showed the least inclination to sit, but after stopping laying eleven or twelve days began again. They laid good-sized white eggs with yolks of a pale yellow colour. I did not think the eggs quite as richly flavoured as those of the Hamburgs and other breeds, but they laid well. They bore confinement well, though rather spiteful birds. They had the fault of their crests getting wet by the early dews, the feathers then massing together and falling down on either side, disclosing the flesh. When they did this I used to comb their crest feathers, and they would then recover their proper posture in a few hours.

I eventually gave up this breed, because the cock died and I could not obtain another easily; and then I took to Dark Brahmans—that most perfect kind of fowls—that breed which will supply you with eggs when other fowls are cut up by the cold. They are truly hardy, useful, clean fowls.—R. S. S. W.

KENDAL POULTRY SHOW.

THE thirteenth annual Exhibition was held in Albert Buildings, Kendal, on the 16th, 17th, and 18th inst. There were upwards of 700 entries. The following is the list of awards:—

GAME (Whites and Piles).—First, E. Pashley, Workshop. Second, R. Butcher, Chesterfield. Third, J. Brough, Carlisle. Highly Commended, J. Philipson, Lyth, Milnthorpe; A. Dawson, Kendal.

GAME (Black-breasted and other Reds).—First, Duke of Newcastle, Cumber. Second, W. J. Cope, Barnsley. Third, T. Robinson, Ulverston. Highly Commended, J. Fletcher, Stoneclough; C. W. Brierley, Middleton, Manchester; J. Wood, Wigan; A. Dawson. Commended, E. Akroyd, Bradford; J. H. Wilson, St. Eves. **Chickens.**—First and Cup, Duke of Newcastle. Second, T. Burgess, Burleydam, Whitechurch. Third, A. K. Briggs, Bradford. Highly Commended, J. Hodgson, Whittington, Burton; J. H. Wilson. Commended, T. Mason, Green Ayre, Lancaster; D. Tait, Hawkshead.

GAME (Any other variety).—First, W. J. Cope. Second, Duke of Newcastle. Third, J. Fletcher. Highly Commended, J. Wilson, Penrith. Commended, W. Pooley, Beathwaite Green, near Milnthorpe. **Hens.**—First, C. W. Brierley. Second, W. Hodgson, Darlington. Third, J. C. Bell, Kendal. Highly Commended, J. Larrow, Kendal; E. Aykroyd, Bradford; T. Robinson.

HAMBURGERS (Silver-spangled).—First and Third, H. Beldon, Goitstock. Second, J. Fielding, Newchurch, near Manchester. Highly Commended, J. Fielding; J. Smalley, Livesey; H. Pickles, jun., Early. Commended, J. Robinson, Garstang; J. Wild, Waterworks House, Ashton-under-Lyne; T. C. & E. Newbitt, Epworth.

HAMBURGERS (Golden-spangled).—First and Cup, H. Pickles. Second, H. Beldon. Third, J. Walker, Knarborough. Highly Commended, E. Brierley, Heywood; T. Burgess, H. Beldon. Commended, T. Stuart, Staveley, Kendal; A. A. Hyde, Hurst, Ashton-under-Lyne; J. Mann, Staveley, near Manchester; N. Maplow, Denton, near Manchester.

HAMBURGERS (Silver-pencilled).—First and Cup, H. Beldon. Second, J. Walker. Third, H. Beldon. Highly Commended, J. Preston, Allerton,

near Bradford; J. Smith, Earby. Commended, W. & J. Bairstow, Ferncliffe, Bingley.

HAMBURGERS (Golden-pencilled).—First and Second, H. Beldon. Third, W. Parr, Patricroft. Highly Commended, B. Bee, Bullsnap; J. Robinson; W. Bowe, Carlisle; T. D. Mort, Stafford; H. Pickles. Commended, J. R. Jessop, Hull; F. Pittis, jun., Newport, Isle of Wight.

DORKINGS (Coloured).—First, J. Robinson. Second, J. Clift, Dorking. Third, J. White, Warlaby. Highly Commended, J. Cople, Ecclestone, Prescott; D. Parsons, Cuddon. Commended, Duke of Newcastle. **Chickens.**—First and Cup, J. Cople. Second, W. Rutledge, Storthend. Third, Duke of Newcastle. Highly Commended, J. Robinson; J. Clift. Commended, D. Gellatly, Meikle; G. Roadley, Wetherall Abbey, Carlisle.

DORKINGS (Silver-Grey).—First, R. D. Holt, Orrest Head. Second and Third, R. Smalley, Lancaster. Commended, W. Rutledge. **COCHIN-CHINA (Cinnamon and Buff).**—First and Cup, C. W. Brierley. Second, Hon. Miss Douglas Pennant, Penrith Castle, Bangor. Third, T. Stretch, Ormskirk. Highly Commended, H. Beldon; J. Mapplebeck, Mosley; Messrs. Gunson & Jefferson, Whitehaven.

COCHIN-CHINA (Brown and Partridge-feathered).—First, T. Stretch. Second, E. A. Aglionby, Estwaite Lodge, Hawkhead. Third, C. W. Brierley.

COCHIN-CHINA (White).—First and Second, R. Smalley. Third, R. Chase, Balsall Heath, Birmingham. Commended, S. Sherwon, Whitehaven. **Chickens.**—First, Second, Third, and Highly Commended, R. Smalley. Commended, J. W. Carter, Preston.

SPANISH (Black).—First, H. Beldon. Second, Dorch & Bonlter, Sheffield. Third, J. Thresh, Bradford. Commended, A. Fulton, Sedgwick.

Chickens.—First and Cup, H. Beldon. Second, Messrs. Bowman and Fearon. Third, J. Newton, Silsden, Leeds. Highly Commended, Messrs. E. & H. Cumber, Warrington; R. Brown, Stockport; J. H. Wilson; Hon. Miss Douglas Pennant.

BRAHMA POOTRAS (Light).—First, H. Lacy, Lacy House, Hebden Bridge. Second and Third, J. Pares, Postford, Guildford.

BRAHMA POOTRAS (Dark).—First and Cup, W. Hargreaves, Bacup. Second, H. Lacy. Third, Hon. Miss Douglas Pennant. Highly Commended, Miss E. A. Aglionby; Rev. H. Monsarrat, Kendal.

FRENCH.—First, Col. Stuart Wortley, Grove End Road, London. Second, H. Beldon. Third, R. Brown, Cheadle, Hulme.

ANY OTHER DISTINCT VARIETY NOT PREVIOUSLY MENTIONED, EXCEPT RASTAMS.—First, H. Beldon. Second, W. Mason, Denton, Manchester.

Third, S. Taylor, Ibbotsliedme. Highly Commended, G. Hustler, Stillingfleet; W. Robinson, Garstang; D. Parsons; J. R. Jessop; F. Pittis, jun.

SELLING CLASS (Any variety).—First, H. Beldon. Second, N. Cook, Chawthorn. Third, J. Thompson, Bingley. Highly Commended, J. Walker, Kendal; T. Taylor. Commended, J. Walker; J. Wilson, Penrith.

GAME COCK.—First, C. W. Brierley. Second, J. Fletcher. Third, W. Boulton. Fourth, E. Akroyd, Bradford. Highly Commended, Capt. Wetherall, Loddington; W. Boyes, Beverley. Commended, J. Fletcher.

Cockerel.—First and Cup, B. Jarvis, Mansfield. Second, R. Pashley. Third, J. Fletcher. Fourth, W. J. Cope, Barnsley. Highly Commended, W. Boulton. Commended, R. B. Riley, (Oven), Halifax.

ANY OTHER VARIETY EXCEPT GAME AND RASTAMS.—(Cock).—First, Mrs. Moffat, Ecclefechan. Second, H. Beldon. Third, Hon. Miss Douglas Pennant. Highly Commended, A. Fulton, Sedgwick.

BANTAMS.—First, J. Wood, Chorley. Second, C. W. Brierley. Third, J. Buckley, Melton Mowbray. Highly Commended, Rev. A. K. Cornwall, Bencombe; Messrs. Furness & Bamber, Wood Nook, Accrington; Messrs. W. & H. Buckley, Accrington.

GAME (Black-breasted and other Reds).—First and Cup, J. Parlett, Huntington. Second, Mrs. Dale, Scarborough. Third, J. Buckley. Highly Commended, W. Boulton; F. Powell, Knarborough; Messrs. Bowman & Fearon.

GAME (Any other variety).—First, E. Jarvis. Second, R. Swift, Southwell. Third, J. Parlett. Highly Commended, J. R. Robinson; H. Shumack, Southwell; F. Pashley.

BANTAMS (Any other variety).—First, W. J. Cope, Barnsley. Second, Messrs. Tonkin & Tucker, Bristol. Third, C. W. Brierley. Highly Commended, A. K. Eriger, Bradford.

DUCKS (White Aylesbury).—First and Cup, Mrs. M. Seamus, Hartwell, Aylesbury. Second, E. Leech, Rochdale. Third, Mrs. M. Seamus. Highly Commended, Rev. G. Hustler; D. Hardie, Langholm.

DUCKS (Rouen).—First, W. Willison, Highgate. Second, Rev. G. Hustler. Third, D. Hardie. Highly Commended, E. Leech; T. Noble, Natland Park; J. Robinson. Commended, A. Stuart, Staveley, Kendal; J. White, Whitley Netherthorn, near Wakefield; T. Robinson.

DUCKS (Any other variety).—First, S. & R. Ashton, Mottram. Second, E. Longton, Woolton. Third, D. Parsons. Highly Commended, Messrs. J. B. & R. E. Cockerton, Cartmel Fell. Commended, Mrs. T. W. Simm, Watercrock, Kendal.

PIGEONS.

CARRIER.—First, J. Hawley, Bingley. Second, W. Jackson, Bolton-le-Sands. Commended, J. Cragg, Kendal.

TUMBLERS (Almond).—First, E. Brown, Sheffield. Second, F. Key, Beverly. Highly Commended, J. Fielding, jun., Rochdale. Commended, R. Whitaker, Bolton; J. Fielding, jun.; Messrs. T. C. & E. Newbitt, Epworth.

TUMBLERS (Any variety).—First, R. Whitaker. Second, J. Fielding, jun. Highly Commended, J. Fielding, jun.; T. Newell, Ashton-under-Lyne; J. Hawley. Commended, H. Yardley, Birmingham.

OWLS.—First and Second, J. Fielding. Highly Commended, T. Newell; J. Towerson, Egrement. Commended, Messrs. T. C. & E. Newbitt.

POUTERS AND CROPPERS.—First, T. Kew, Burton, Westmorland. Second, H. Yardley. Highly Commended, J. Hawley. Commended, J. Towerson.

BARBS.—First, T. Kew. Second, R. Thompson, Moresdale Hall. Highly Commended, H. Yardley.

BANTAMS.—First, J. Hawley. Second, Messrs. T. C. & E. Newbitt. Commended, Mrs. Arnold, Aldrigg End.

TERRITS.—First, J. Hawley. Second, T. Rutherford, Thirsk. Commended, J. Fielding.

TRUMPETERS.—First, J. Thompson, Bingley. Second, J. Hawley. Highly Commended, J. Hawley; J. J. Wilson, Darlington.

JACOBS.—First, Second, and Highly Commended, R. Thompson. Commended, T. Newell; J. Thompson; J. Towerson.

ANY OTHER VARIETY.—First, R. Thompson. Second, H. Yardley. Highly Commended, H. Yardley; J. Rutherford. Commended, J. Hawley.

SELLING CLASS.—First, Messrs. T. C. & E. Newbitt. Second, J. Thompson. Highly Commended, W. Jackson; F. Key.

LOCAL CLASSES.

GAME (Any variety).—*Chickens*.—First, M. Graham, Kendal. Second, J. Barrow, Kendal. Third, G. Robinson, Highgate, Kendal. Highly Commended, M. Graham.

GAME (Any variety).—*Hens*.—First, R. Woolf, Old Hutton. Second, J. Barrow. Third, R. Mattinson, Kendal. Highly Commended, J. Gelderd, Kendal; M. Graham.

HAMBURGERS (Any variety).—*Chickens*.—First, W. M. Mann, Kendal. Second, S. Noble. Third, T. J. Harrison, Singleton Park. Highly Commended, T. Smart; W. Mann. Commended, J. Hutchinson, Kendal.

SPANISH (Black).—*Chickens*.—First and Third, J. Goth, Woodside. Second, J. P. Harrison, Kendal. Highly Commended, J. Bateman, Kendal.

DONKINGS (Any variety).—*Chickens*.—First and Highly Commended, R. D. Holt. Second, W. Rattledge, Kendal. Third, P. Wilson, Kendal.

BANTAMS (Any variety).—*Chickens*.—First and Second, J. Gelderd. Third, W. Caton, Kirkby Lonsdale.

DUCKINGS (Any variety).—First, J. Goth. Second and Third, R. Willson. Highly Commended, A. Smart. Commended, R. W. Simpson, Kendal.

TURKEYS.—First and Third, T. J. Harrison. Second, C. W. Wilson, Oxenholm.

GEES.—First and Third, T. J. Harrison. Second, R. Rawlinson, Kendal. Highly Commended, C. W. Wilson; C. Elenkorn, Whitwell.

BARNDOR (Cross-bred).—First, T. Bradley. Second, J. Harrison, Burnside. Third, J. Cragg.

JUDGES.—Mr. T. Challoner, Chesterfield; Mr. Sargenson, Liverpool; and Mr. R. Tebbay, Fullwood, Preston.

NENTHEAD POULTRY AND CANARY SHOW.

The third annual Show took place in the village schoolroom at Nenthead, Cumberland, on the 17th inst.

The prizes were not such as to encourage competitors from a distance, but many of the pens shown were very creditable to the local exhibitors, especially the *Game*, which seem to be general favourites, some of the pens and many unmatched birds being of great merit. The pen of adult birds shown by Millican & Brown were fine birds in the hand, though the cock had suffered the loss of most of his tail. Messrs. Walton & Rutherford's pen of Black-breasted Red chickens could not be easily beaten at any show.

Golden-spangled *Hamburghs* were very poor, but the Silver-spangled were better. Many good pens of both Gold and Silver-pencilled were shown. In fact these birds far excelled the Spangled in point of merit.

Dorkings were few but good. In *Bantams*, Gamewon both in the adult and young class. The first-prize pen of chickens was of unusual merit. Some very good *Cochins* were also exhibited.

In the class for hens a fine pair of *Game* was first, and an excellent pair of Spanish second.

Ducks and *Pigeons* did not muster well, for unfortunately the deleterious quality of the water from the lead mines, and the quantity of poisonous matter on the roads, prevent their being kept in any numbers.

The show of cage birds was large and well worth seeing. Canaries, especially, receive much attention in the neighbourhood.

A most perfect pair of Himalayan Rabbits was first, and two Lop-eared of dissimilar colours were second. The clergyman of the village is President of the Society, takes great interest therein, and can bear testimony to its beneficial influences in a moral as well as pecuniary point of view.

The following is the prize list:—

GAME (Black-breasted and other Reds).—First, Millican & Brown, Nenthead. Second, W. Walton, Cocklake. Highly Commended, Walton and Rutherford, Greenheads. *Chickens*.—First, Walton & Rutherford. Second, J. Stephenson, Nenthead. Highly Commended, W. Laverick, Nenthead.

GAME (Any other variety).—First, Millican & Brown. Second, J. Gibson. *Chickens*.—First, W. Walton. Second, Millican & Brown.

HAMBURGH (Golden-spangled).—First, R. Pickering, Frosterly. Second, T. Horne. *Chickens*.—First, R. Pickering. Second, T. Horne.

HAMBURGH (Golden-pencilled).—First, J. Stephenson. Second, Millican & Brown. *Cockerel*.—First, J. Stephenson. Second, Walton and Rutherford.

HAMBURGH (Silver-spangled).—First, E. Hudspeth, jun. Second, Walton & Rutherford. *Chickens*.—First, J. Taylor, Frosterly. Second, Walton & Rutherford. Highly Commended, W. Graham, Prynouse.

HAMBURGH (Silver-pencilled).—First, M. Ridley. Second, J. Stephenson. *Chickens*.—First, J. Taylor. Second, M. Ridley.

DORKINGS (Any colour).—First, M. Ridley. Second, J. Walton, Galligill. *Chickens*.—First, Walton & Rutherford. Second, J. Percival.

SPANISH.—First and Second, T. Storey. Commended, I. Walton.

POLANDS.—Second, Wilkinson & Henderson.

BANTAMS.—First, T. Horne. Second, F. Clementson. *Chickens*.—First, Millican & Brown. Second, J. Gibson.

COCHIN-CHINA.—First, J. Dryden. Second, T. W. Dickinson. Commended, J. Pickering; J. Dryden.

DECKS.—First, Kirsopp. Second, I. Walton.

ANY VARIETY.—*Hens*.—First, Millican & Brown. Second, Wilkinson and Henderson. Highly Commended, Millican & Brown; T. Brown.

PIGEONS.—First, W. Graham. Second, R. Walton.

CANARIES.—*Belgian*.—First, J. Douglas, Stanhope. Second, J. Nicholson, Alston. *Norwich*.—First, R. Milburn, Tow Law. Second, J. Douglas.

LIZARD (Any other variety).—First and Second, J. Douglas. *Common (Yellow)*.—First, B. Dryden, Nenthead. Second, J. Nicholson. *Common (Buff)*.—First, J. Hind, Nenthead. Second, T. Wilkinson. *Common (Yellow)*.—First, T. Wilkinson. Second, W. Thompson, Nenthead. *Common (Green)*.—First, R. Milburn. Second, T. Wilkinson. *Common (Cinnamon)*.—

—First and Second, J. Stephenson. Highly Commended, J. Douglas. *Common*.—First, T. Wilkinson. Second, W. Thompson.

GOLDFISH.—First, G. Hopkins, Nenthead. Second, R. Milburn.

BULLFINCH.—First and Second, W. Hetherington, Nenthead.

MOLE (Nearest a Canary).—First, R. Milburn. Second, W. Hodgkinson, Nenthead.

EXTRA PRIZES.—First, T. W. Dickinson. Second and Highly Commended, J. Stephenson.

The Judge was Mr. E. Hutton, of Pudsey, Leeds.

NEWARK POULTRY SHOW.

The Newark Poultry Society's first Show was held in the Corn Exchange on the 16th and 17th inst., when upwards of 400 pens of Poultry and 200 of Pigeons were shown. The *Spanish*, *Dorkings*, *Cochin-Chinas*, and *Beahna Pouter* were all very good. *Game* were also very superior, especially those in the class for Black-breasted and other Reds. Of *Hamburghs* the Golden-spangled were poor in quality, but the Silver-spangled were good. Of the *Silvers* the entries were few, but there were some good pens among the Silver. The *Houdans* were good, and the first-prize pen one of the best we have seen. Of *Game Bantams* there was a brilliant gathering, and the first-prize pen of *Silberights* was beautifully laced. The White and Black *Bantams* were good, especially the first-prize pen of Blacks.

The *Tucks* were good, but the *Rouens* as a class surpassed the *Aylesbarys*. *Turkeys* were very good, but *Geese* few, and nothing superior.

Of all the varieties of *Pigeons* there were very superior birds exhibited. It was on the whole a most excellent Show, and great praise is due to Mr. H. Tomlinson, the Hon. Secretary, for his exertions, to which the success is greatly attributable.

SPANISH (Black).—First and Second, F. James, Peckham Rye. Third, J. Walker, Newark. Highly Commended, J. R. Rodbard, Winton, Bristol. Commended, Messrs. Birch & Boulter, Sheffield; Hon. Miss Douglas Pennant, Penrhyn Castle, Bannor.

DORKINGS (Any colour).—First, Duke of Newcastle, Chamber. Second, H. Lingwood, Barking, Needham Market. Third, G. Clarke, Long Sutton. Highly Commended, H. Savile, Ollerton, Notts. Commended, O. E. Cresswell; J. Smith; J. Elgar, Osamthorpe Hall, Newark.

COCHIN-CHINA (Buff or Cinnamon).—First, H. Juppelbeck, Moseley, Birmingham. Second, R. White, Sheffield. Third, Duke of Newcastle. Highly Commended, Col. Stuart Wortley, Grove End Road, London; G. A. Crowe, Etwell, Derby; A. P. Burnell, Southwell.

COCHIN-CHINA (Any other variety).—First, T. M. Derry, Galley. Second, J. F. Lowerside. Highly Commended, J. Staley, Collingham, Newark; F. D. Johnson, Birmingham; R. White.

BANTAM (Any colour).—First, Miss A. Hart, Alderwasley, Derby. Extra First, H. Lucy, Heblen Bridge. Second, R. W. Boyle, Galtmire House, Bray, Co. Wicklow. Highly Commended, H. Lucy; M. A. Dixon, Cotgrave; W. Pares, Oakbrook, Derby; W. O. Quibell, Newark.

GAME (Black-breasted and other Reds).—First, Duke of Newcastle. Extra First, E. Jarvis, Mansfield. Second, Rev. W. J. Mellor, Clwrick Rectory. Highly Commended, Rev. W. J. Mellor; R. Swift, Southwell.

GAME (Any other variety).—First, R. Swift. Second, R. Pashley, Workson. Highly Commended, W. H. Wheeler, Carlton, Notts. Commended, Rev. W. J. Mellor; Miss E. Crawford, Farusfield, Southwell.

HAMBURGH (Gold-spangled).—First, J. White, Whitley, near Wakefield. Second, S. & R. Ashton, Mottram. Commended, H. E. Emberlin, Oadby.

HAMBURGH (Silver-spangled).—First, H. Pickies, jun., Easby. Second, S. & R. Ashton.

HAMBURGH (Gold-pencilled).—First, R. J. Boulton. Second, W. H. Tomlinson.

HAMBURGH (Silver-pencilled).—First, E. Comber, Warrington. Second, J. W. George, Beeston Podge. Third, Duke of Newcastle, Chamber.

CHIEF-COCHIN (Any colour).—First, Col. Stuart Wortley. Second, Hon. H. W. Fitzwilliam, Wentworth Woodhouse. Third, National Poultry Company.

LA FLÈCHE (Any colour).—First, National Poultry Company. Second, Col. Stuart Wortley.

HOUDANS (Any colour).—First, W. O. Quibell. National Poultry Co. Third, J. Elgar.

GAME BANTAMS (Any variety).—First, J. Crossland, jun., Wakefield. Extra First, R. Swift. Second, Rev. E. C. Tiddeman, Childerditch Vicarage. Highly Commended, E. Toder, Little Carlton, Newark; Rev. W. J. Mellor; E. Crawford; G. Heafford, Loughborough; W. Parker, Clay Cross; E. Bullimore, Foston.

BANTAMS (Gold or Silver-laced).—First, W. H. Tomlinson. Second, H. Draycott, Humberstone. Highly Commended, J. Smith; T. Davies, Newport, Mon.

BANTAMS (White, Clean-legged).—First, Rev. F. Tearle, Newmarket. Second, Rev. O. E. Cresswell, Haworth. Highly Commended, J. R. Jessop, Hull; S. & R. Ashton.

BANTAMS (Black, Clean-legged).—First, W. H. Tomlinson. Second, J. H. Bradwell, Southwell. Third, H. M. Maynard, Ryde, Isle of Wight. Highly Commended, H. Draycott; W. H. Tomlinson.

ANY VARIETY.—*Cock*.—First, Miss E. Crawford. Second, H. Savile. Third, National Poultry Company. Highly Commended, Hon. Miss Douglas Pennant; R. Pashley; T. Baker, Leicester; Mrs. E. Cross, Appleby Vicarage, Briggs; M. A. Dixon; P. Middleton, Newark.

DECKS (Rouen).—First, M. A. Dixon. Second, J. White. Highly Commended, J. W. Harrison, Spalding.

DECKS (Aylesbury).—First, J. W. Harrison. Second, J. Hornsby, Grantham. Highly Commended, Rev. G. Hadley; W. Pares.

GEES (Any variety).—First, R. Bentley. Second, Rev. G. Huxter. Highly Commended, R. E. Toder; National Poultry Company; H. Savile; T. Honker, Penridge.

TURKEYS (Any variety).—First, Rev. W. J. Mellor, Clwrick Rectory. Second, W. Sanday, Holme, Pierpoint. Third, J. H. Braikenridge, Chew Magna. Highly Commended, Miss C. Fillingham, Newark.

SELLING CLASS.—First, Hon. Miss Douglas Pennant. Second, Rev. J. Chapman, Elkesley Vicarage. Third, T. Rogers, Walsall. Fourth, R. Swift. Highly Commended, R. E. Toder; National Poultry Company; Hon. Miss Douglas Pennant; Duke of Newcastle; R. Pashley; H. Marshall, Cropwell Butler; J. J. Berry, Sheffield; J. Johnson, Newark; Lieut-Col. Eyre, Newark; H. Savile; A. H. Verity; J. Marchant, Halifax; W. O. Quibell; W. H. Tomlinson.

PIGEONS.

CARRIERS.—*Cocks.*—First and Second, F. Crossley, Elland. Commended, J. Deakin, Sheffield. *Hens.*—First, J. Hawley, Bingley. Second, H. Headly, Leicester. Highly Commended, F. Crossley.

POUTERS.—*Cocks.*—First, F. Crossley. Second, C. Bulpin, Bridgewater. Highly Commended, H. Draycott; J. Jaylor. Commended, J. Hawley.

Hens.—First and Second, F. Crossley. Highly Commended, J. Hawley.

TUMBLERS (Almond).—First, F. Crossley. Second, J. Hawley. Highly Commended, C. Martin, Chorlton Grove, Manchester.

TUMBLERS (Any other variety).—First, F. Crossley. Second, J. Hawley. Highly Commended, J. W. Edge.

BEARDS.—First and Second, W. H. C. Oates.

BARBS.—First, Rev. W. J. Mellor. Second, T. Hives. Highly Commended, Rev. W. J. Mellor; F. Crossley.

JACOBIANS.—First, W. H. C. Oates. Second, C. Bulpin. Highly Commended, F. Sales. Commended, J. Hawley.

OWLS.—First, F. Crossley. Second, J. Fielding, jun. Highly Commended, T. Hives; J. Fielding, jun.; H. Yardley; F. Crossley; R. Siddall; F. Sale.

TRUMPETERS (White).—First and Second, W. H. C. Oates. Highly Commended, F. Elze; C. Bulpin; W. H. C. Oates. Commended, J. Hawley.

TRUMPETERS (Any other variety).—First, Rev. W. J. Mellor. Second, C. Bulpin.

FANTAILS.—First, J. Hawley. Second, J. W. Edge. Third, C. Bulpin. Highly Commended, C. Bulpin; H. E. Emberlin.

TURBITS.—First, H. Mapplebeck. Second, J. Thompson. Highly Commended, C. Bulpin.

ANY NEW OR DISTINCT VARIETY.—First, H. Draycott. Extra First, National Poultry Company. Second, J. E. Hodges. Highly Commended, H. Draycott; J. Hawley; H. Yardley; C. Bulpin; F. H. Paget; W. H. C. Oates.

WINNER OF MOST POINTS.—Cup, F. Crossley, Elland, Halifax.

SELLING CLASS.—First, J. Hawley. Second, S. & R. Ashton. Commended, J. W. Edge; C. Bulpin; T. C. Marshall; J. Taylor; C. Martin; F. H. Paget; J. Walker.

JUDGES.—Mr. W. B. Tegetmeier, London; Mr. T. J. Charlton, Bradford; and Mr. W. Harvey, Sheffield.

THE RABBITS AT THE HANLEY SHOW.

ALLOW me to make a few remarks as to the regulations of the classes for Rabbits. There were three classes, one for the heaviest weight, another for the longest ears, and a third for "any other variety, irrespective of length of ears or heaviest weight." In all these classes Lop-eared Rabbits took all the prizes. Of course they have a right to do so in their own class; and at present I believe they are the heaviest kind of Rabbits. They have, consequently, as good as two classes devoted to them, and against which no one can say anything; but I do not, and I think exhibitors will agree with me, think it fair to admit Lop-eared Rabbits into the "any other variety class," for it is well known amongst Rabbit-breeders that any variety of Rabbit has little, or no chance against the beautiful Lop-eared Rabbit. I therefore hope that the Committee of the Hanley Poultry Show will make some alteration in their schedule as to the classes for Rabbits before another Show.—BUNNY.

PIGEONS.

MATING WITH MEALY—ROUP.

MR. HUIE's article on "Pigeons," in last week's Journal, contains some valuable information, and I think the thanks of fanciers are due to him for it. I believe, however, that he is mistaken in some of his statements, especially where, speaking of matching Yellow Pied Pouters with Mealies, he says, "the produce would be mostly Mealy Yellows, with strongly defined bars." Now, I think this requires qualifying a little, for it surely must greatly depend on how the Yellows are bred. Last spring I matched a Mealy cock with red bars to a Yellow hen bred from a Red, and the produce were three Red cocks, with scarcely any sign of a bar, and a good colour. Besides, are there not such birds as Mealies without any bars at all? If not, I shall be glad to learn what is their proper name.

I can confirm what Mr. Huie says with regard to matching Blues and Whites. It strengthens the constitution of the latter, and the produce will frequently be Whites with blue-splashed tails, which birds, matched to pure Whites, will throw more pure Whites than splashes. I think this is what Mr. Tegetmeier wished to illustrate when he spoke of "the slavish fear of breeding away from some one particular colour." I should not fear, either, to match a White with a Pale Red; of course some splashes would be among the progeny, but they

would be capital birds to match to Whites again. In my opinion this intermixture of colour is the only sure way of getting strength and vigour in one's birds; but I would never cross a Red with a Blue. I should think it the worst cross of any. The produce are smutty Reds, with the edge of each red feather tipped with a bluish grey, which gives the birds a sort of pencilled appearance on the wings. Then the produce of such birds are worse still, even when matched to Reds—Mealies, smutty Blues, Chequers, and Reds, with the traces of the Blue strain still left.

I find roup in Pigeons easily cured by administering a pill every night, about the size of a bean, made of equal parts of gentian, ginger, Epsom salts, and flowers of sulphur, mixed together with treacle to make it bind. This will also cure it in poultry, unless a very bad case. I found the recipe in the "Diary for the Dairy, Piggery, Poultry Yard, and Apiary," by an Essex amateur, which used to be published annually.

I hope Mr. Huie will be induced to give us more of his experience in Pigeon-breeding.—ALFRED HEATH, *Culce*.

THE CANARY CLUB PROJECT.

THE very excellent remarks of your correspondent, Mr. Bedwell, upon this head must, I feel assured, meet with the hearty concurrence of the large body of Canary exhibitors who contribute these beautiful specimens so extensively at the principal shows in the kingdom, foremost amongst which are the Crystal Palace, the Southampton (Hampshire Ornithological Association), the Sunderland (North of England Ornithological Association), and other shows held in the midland counties.

Your correspondent asks some one to assist him in this work, and very handsomely augments his worthy suggestion with the offer of a substantial subscription towards carrying out the object in view. As a secretary of some ten years' experience in the management of these annual displays, I am induced to offer one or two suggestions, which I hope will not be lost sight of should the subject contemplated be carried into effect.

In the first place, a club established on a good, sound, and popular basis would naturally assist local exhibitions in many ways, such as issuing a code of rules for general management of shows, and the adoption of a "Standard of Excellence," whereby exhibitors may be made fully acquainted with the important points of excellence necessary to success. This course, once adopted, will undoubtedly bring under the notice of those interested in the management of shows of this character gentlemen competent to adjudge the Canary prizes, at present unknown to many. I make these remarks without the slightest reflection upon those gentlemen upon whom this difficult and oftentimes unthankful office falls, but in the hope that we shall obtain an infusion of new blood in the list of Canary judges, which, I believe, is acknowledged by men of no small experience in these matters to be a subject quite necessary to the progress of this branch of ornithological study.

Your correspondent refers to one of the most important features of a Canary club—that of holding exhibitions in one of the principal towns every year. Now, to make the holding of these shows a matter of sure success, they should not be held too close together. For instance, they should be held in various parts of the kingdom, adopting some towns where local committees of known experience can be formed to carry out the necessary work.

Another suggestion is that the club be made as self-supporting as possible. One source of its income could be derived from sums being contributed by the innumerable committees of local shows, who, in return, should be allowed the privilege of electing members from their respective committees to co-operate with the principal managers of the club. And further, each subscribing committee should be furnished with copies of the "Standard of Excellence," and be granted such privileges in accordance with the contributions, which should, in my opinion, be on a sliding scale, commencing, say, at 10s., and for each additional 10s. subscribed the greater benefits should be given.

One office I certainly should like to see the club should be called upon to perform,—that in case of any extraordinary dispute arising between a committee and exhibitor, which could not be settled by the local committee to the satisfaction of both parties, that the matter in dispute be referred to the stewards of the club, whose decision should be final. These and innumerable other matters of more or less import could

be introduced into the management, and, I believe, would conduce to the success not only of the club itself, but of the societies who would be in union with it. I therefore venture to hope that the large body of Canary exhibitors throughout the country will avail themselves of this opportunity, and assist Mr. Bedwell to carry into effect his excellent suggestion.

—PHILIP WARREN, Southampton (Hon. Sec. Hampshire Ornithological Association).

SILKWORM-REARING IN ENGLAND.—No. 5.

The most essential requirement in silkworm-rearing is a suitable place to contain the worms. Such a structure in Italy is called *Il castello*, or the castle, and may be manufactured after various designs. One of the most simple and useful is formed by means of four upright posts, which support any given number of stages or shelves, on which the worms are kept. Such a structure must be adapted in size not only to the room in which it is placed, but also to the number of worms to be reared. It is customary to have one for every half-ounce of eggs to be hatched, and most writers allow to the same, in a general way, from five to six stages.

I shall describe one of six stages of full size, allowing somewhat more space than usual; for I am fully convinced that silkworms require more room than they ordinarily obtain. Persons who rear worms from many ounces of eggs should have a castle or two to spare.

My castle has six stages, 12 feet long and 4 feet wide. Each shelf thus contains 48 feet of space, and the whole six 288. Half a dozen such castles could stand end to end, thus making one, if required, or in any other way suited to the room.

The easiest and best way of putting together the tables or stages is to take two splines, 1 inch by 1½, to form the sides. These are placed parallel to each other at 4 feet apart, and are to be connected by nine cross half-inch splines, let into the sides at the bottom, nailing them securely with 1½-inch wrought nails, so as not to split the wood. Thus the stage will be formed into eight compartments, each 18 inches wide, the distance at which each cross piece will be from the other. This frame thus finished should be strong and firm, with its inch edgings upwards, which will serve to prevent the silkworms falling off.

The next proceeding is to cover the inside with some material, which, though tolerably close, will yet admit the air. For this purpose bamboo canes, split up, are much used on the Continent. Some people only put on thinnish wire, forming meshes about 3 inches square, and then cover with rather stiff paper. This kind of netting is very suitable, but I do not like the paper covering, for it will not last much more than one season. I substitute canvas, or some cheap grey calico, which can be tacked on. This, when dirty, can be removed to be washed. The next article I shall more particularly name for covering these tables, instead of the wire, &c., would be reeds, which can be bedded over the cross pieces and secured down by

twine or thin laths nailed to the splines. The table thus covered will present one even surface for the worms, and the cross pieces below will be out of sight, but will be useful, not only to hold the frame together, but as supports over which to place the materials when the worms spin. If desired, the ends of these tables could have cross pieces like the side rails; thus there would be a protection against the worms falling from thence, and equality all the way round. Where, however, these castles are erected to stand end to end, this precaution is not required.

It now remains to prepare four square or round posts, very strong and straight, about 3 inches in diameter and the height of the room, which for this castle should be at least 10½ feet. These posts are each to have six holes, 1 inch in diameter, drilled through them, all in a perpendicular line up their sides, to receive 6-inch pegs—viz., 3 inches will be inserted in the posts and 3 inches will project from them. These pegs are to be about 18 inches apart, 18 inches from the floor of the room, and rather more from the ceiling. These prepared posts are then placed upright between the floor and ceiling, and made quite secure by wedges if necessary, or if they could be let into the ceiling, and fastened to the beams there, all the better; at any rate they must be secured firmly.

The posts are placed upright in pairs, with the pegs facing, at 4 feet apart, or the width of the stages they have to support, and which rest on the pegs, one above the other, at 18 inches apart. The ends of the stages may project beyond the poles nearly a yard, and be secured to the pegs to avoid the danger of shifting. Some persons instead of pegs put pieces of wood or rails entirely through from post to post, forming a kind of ladder, on the staves of which the stages are laid, but either mode will answer the purpose well if stability be insured.

The above description of a silkworm house will answer for all systems generally adopted, whether on a large or small scale. Some are erected to swing by ropes from balks in the ceiling, without touching the floor; some are suspended from the walls, and others have the posts provided with feet, which are very necessary when the castle is small, and does not extend up to the ceiling. Such a structure of half the size I have described could be made for even parlour use, with any polish and embellishment desired. I have studied economy and use, and leave all decorations to the will of my readers.

In case of erecting stages round the walls of a room, to which there is no objection provided the ventilation is not impeded and the walls are dry, they must not be above 2 feet in width; for, unlike the castle I have described, no person can go round them to perform the necessary work in attending the worms. Two feet is a sufficient distance for a moderate-sized person to reach without incommoding the insects.

There is a custom among many silkworm-rearers to make use of boards for these stages, but they are not so suitable. Expert rearers condemn them. The air cannot penetrate to dry the worm's excrements, &c., which, collecting, soon putrefy, producing an unhealthy fermentation beneath the worms, giving off carbonic acid gas, which is very injurious, laying the foundation of all the direful diseases which attack silkworms. I must, therefore, impress fully on my readers the necessity of using stages, of whatever material constructed, through which the air can pass.—EDWARD HARMAN, JUN.

UTILISING AND UNTING CONDEMNED BEES.

ONE of the most interesting, and certainly not the least profitable modes of turning a moderate amount of practical apiarian knowledge to account, is, during the autumn, to sally forth and collect all the condemned bees from farmers and cottage bee-keepers within a radius of from four to five miles, and having expelled them from their habitations by driving, convey them to one's own apiary, there to be applied either to the strengthening of such of our own colonies as may happen to stand in need of a reinforcement, or to be established as new stocks, and by a liberal supply of simple syrup fed up to a sufficient weight to stand the winter. It is, of course, to be hoped that in process of time there will remain but few bee-keepers who have not attained such a very moderate amount of practical bee knowledge as may enable them to drive and unite bees for themselves; but pending the arrival of that golden age, whose advent I am always ready to assist in bringing about, but which still appears to remain so very far distant, the more advanced bee-keeper may find both pleasure and profit in devoting some of the glorious afternoons with which we are

favoured during the autumn to bee-driving expeditions—a pleasure which must be increased by the reflection that he is thereby rescuing countless thousands of industrious little labourers from a violent and untimely death, and by profits, the value of which can scarcely fail to be enhanced by similar humane considerations.

When about to start upon one of these expeditions, I secure beforehand the services of a small boy, who propels before him a nondescript kind of trap, composed of the wheels, lower frame, and springs of a child's perambulator, from which the seat has been removed and replaced by a horizontal platform, formed by a light wooden frame nearly 4 feet long by 15 inches wide. Upon this are ranged four common straw hives, tied up in as many bee cloths, and a small leather travelling bag, the whole being well secured by a piece of stout patent sash-line, passing from front to rear, and strung through a loop in the top of each hive and through the handles of the bag. This latter contains the following articles: A piece of coarse towelling 1½ yards long by 8 inches wide, rolled up, with the end secured by a stout pin, and 6 yards of small cord wound round it, a fumigating tube charged with cellar fungus, a box of matches, a short iron skewer, a small packing needle, threaded with a yard or so of stout twine, two or three little boxes made of perforated zinc, and fitted with sliding covers, a set of three honey knives, a couple of sheets of newspaper, a piece of half-inch wood, 18 inches long by 8 inches wide, one or two strong quill feathers, half-a-dozen pieces of small cord or stout twine, each from 1½ to 2 yards in length, and a veil for shielding the face in case of necessity, which latter is, however, but seldom used.

Arrived at the scene of action, I first ascertain what stocks are to be operated on, mark every one distinctly, either by at once removing the straw hackle or in some other equally unmistakable manner, and obtain the loan of an empty bucket, with a couple of kitchen chairs, all of which are forthwith conveyed to the apiary.

And here, whilst repeating the confession which I made in page 188, that I know of no mode of uniting adult bees, which is free from the chance of an occasional failure, I may be permitted to acknowledge my belief that we are indebted to the Rev. P. V. M. Fillenul for the first discovery of a fact upon which are based all my more recent modes of uniting bees, and by which it seems to me that the risk of failure is reduced to a minimum. It is, I believe, some eighteen years since that accomplished apiarian, writing under the *nom de plume* of "A COUNTRY CURATE," informed the readers of THE COTTAGE GARDENER that he had found that if the inhabitants of two or more stocks of bees were driven in succession into the same empty hive, a peaceful union would be the result. A very considerable amount of experience having satisfied me of the general truth of this axiom, it will be found that the manipulations which I am about to describe are substantially based upon it.—A DEVONSHIRE BEE-KEEPER.

(To be continued.)

OUR LETTER BOX.

LICE ON FOWLS (D. H.).—Complaints of lice always come after a wet time. When all the land is saturated, birds cannot find their dust bath, and that is the only remedy or preventive for this affliction. Every poultry run should be provided with some sheltered place, and this should be supplied with fine dust, road-grit, and bricklayers' rubbish in heaps. To these, or to either of the first, should be added some black brimstone, of the commonest sort, in the proportion of a pound to a bushel of sand. The birds will show their need of it by running to it, as a thirsty man does to water. There are other parasites besides lice, and some of them are visible only through microscopic agency. By that help they may be seen clustering round the poll of a chicken in heaps, or suspending themselves in bunches. The immediate cure for that is to rub oil on the poll, along the backbone, and under the wings. They are the parts specially chosen by these pests. We believe this will cure yours. We have treated your question generally, because we think that by making proper dust baths you should have no such plague among adult fowls. Chickens when out of health will be subject to them. We do not think cinders or ashes, except wood ashes, make good dust baths. Cinders are worse than nothing, as they stick in the feathers and torment the birds. If you have given such they may partly cause the discomfort manifested by the birds. Partridges will teach you a lesson on dust baths. When we have had long wet weather you will find in every light-soiled beetling bank under the naked roots of trees, regular recesses formed by the birds using it for their baths, and the traces left of its constant use.

PLUMAGE OF DARK BRAHMA POOTRA COCKEREL (John Milton).—Black feathers tipped with white are not objectionable on the thighs of a Brahma cock.

POULTRY VARIETIES IN ONE RUN (J. H.).—The effects of promiscuous intercourse we believe not to cease until a hen has laid her whole season's eggs and become broody. Some poultry-keepers, however, think that after three weeks the effects have passed away.

BRAHMA POOTRAS (E. H. W.).—There are no such birds as "White" Brahmas. They are called "Light;" the body is white, but the backle, tail, and flights are black. Coloured Brahmas will do very well in confinement, quite as well as or better than Cochins. Dorkings will not do in confinement. We always shudder when we hear of fowls in a yard. We picture to ourselves one paved with flagstones. Some years since we were staying in St. Leonard's, in Eversfield Place, and looking out of the back window could see half a dozen melancholy birds standing about on one foot on large flagstones that were carefully washed every morning—flat-footed birds that had lost the habit of scratching, that only saw the sun for half an hour in the twenty-four, that turned with loathing from the "tousjours perdrix" of the clean barley lying on the stones to the variety of the dust heap. Fowls will do us anything but flagstones, bricks, or boards.

EARLOBES OF BLACK BANTAMS (B. H. M.).—Black Bantams must have white deaf-ears. They are by no means necessary for White or other colours.

CROOKED BREAST (R. H. I.).—This deformity in fowls usually arises from constitutional weakness—like the rickets in children. The chickens are stimulated into rapid growth, so that their amount of muscle is far out of proportion to the growth of the bones. These being in a gristly state, and the muscles on one side being more developed than on the other side, the breastbone is soon pulled into a crooked form. Nourishing but not stimulating food, rusty iron in the water trough, plenty of green food, and a good run, are the best preventives. Never breed from a crooked-breasted fowl—"like begets like."

MALT DUST (A Constant Reader).—You may generally obtain malt dust at any corn-dealer's in the country. It may be given as a stimulant mixed with barley meal.

DUCKS (J. T.).—You can keep Ducks in any place, where you can give them an outlet either into a yard, or to grass or garden land. They require but little water, and are by no means dainty. It is not necessary to keep a drake, unless you intend to set the eggs. If you send to our office seven postage stamps with your address, and order "Poultry Book for the Many," you will have it sent free by post. It contains directions for keeping Ducks.

INCUBATOR (A Subscriber).—There are several makers of them, and we cannot venture to recommend one more than the others. You will see the advertisements in some of our back numbers. Write to the makers for information and select for yourself.

ISLE OF PENC.—"T. C. H." will be much obliged by "W. H. K." stating in what atlas or work this island is mentioned.

CANARY SEED (Hercford).—Retailers must have a large profit, or it would not be worth their attention. The portraits you refer to never appeared before in our columns.

CANARIES (Lucien).—If you send twenty postage stamps with your address, and order "The Canary," the book will be sent to you free by post. It contains full directions for their management.

RED LICE IN CANARY CAGE (Burnley).—Lime will not destroy them, but flowers of sulphur rubbed into all the openings, and a little mixed with the sand on the cage floor, will exterminate them.

HEX HOUSE FLEAS (A. D. E.).—Several of the feverfews, especially *Pyrethrum roseum* and *carnium*, if dried and powdered, and sprinkled about the house, are said to drive away fleas.

PIGEONS HAVING INCASED FEATHERS (H. W.).—Your Pigeons have not moulted freely, a general complaint this season, caused by the protracted damp and cold weather after harvest. It is well the feather has fallen out, and if the bird lives it will be replaced by a new one during spring. Indian corn is good feeding; add, if possible, a few small tick beans and vetches, but spare your wheat till the breeding season; the harder the food the better during winter. The short breathing proceeds from weakness, and often appears in Pigeons that have not moulted freely. Keep your birds warm and dry at night, this is of great consequence. Give them plenty of clean water to wash in, daily if possible. Use a large vessel about 3½ inches deep. Washing is life to all birds that do wash. Fill an 8-inch flower-pot saucer with fresh garden or field earth, free from manure or chemicals, and mix well through it half a tea-cupful of salt; all your birds may peck freely at this mixture, of which they are very fond, you will find this improve them quickly both in health and plumage. Should the salt appear to purge (as it may do at first) remove it for a few days. Give plenty of old bruised mortar, and let your birds fly if convenient in dry weather. Your sick birds may have a handful of hempseed once or twice a week, but if the seed is not digested by morning give no more of it.

BARNS FOR SUPERS (C. A. J.).—We use the same bars in supers as in stock hives, but place them a little wider apart, using only eight instead of nine bars in a 13-inch box.

GRATINGS TO EXCLUDE DRONES (Idem).—Gratings with apertures three-sixteenths of an inch wide are used to exclude the queen and drones from supers.

REVOLVING FRAMES (Idem).—We believe that the German centrifugal machine extracts all the honey from combs without injuring them in any way.

SIZE OF NUCLEUS BOXES (Idem).—Our nucleus boxes are 6½ inches wide inside, and accommodate four combs in each at equal distances apart.

COMBS BEYOND THE BARS (Idem).—When there is an overflowing honey harvest bees will crowd every available cranny in their hives with combs, even the space which is left between the ends of the frames and the sides of a Woodbury hive. The occasional slight obstructions thus caused to the removal of the combs can readily be cleared away, and are a much more trivial inconvenience than would be experienced in manipulating frames in an unduly contracted hive.

POULTRY MARKET.—JANUARY 22.

The supply of the market is small, but small as it is, there is scarcely trade enough to consume it. There is great depression in every branch.

From observations taken near London during the last forty-one years, the average day temperature of the week is 45.1°; and its night temperature 31.3°. The greatest heat was 57°, on the 1st, 1852; and 3rd, 1859; and the lowest cold 8°, on the 31st, 1857. The greatest fall of rain was 0.75 inch.

BRUSSELS SPROUTS.

TO grow this useful winter vegetable successfully the seed should be sown in the first or second week in January in pans or boxes, and placed in a cold pit, late Peach house, vinery, or any place where there is sufficient warmth to cause the seeds to vegetate, and where the young plants may have abundance of air at all times without being injured by frost. The seeds should be scattered thinly over the surface of the soil in the pans or boxes, and just covered with any light soil. If the seed is sown too thickly, and the pans should have too much water at any time during the dull and sunless weather generally prevailing at this season, there is danger of the seedlings damping-off. The pans should have only just sufficient water to keep the young seedling plants from flagging; if the soil is tolerably moist when the seed is sown no water will be required before the end of January or the second week in February.

About the end of February the young plants should be pricked-out, about 3 inches apart, into other boxes or pans, and placed in a position where they will have the benefit of a little more warmth till the end of March. During this time they should be kept rather dry, giving them water only when they show signs of flagging. The soil into which they are pricked-out should not be pressed too firmly into the pans or boxes, and should be composed of two-thirds leaf soil and one-third loam. In this the young plants will root very freely without making very much growth; the scanty supply of water will also prevent their growing very rapidly. During this time they will be gaining strength and maturity, and will show the benefit they have derived from their early treatment.

On planting-out in the open ground, about the second week in April, the young plants should be carefully shaken out of the soil they have been growing in, when it will be found that each plant has a fine mass of roots attached to it. Having selected as many plants as will be considered necessary for the purposes of the family, they should be carefully planted-out in an old pit or frame, about 6 inches apart, in good soil. Here they should have all the air that can possibly be given them. After they have been planted a week or ten days, about the first week in May the point of each plant should be pinched-out, and as soon as the plant begins to push-out side shoots, three or four of the most prominent should be selected to form the future stems, and all the others should be removed. This is the most important point to which I wish to direct attention, for the adoption of the practice will enable one to grow four times the quantity of sprouts of first-rate quality on one plant that could be obtained in the ordinary way of cultivating Brussels Sprouts. The plants may remain in this position till the first week in May, when they may be removed to the open ground, and be permanently planted.

Having described the early spring treatment from the sowing of the seed to the period for planting-out in the permanent beds, I will proceed with the after-treatment. It is necessary that the soil should be good and

deep. Having selected the piece of land in which the plants are to be grown, place regularly over it a good layer of manure about 2 inches thick. This should be worked into the bottom of each trench as the ground is trenched or dug. The ground may be thrown up in little ridges or left in rough spits, but it is important that it should be prepared in this way for the crop as early in the autumn or winter as may be convenient. In the first week in May, when the plants are ready for planting-out, the ground may be slightly dug over for the purpose of levelling it; drills should then be drawn at 4 feet apart, in which the plants may be planted after taking them from their spring quarters with good balls. They should be carefully planted with a trowel, not with a dibber, 3 feet apart. The soil must be pressed firmly about the roots, and the operation of planting should be finished by giving them a good watering, and placing a stick to each plant.

The stick should be pushed into the ground to a proper depth to enable it to support the four stems when sufficiently advanced. It should be about 4 feet long; this will admit of a length of 1 foot being pushed into the ground, leaving 3 feet of it above the surface, to which part the four stems may be made secure. Each shoot should be tied to the stick as soon as it has grown 4 or 5 inches long; this will cause the shoots to grow perfectly straight, and prevent their being split off from the parent stem by high winds; and as the shoots mature their growth, they should be gone over occasionally, and fresh ties added to keep them in their places.

During the summer months the plants should be copiously supplied with manure in a liquid state; the decaying leaves should also be removed. This will allow the small sprouts to develop, and will also permit the air to circulate freely amongst them, causing them to assume that dark green colour which adds so much to their appearance and flavour. If Brussels Sprouts are wanted early in the autumn, the tops should be broken out of a score or two of the plants, this will cause them to mature their side sprouts much earlier than they would otherwise do.

To have a regular succession of Brussels Sprouts from August to April it will be necessary to make three sowings—namely, the first in the first or second week in January; the second in the first week in February; and the third in the first week in March. The first two sowings should be treated as previously recommended, but the third may be made in the open ground. The plants from this sowing should not be stopped, as there will not be time for them to mature their new stems and to clothe them with young buds before the winter sets in, except in very warm localities.

Many advantages will be gained by cultivating Brussels Sprouts in the way I have described, and the trouble is not so great as at first it may appear. I feel confident that even market growers would find it would pay them to cultivate their Brussels Sprouts in this way, for each plant may be made to produce four times the number of sprouts, and these of a much superior quality to what we commonly see. Generally a large number of the plants in every piece of Brussels Sprouts will be found either blown over

by the wind or borne to the ground by their own weight; the consequence is that one-third of the sprouts is rendered useless and unfit for sale, whereas if grown in the way I recommend not a sprout need be spoiled, and all are rendered saleable. Besides, for a gentleman's garden, when we take into consideration the neat appearance of a plantation of Brussels Sprouts grown as described above, I think I may safely call the attention of cultivators of this useful vegetable to the system of culture I have described, well knowing that the result to be gained will more than repay them for the additional trouble they may be put to.—J. WILLS.

CULTURE OF LAPAGERIA ROSEA.

LAPAGERIA ROSEA is one of the finest greenhouse climbers in cultivation, and, what adds to its value, it flowers during the winter months, when almost any flower is welcome. It is, however, not so universally grown as it deserves to be, and when it is to be found in collections of plants it is not always in such good health as desirable. A few years ago plants of it were expensive, it being generally propagated by layering; but now seeds are ripened in the London nurseries, and hundreds of seedlings are raised. This is a much preferable way of propagation. Plants can now be purchased at half a crown each—a price which places it within the reach of the most humble cultivator of greenhouse plants.

I shall suppose that a small plant has been obtained, and that it is growing in a 60-sized pot. It ought to be placed at once in the warmest part of the greenhouse, for although it is a greenhouse plant, it will do with more heat and less air than most. I have cultivated Lapagerias in the plant stove, but I do not recommend stove culture for them, as the plant is more liable to be attacked by parasites. That most difficult to dislodge after it has gained any degree of ascendancy is the mealy bug, of which the strips of matting that the shoots have been tied-in with are favourite hiding places, and the ties must all be undone that the plant may be washed, much damage resulting to the plant during the operation. In the stove it is also liable to the attacks of thrips, which can easily be destroyed by smoking with tobacco, and the sort I find most effectual is shag, at 2s. 6d. per lb., which is cheaper than most tobacco paper at 1s. 6d. I have also found that in a stove neither the flowers nor leaves exhibit the same bright healthy appearance which they have when the plant is growing in a greenhouse temperature.

When the plants are well established in 60-sized pots they ought to be shifted at once into pots 6 inches in diameter, inside measure, taking care that plenty of drainage is placed carefully in the pot first, and over the drainage a little rough turfy peat, from which the finer particles have been sifted. The materials in which the plants are to be potted ought to be turfy peat torn to pieces instead of being chopped up with a spade, and used without any admixture, except some silver sand if the peat is deficient in sand, which some sorts of peat require, and of which others contain enough naturally. The addition of a little charcoal is also sometimes beneficial.

The Lapageria requires plenty of water during the growing season, but it can be overwatered; and if the material in which it is potted becomes sour, either from careless watering or bad peat, it will soon become unhealthy. There are some sorts of peat which retain the water until they are converted into a soapy mass, from which every particle of fibre will have disappeared; and if a handful is taken up and squeezed, the inky water will ooze out between the fingers. In peat of this sort no plant will thrive, hence the importance of selecting good peat; if on squeezing it in the hand it leaves a stain it may be safely rejected as unsuitable for any gardening purpose.

The Lapageria is a slow-growing plant, and will not make much progress the first year; but in twelve months, if the pot is full of roots, it may be shifted into a 9 or 10-inch pot, and when it has filled that size with roots, which may be in twelve months more, it may be shifted into any size ranging from 12 to 18 inches, and a trellis must be provided for it. That which I admire the most is one I have seen in use for the purpose at Messrs. Veitch's, of Chelsea, and which is somewhat umbrella-shaped. The shoots are trained up what may be called the handle of the umbrella, and under and around the framework. They ought to be trained so that the greater part of the flowers may hang from the outer circle, and in this way the plant has a most charming effect.

I have proved from experience that the Lapageria succeeds well when cultivated in pots, but it does equally well, if a suitable position can be obtained for it, when planted out in the greenhouse or conservatory. A border ought to be prepared for it by excavating the soil to the depth of 3 feet, placing at the bottom of the border 1 foot of broken bricks, and over these a layer of turfy peat with the grass side downwards, filling up with the same material as previously recommended for pot culture, only using it rougher. The lumps of charcoal should be from the size of a pigeon's egg to that of a man's clenched fist. Treated in this way it will grow freely, and will require little attention, except training the shoots, not allowing them to twist round wires. It is also much benefited by being occasionally syringed during the summer months.—J. DOUGLAS.

HEATING BY STOVES.

I, as well as other readers, feel indebted to "J. W." for his interesting article on stoves for small greenhouses, vineries, and other structures, more especially as many who have small houses are deterred from using them, by many reported failures of those who have tried them, and given them up because they found the simple management too troublesome. I have frequently stated that for small or even moderate-sized single houses there is no mode of heating that will compare with the stove, as respects economy of fuel. I do not even object to an iron stove, but I would like these two conditions to be fulfilled: First, the stove should be so large as to have the firebox lined with firebrick, and an open space for fire of 8 or more inches square; this box to stand an inch or two free of the sides of the stove. Secondly, the top should be flat, or level, so as to receive a vessel of water.

"J. W.'s" plan seems to combine most of the good points of the iron stove and the brick stove. There is just one point on which I should like to have a little more information, and that is the length of time the arch of sheet iron (*d.* in the section), may be supposed to last. I am sure that "J. W." will give his assistance here, especially when I assure him that even from my own correspondence such a mode of heating small places is very much considered by those who are able to afford no other mode of heating. From my own experience all plate iron exposed directly to the fire very soon burns out. When iron stoves are used in churches and chapels, and sheet-iron pipes are used to carry off the products of combustion, two or three new pieces are generally required every winter. In this case the smoke and soot as well as the fire eat into the metal, and there would be little or no soot on the arched plate in the section on page 28. True, the plate could be easily replaced, but it would be as well to have an idea of its probable duration.

I have not a doubt but that the plan answers admirably; and it will save the smoke pipe being seen when it can be taken into a back wall, but I do not think the heat will be so equally diffused as when the stove is near the front, or the middle, instead of the back of the house. Other circumstances, however, being favourable, I would prefer even a little larger stove against the back wall of the house, as it interferes less with the internal arrangements.

In the desire for simplicity, the iron casing may even be too complex for some who would like a mellow heat than can be obtained from an iron stove, without extra care and trouble, unless the firebox is free of the sides of the stove. For their sakes, without in the least depreciating the plan of "J. W.,"—quite the reverse—I would say, that they will succeed by following his plan of a firebrick firebox, &c., substituting brick for the sand and iron, carrying the walls up square, and having a plate of iron one-half to three-quarters of an inch thick over the top. This may be let into the bricks with a sand joint all round. If I wished to be particular I would here borrow from "J. W.," and do just what we do with an old iron stove—have a piece of sheet iron over the top, resting at least on 2 or 3 inches of the brickwork, and therefore all that larger than the opening above the fireplace, on this place from 1 to 2 inches of sand, and the heavier plate—say, from a quarter to half an inch thick, above that. In this way, merely by moving the upper loose plate, and taking off the sand, the interior of the stove could be examined at any time.

By such a simple mode, and that also so well followed out by "J. W.," the principle of the Arnott's stove, whether of iron or formed of brick, is so far departed from that after the heat from the fire has come in contact with the top of the stove, there is

no mode resorted to for preventing that heat finding its way to the smoke vent. This could be easily done by fixing a fire-brick or lump in front of that opening, but from 1½ to 2 inches from it, which would cause the heat to beat more against the sides of the stove before escaping by the chimney. So far the theory is right and feasible enough; but in practice, if the smoke pipe goes out at the side of the stove, and if that opening is 6 or more inches from the inside top of the stove, and if the ashpit door is close, from whence the air for combustion almost alone must come, then such partial blocking-up of the outlet is of little or no consequence. Anything of the character of a damper in the smoke chimney would also prove an annoyance.

Some time ago I wrote on the importance of such matters as those above referred to, and without experience I would not have credited that heat could be so regulated and economised—that is, kept in the stove, merely by regulating the air admitted at the ashpit opening. On lighting an old iron stove here, the ashpit drawer is generally pulled out. As the fire burns it is put partly in, and when the fire has fully taken hold the drawer is put in altogether, and three small slits one-eighth of an inch wide and an inch long are left open until the stove and the 3-inch metal pipe through the roof become tolerably warm. A length of about 7 feet of that 9-foot pipe is upright in the house. With air on at the ashpit door, even with these three slits open, the pipe close to the roof will be almost as warm as the stove, showing clearly that then a good portion of the heat from the fuel is escaping into the open air; but when we close two of these air-slits, it is a long time before the heat is at all diminished in the stove, but the upper part of the pipe soon becomes cool, showing that but little heat is escaping into the open air. The regulation of air by the ashpit door has, therefore, a great effect in economising heat, and does, in fact, what otherwise might be effected by blocks and dampers. Every ashpit door left open when the fire is established, proves incontestably, whether connected with a stove, furnace, or boiler, that the fireman is either ignorant or too careless to practise what he knows. Such a simple matter as leaving ashpit doors open in the case of common furnaces is only of little importance where fuel is of little value. I hope that all who have commenced, or intend commencing with these stoves in their small houses, will carefully note the statements as to successful management in "J. W.'s" excellent article.—R. P.

ARAUCARIA CUNNINGHAMII SINENSIS.

We have here three plants of this very ornamental variety, which Mr. Smythe informs me have been planted out on the lawn, and withstood the severity of our winters uninjured for eleven years. It is of a very graceful habit, and a much faster grower here than *Araucaria imbricata*. The tallest is now 6 feet high, 6 feet 6 inches in diameter of branches, and during the last two seasons the leader has made a growth of 18 inches each season.

As this *Araucaria* is said by some to be tender, I should like to hear the experience of any of your correspondents who may have tried it.—Thomas Winkworth, *Elmhurst Gardens, Thetford, Norfolk*.

GALVANISED WIRE FRUIT TRELLIS.

In the *Journal* of January 16th Mr. Radcliffe recommends a galvanised wire trellis for Peach and Nectarine trees; and in the same number Mr. Abbey also recommends galvanised-iron wire for garden walls. On the contrary, I had arrived at the conclusion that galvanised-iron wire is injurious to Peach and Nectarine trees, causing canker in them.

I first saw galvanised wire used some six years ago. It was stretched horizontally in front of the wall at the distance of about 2 inches from it, and had a very neat appearance. I had the management of the trees, and I found wherever any of the shoots were tied too tightly, so that the shoot was pressed against the wire, it would most likely be cankered; and I was confirmed in this on reading an answer to a correspondent in another periodical, wherein it was stated that galvanised wire is injurious to Peach and Nectarine trees. Painting the wires was recommended; but if wires are intended to be painted they ought not to be galvanised first, as wire is made exceedingly brittle in the process.

Further, being on a visit to my friend, Mr. Wilkie, gardener at Oak Lodge, Kensington, only a few months ago, I saw

canker on some of the shoots in the Peach house, and I remarked to Mr. Wilkie that I thought it was owing to galvanised wire being used, which, although it had been painted, was worn in places.

I should like to know if I am wrong in my impression, as I have never since used galvanised-iron wire as a trellis.—J. DOUGLAS.

THE MISTLETOE IN FRANCE, TURKEY, AND AMERICA.

ALLOW me to add a few particulars to those given by your correspondents respecting the growth of the Mistletoe in France. I can speak from experience, for I have travelled through the country in almost every direction where there is anything of interest.

The Mistletoe is abundant throughout the east, west, north, and centre of France, and more especially so in the districts where fruit trees are grown (chiefly Apple and Pear trees), and in the valleys of rivers. Nowhere is it so plentiful as in the valley of the Loire and those of its tributaries. At Indre, Nièvre, Sarthe, Loiret, and some other parts, it occurs almost exclusively on Poplars in moist places; and the Black Italian Poplar (*Populus virginiana*), and the Carolina Poplar (*P. angulata*), are more favourable than any other to its growth. This circumstance is easily explained. The seeds of the Mistletoe are contained in a white berry, of which the viscous matter adheres to them even after having been digested by the thrushes, which are very fond of the berries. The birds in winter often leave the woods for the borders of the rivers and streams, to seek for insects, which are more numerous in the sheltered valleys than in the open fields and the woods. At nightfall the birds perch on the tops of the tallest trees (Poplars), and the droppings which fall on the branches frequently contain Mistletoe seeds, which stick to the bark. In the following spring the parasite germinates, and grows rapidly at the expense of the abundant sap of the Poplar. In orchards it is likewise the thrushes that deposit the largest number of Mistletoe seeds on the Apple and other fruit trees; but this is chiefly done when the fruit is ripening, that being the time when the birds take up their quarters in such places. Other birds assist the thrush in disseminating the seeds, but thrushes are the principal agents.

I may add that everywhere in France this parasite is sought for and destroyed, as it is very injurious to the trees on which it grows, by feeding on the sap.

It has been observed that the Mistletoe is much more abundant on trees with spreading branches than on those of fastigate or pyramidal habit, such as the Lombardy Poplar. It is also found on Lime trees, the Ash, Willows, and softwooded trees, but very seldom on hardwooded trees, such as Elms, Beeches, and Hornbeams; and still more rarely on leguminous trees, such as *Cytisus*, *Robinia*, and *Sophora*.

Botanically the Mistletoe is not affected by the different trees on which it grows; that question has long since been studied. That the Mistletoe does grow on the Oak cannot be disputed; but its existence on that tree is exceedingly rare, not more than two or three instances being known in France.

The *Salvia* of which the name was lately asked is *Salvia horminum*, which is common on the Pic du Midi and Col de Tende.—EDOUARD ANDLÉ, *Puyg*.

ONE inquiry I would like to make of your St. Malo correspondent, and that is, Is the Mistletoe found on the Oak in any quantity in the part of France she writes from? In England, as mentioned in my former note, it is very seldom found on that tree, although at an earlier period of our history it may have been more plentiful. It would be interesting to know if it exists in western France on the Oak in any quantity, and if so, possibly cultivation may have had some part in driving it away.

Your correspondent's picture of its abundance in Brittany is at variance with the idea of good fruit being plentifully produced there, as the healthiest and most vigorous trees are not likely to support this parasite; at least, it is not so in England, where the best cultivated districts produce least Mistletoe—in fact, I may say that it is but rarely met with on Apple trees under twenty years old, and many healthy trees of double that age are free from it. It has, however, its favourite localities, and in such places attacks trees of a younger growth than it does elsewhere. The question would naturally arise,

Does the lack of vigour in the stock, as we may properly call the Apple, favour the growth of this singular production, or is it due to some climatic influence, as healthy free-growing fruit trees and abundance of Mistletoe are not often met with close together? The scarcity of Mistletoe in some districts is also due, in some measure, to the care taken to remove it, as many fruit-growers have it destroyed, as far as possible, in winter; and the purveyors for the London public, by legal or clandestine means, for both are adopted, contribute much to the same result before Christmas. This destruction of Mistletoe, improved cultivation, and other causes, tend to render it less plentiful than it was in the past, and, perhaps, when western France shall be as carefully and industriously cultivated as the home counties in England, the Mistletoe may, like many other things once plentiful, disappear by degrees, especially when the old fruit trees are replaced by young ones, and encouraged by manure and good cultivation to retain their vigour to a later period than their predecessors.—J. ROBSON.

PERMIT me to inform Mr. Robson, through your paper, that the Mistletoe grows most luxuriantly in the orchards round Sautari, many of which are within a mile of the sea. I have seen pieces brought into the hospital there in the winter of 1851, which were as much as two men could carry.—JOHN E. BARNES, *Clare, Suffolk.*

MR. ROBSON states in his letter that he believes that the Mistletoe is more plentiful in England than in any other country. I would most respectfully state that I have found the Mistletoe more abundantly in some parts of America than in any part of England in which I have been, although I have seen it growing very fine in some districts in England, but not equal to what I have found in the States.

In the spring of 1862 I was travelling from St. Louis, Missouri, to Vicksburg, Mississippi, down the Father of Waters, as the Mississippi is called over there; and after leaving St. Louis some distance I noticed what appeared to me to be a continual rockery, but could not see any rocks; so at one of the numerous wood yards where the steamer stopped for fuel I with several others went on shore, and to my surprise and delight I found the supposed rocks' nests were masses of our dear old friend Mistletoe. Many a noble bough was there, which, had it been in merry England, would have been greatly prized, but it is thought little or nothing of by our fast and go-ahead cousins.

I find the Plane tree (*Platanus occidentalis*), its greatest favourite, although it grows abundantly on the Red-flowering Maple (*Acer rubrum*), and *Carya alba*, the Hickory; but I have never found it on the Oak. It is found for several hundred miles down the Mississippi river, and in some parts of Arkansas, on White River, and St. Francis; also near the seacoast in North Carolina, especially near Wilmington on the Cape and North-East rivers, both of which are noted for swamps, and in these the Mistletoe seems to delight.

I am of opinion that the sea breeze and saline atmosphere are not detrimental to the growth of the Mistletoe, as I have seen it growing near the seashore a little above Fort Fisher, N.C., quite as luxuriantly as on the Mississippi, a thousand miles from sea.—ALPHA.

[We think the species thus noticed in America was *Viscum flavescens*, or Yellowish Mistletoe.—EDS.]

TO SET THE MUSCAT OF ALEXANDRIA LIKE THE BLACK HAMBURGH.

KEEP the day temperature at 75° by fire heat, and 85° with sun heat. Keep the night temperature at 70°. Damp the paths at 7.30 A.M. and at 4 P.M. Keep the whole of the atmosphere of the house in perpetual motion, night and day. When the blossoms are fully expanded give each bunch a slight shake once a-day. This is all that is necessary to insure well-formed bunches.—R. BUDD, *Gardens, Cobham Hall.*

PROPAGATING DRACENAS.

I was much pleased with Mr. Newlyn's notice on the genus *Dracena*, but he appears not to be aware with what great facility the genus may be propagated.

Any plant that has become too leggy may be cut down to

the pot, the stem cut into 1 or 2-inch lengths, and planted the same as Vine eyes. If placed in a good bottom heat they will make nice little plants in one season either for the decoration of the stove or flower garden. In the latter situation a few of the species do tolerably well, and are highly ornamental.—W. ROBINS, *Oakley Park, Suffolk.*

REPORT ON THE PRESENT STATE OF HORTICULTURE IN THE ISLAND OF JERSEY.

THE Royal Jersey Agricultural and Horticultural Society appointed a Committee to visit during last August various parts of the island, and to report on the state of its horticulture. That report is now before us, and is highly interesting and satisfactory.

The Committee visited many gardens—Beaulieu, the residence of F. Bertram, Esq.; Clifton House, Misses Ainge's; Government House, Major-General Burke Cuppage's; Spring Grove, Capt. Howell's; The Vineries, J. Pond, Esq.'s, where four tons of Chaumontel Pears were grown last year; Belle Vue, Col. Le Couteur's; Oak Walk, the Rev. P. A. Le Feuvre's; Trinity Manor, C. P. Le Cornu, Esq.'s; Rozel Manor, the Rev. W. Lemprière's, and La Chaire, Mrs. Fothergill's. We cannot spare space for a detailed notice of more than one of these well-cultivated gardens, and it shall be the last named.

"La Chaire, the property of Mrs. Fothergill, formerly belonging to her father, the late Samuel Curtis, Esq., F.L.S., Editor of the "Botanical Magazine," and a well-known botanist and horticulturist, is perhaps the most extraordinary triumph of horticultural skill in the world. Mr. Curtis took pleasure in telling, with a well-remembered smile, the small outlay originally required to purchase this now valuable property, and how his neighbors and friends congratulated him with irony on his acquisition. But the eye of genius saw the capabilities of this apparently useless and barren hillside. This unique garden has been visited by some of the most eminent men of the day, amongst others by the late Sir W. Hooker, Curator of the Royal Kew Gardens, by Mr. Babington, F.L.S.,* and by Mr. Bentley, F.L.S., F.R.H.S., and Professor of botany at King's College, &c., all authors of standard works on botany, and is with unusual liberality always open to visitors, thousands of whom, during the season, avail themselves of Mrs. Fothergill's kindness; and your Committee learn with pleasure that it is very rarely that any damage is done by them.

"The trees and shrubs which now cover the whole surface of this once unpromising spot, are, from their rarity and luxuriance, the admiration of all visitors. Many shrubs, which in England require protection, grow here without it; and are now so large, that it would be impossible to house them. Many of the rarities were sent to Mr. Curtis, by Sir W. Hooker, in exchange for specimens from here. Of *Acacias*, fifteen varieties are grown, some of them large trees, which in early spring are masses of bloom, and perfume the whole air of the valley; of *Magnolias*, four varieties; of *Rhododendrons*, over twenty varieties, including most of the much-prized Himalayan varieties and many hybrids; of *Eucalyptus*, or Australian Gum Tree, four varieties; of *Hydrangea*, four; besides, thirty-six other species of foreign trees and shrubs, prominent among which are the well-known *Wellingtonia gigantea* and the Cedar of Lebanon.

"The gardener, Mr. Beckford, who, single-handed, keeps this romantic spot in perfect order, deserves the highest praise for its cleanliness, and for the vigorous health and symmetry of all under his care.

"Your Committee were glad to see that all the shrubs and trees were carefully labelled in bold characters,—except when the names of the plants were unknown, even to the eminent botanists before mentioned, thereby proving their great rarity,—thus enabling visitors to become acquainted with the different subjects cultivated, without trespassing on the time of the gardener. One specimen *Dacrydium cupressinum*, New Zealand Cypress, your Committee greatly admired. Nor are herbaceous plants neglected; *Mesembryanthemums* are here grown in large numbers, and stand the winter without protection.

"Mr. Beckford drew the attention of the Committee to a seedling Zonal Pelargonium, called 'La Chaire,' raised by him, which gives promise of being a valuable acquisition.

We will conclude with an extract from the Committee's summary:—

"Not only were the places visited remarkably well and carefully kept, showing evidence, too, of habitual good management; but throughout the island there were signs of taste and care observable, altogether wanting a few years back, which elicited the admiration of the strangers who joined the Committee.

"Where formerly, in front of many a farmhouse or cottage, was to be seen a patch of grass, rough with molehills and full of weeds, the pasture of a tethered cow or goat, was now found a well-mown lawn, ornamented with flower beds and shrubs. This betokens an improved

* Mr. Babington is the Author of a Channel Island Flora, entitled "Primitive Flora Sarum."

taste, an increasing love of horticulture, an appreciation of the beautiful, and a pleasure sought in refined and domestic ornamentation far less observable on the last occasion of a visit made by your Committee.

What has greatly contributed to this progress has been the introduction of variegated plants and shrubs, and of the bedding system of flower-garden arrangement. Not only was the progress evident in the ornamental part of the gardens, but the vegetable portions were cleaner, and showed unmistakable tokens of good management. The places open to inspection were undoubtedly the property of the older and leading horticulturists; yet it was evident to your Committee that their example was influencing the community for good, and there was no lack of imitation, not to say rivalry, in garden cultivation.

Your Committee must not fail to notice one garden, which for the judicious and beautiful combination of colours deserves great praise. It was not on their list for inspection, but the taste displayed in the arrangement of the lawn and the surrounding flower borders, induced your Committee to stop and notice it. Mr. F. Candia, the proprietor, had admirably disposed his Zonal Pelargoniums, Verbenas, and Calceolarias, whilst a simple line of white Pelargoniums, backed by a row of Golden Euonymus, running along a low wall, proved most effective.

Next, it is encouraging to notice how great are the returns of intelligent and systematic labour. Your Committee's attention was especially directed to this point. In many cases the results seemed extraordinary, when compared with the amount of wages expended in labour. Such are the effects of well-organised and systematic arrangement that comparatively large gardens can be and are kept in good order by the proprietor with the occasional aid of a farm servant, producing surprising effects and most satisfactory results, when in the care of a painstaking horticulturist.

In an island in which limited incomes are the rule, it was gratifying to find how much was done at a small outlay, and to this your Committee wish particularly to call attention, as a means of encouraging, as a recreation, a more general devotion to horticultural pursuits and tastes.

One pleasing feature noticed by your Committee was the long connection, in many cases, between proprietors and their gardeners, cases of thirty years, twenty-one years, fifteen years, and eight years service; nor was there any observable relaxation on the part of the gardeners in the endeavour to do their duty to their employers; on the contrary—it seemed to have created as great an interest in the well-doing of the place under their charge as could possibly be felt by the proprietor.

It particularly struck your Committee, and it is a well-known fact among the members of the Society, that wherever the gardener is "encouraged" to exhibit, a spirit of wholesome rivalry is engendered, the effects of which, as a rule, are manifest throughout the whole of his work. Your Committee failed to notice that there was a lack of attention in any one department, or that one object was attained to the detriment of another.

The effects produced by the judicious combination and contrast of colour, whether in the leaf or flower, was most noteworthy, the two most striking instances of this were the one at the Misses Ange's, the other at Trinity Manor.

The wall fruit with the exception of that at the Misses Ange's and Colonel Le Conteur's, was very much below the average. Indeed, it may be said, with few exceptions, that it is a failure this season; on the other hand, the Pear and Apple crop promises to be a plentiful one.

The Committee noticed with much regret, that the mildew on the Grapes showed signs of having been very prevalent, owing, in most instances to the presence of plants in the greenhouse. Still, your Committee think this is not a necessary adjunct to the growth of plants in the vinery, and that it may be avoided by adopting judicious treatment, and suggest the timely application of artificial heat, as soon as there appear indications of the disease, admitting air freely on all favorable occasions. It is stated by a gentleman of much experience in the cultivation of this fruit, that if the plants are turned out for a few days whilst the froit is stoning, and heat supplied as above directed, that the disease may be entirely prevented, without the necessity of having recourse to sulphur, which, as frequently applied, does much injury to the Vines, by choking up the pores of the leaves. It is perhaps needless to remind growers that drought, insufficient nourishment at the root, and over-cropping, are predisposing causes of this disease.

In the Vegetable department there was much to admire, both as regards the varieties cultivated and the high state of perfection to which they were grown. Here the progress was very marked, and it is evident that the periodical Shows held by the Society, have most notably, but surely, attained the object the Society had in view—viz.: the encouragement of the cultivation of such newly introduced varieties as were marked improvements upon the older ones; some of the indirect results being the abundant and beautiful daily supply to be seen in our local markets, and the yearly increasing exports to the English markets. The rotation of crops was, in most instances, rigidly attended to.

This leads to the consideration of a topic which cannot be overlooked by your Committee—viz., the growth and return during the past season of the early Potato crop. In one instance which has come under their notice, the yield has been six tons per acre, and has sold

for £25 per ton, giving a total return of £150 per acre. Besides the availability of the land for a second crop. On making inquiries, your Committee learnt that the total quantity exported during the past season has amounted to 3920 tons, which at £8, would give a return of £31,360 from this branch of island produce alone. This crop, though not heavy, is quite an average one, and with the high price realised, may be said to have given good returns for outlay. But it is feared the store varieties will prove much diseased and yield a poor crop."

TIME FOR STARTING VINES.

A HAS a vinery planted with Vines, from pots, in May last, in a border in the centre of the house, one Vine up the rafter, and the other down. The Vines are chiefly Muscats. They grew very well, but, of course, ripened off quite late (November). Well, A is advised by B to start these Vines early this season by the assistance of artificial heat. C recommends quite the opposite, he says that the Vines ought to start "of their own sweet will." Between the two opinions A is bothered, and would be obliged to the Editors if they would decide for him.—X.

[We agree thoroughly with C, and as the Vines ripened their wood late, we would let them start almost naturally, and then encourage growth and early ripening, so as to start earlier in 1869.]

CUPRESSUS MACROCARPA AND OTHER CONIFERS.

As Mr. Robson has asked for accounts of *Cupressus macrocarpa*, I am tempted to tell you what my experience has been here. Two plants in strong, but well drained clay, near a brook, were killed root and branch in the spring of 1867. Three on higher ground, in loam, Kentish rag lying beneath, were untouched. In this case I think we may attribute the cause of death to the clay, and the damp rising from the water. *Cupressus Udeana* in this same low ground is unhurt.

Some years ago I planted two trees of *Taxodium semper-virens*, one in fairly dry ground, the second in soil so wet that the hole had to be kept open by spades till the tree was planted. The second grew feet, while the first grew inches, and the case is still the same, only in a minor degree. I give you underneath the dimensions of my best Wellingtonia. Height, 27 feet 2 inches; girth of stem at about 1 inch from the ground, 6 feet 10 inches; circumference of branches, 43 feet 6 inches.—J. RIDGWAY, Fairlawn, Tonbridge.

SHREWSBURY'S NONPAREIL GAS-HEATING APPARATUS.

WHEREVER gas can be obtained as the source of heat, this is the simplest and most efficient mode of heating that we have yet seen. For entrance halls, conservatories, greenhouses, offices, harness rooms, and elsewhere it is most applicable, for when not required for heating purposes it may be removed until the cold season returns. Several of these apparatuses would heat a large conservatory or a church, and would be more desirable than more expensive methods of heating.

The apparatus is a boiler with a flow pipe into a pedestal tank, and a return pipe from this to the boiler; the whole less than 5 feet long, 2 feet high, and 8 inches wide. They can be had, however, of larger dimensions.

The gas furnace and the actual boiler are enclosed in a stout sheet iron case, and the gas flames are so disposed that their heat is profitably expended in raising the temperature of the water, and cannot act directly on the outer case or on the pipe through which the products of combustion are conveyed; consequently the external parts of the contrivance never get too hot.

The boiler itself is cylindrical, and has a tube or several tubes running through it. These tubes are bottle-shaped, wide below and contracted above. The boiler and its tubes are of cast iron. The gas-burners are placed directly under the bottle-shaped tubes, so that the greater part of the heat must be expended in raising the temperature of the water surrounding these tubes. To prevent any serious loss of heat by the

* "A second instance has been reported to your Committee, in which fifty perches of land have returned £70. This last is almost incredible, but seems well authenticated. The variety cultivated was the Early Fluke (a fixed sport from the old Fluke)."

escape of the hot air through the contracted orifices of the tubes, a separate case containing non-conducting materials is fitted above the boiler. The amount of heat that cludes this ingenious trap is so small that the pipe provided for the escape of the products of combustion never becomes unpleasantly hot.

The burners are constructed on the principle of the Bunsen burner, and give perfectly smokeless and intensely hot flames. Unlike the ordinary air-burner, however, Mr. Shrewsbury's patent burner requires no attention, and always gives a pure blue flame, free from any unpleasant smell. The holes for admitting air at the bottom of the burner are so constructed that the gas cannot be ignited in the tube by holding a light close to these holes. The burners are screwed into a flat gas-tight iron box at equal distances from the supply pipe, so that there is the same pressure of gas in each burner. This gas box is an important part of Mr. Shrewsbury's invention, for when several burners are fixed in a coil of tube in the ordinary way they necessarily give flames of different magnitudes. The box, with its burners, is made to turn on a swivel, and swing out of the door in the outer case for the convenience of lighting. Some of the larger boilers have six tubes, and as many burners, or groups of burners. The smallest size has only one tube. With such an apparatus an equable temperature can be kept up in a conservatory or room at the cost of about 3d. a-day for gas.

We have one in our outer office, where it may be seen in operation.

HEATING APPARATUS.

A CHEAP and efficient mode of heating is so useful to gardeners, that I was much pleased with the description of the Arnott's stove (in page 27), more especially as its powers have been brought to the test of experience.

Some years ago I heated an orchard house with a brick Arnott's stove, and, as regards economy of fuel, no contrivance could have been more frugal. Had the house been employed as a vinery, with the plants trained under the glass, it would, probably, have remained to the present day; but as it was devoted to Peach and Fig trees in pots, it was found that the stove took up too much space, and I was desirous of a mode of warming which would afford bottom heat. Mr. C. W. Martin, M.P., had then published the account of his revival of the Roman hypocaust, and it appeared to me that an arched flue under the border would be better still. A flue was thus constructed in my house, and the border made level with cinders. A long account of this flue, with diagrams, was published in the *Gardeners' Chronicle* of the 20th of May, 1865, to which, as also to the preliminary article of the 13th of the same month, I beg to refer such of your readers as may be desirous of learning further particulars.

The subsequent experience of three years has not modified the favourable opinion I had then formed; but if I were about to build another flue I would make it a few inches deeper, in order that the sweep might have more room to turn himself about; and if the small escape of heat, which, undoubtedly, takes place through the outer wall, be thought important, this could be remedied by making the arch of the flue spring from an internal wall built for the purpose, instead of making it spring, as at present, from the external wall; and if a few inches were left between the two walls, all escape of heat would be prevented, and the direct flue might run under the front border, and the return under the back one.—G. S.

THE ROYAL ASCOT GRAPE.

WE have on several previous occasions drawn the notice of our readers to this new Grape, and have spoken of it in the highest terms as being one perfectly distinct from every other early Grape, and possessing a richness of flavour which is not found in any early variety except itself. Our present object in noticing the Royal Ascot, is to introduce a new character it possesses, and as this is one which adds greatly to its value, it is desirable it should have the greatest publicity. As we have witnessed the facts we are about to relate, we speak with the most perfect confidence. This new character it has shown is its great prolificacy, and its pertinacity in keeping up a succession of fruit without going to rest. There is in Italy an insignificant little Grape grown under the name of "Uva di tri volte," the bunch and berries of which are not bigger than the Black Cluster, and which possesses this same property, so that by stopping the shoot two or three joints beyond the last bunch, just as the flower has fallen and the berries are set, it

may be made to produce three crops in the year. The Royal Ascot, unlike the little Italian variety, has bunches and berries as large and handsome as those of the Black Hamburgh, and the vigour of the Vine is unusually great.

The Vines that produced the new Grapes shown at the last meeting of the Fruit Committee, were not more than a foot high, and turned out of 5-inch pots in the first week of May last, being planted out in a Pine stove 18 feet wide, with a span-roof, and a 3-foot path up the centre. Mr. Standish states, "It was at the front of this house, on each side, that I put a little soil kept up by a dry 4½-inch wall of bricks. At the back of this were Pine plants plunged in dung and leaves. The Vines grew very rapidly, and soon got to the top of the house, about 12 feet. They were then topped, and about the middle of August they threw out bunches all down the Vines. At first we plucked these off, but they came thicker and faster from the young growing wood. At last, about the middle of September, I left from four to six bunches on six plants, and although they were grown under such adverse circumstances, I send you a bunch to form your own opinion, and judge what the Vine is capable of doing under better culture. Just as the Vines set their fruit I found that their roots were out in the plunging material, where the Pines were growing. I thought as they must be moved, the sooner this was done the better, so they were taken up and laid into another lot of soil, but there was such a quantity of roots that the leaves on the young Vines flagged. So you see they had a rough time of it."

As a Vine for winter work it is unequalled.

HENDERSON'S CONQUEROR CELERY.

I BELIEVE this distinct variety of Celery was first issued to the public by the Messrs. A. Henderson, and after two years' experience with it, I am of opinion that it is the best white variety in cultivation. I have not formed this opinion hastily, for, having to grow Celery largely, I have tried all the white varieties I could procure, and I do not hesitate to recommend this sort to all those who require Celery of a superior description, and particularly for early sowing to come in for late summer and early autumn use.

I have proved that when sown in heat in January, and grown on without receiving a check, not 1 per cent. will run to seed.

It is distinct from other white varieties in being more branching in habit, and having a rich green and rather curly foliage. It is also a rapid and robust grower, with solid, yet very tender, leaf stalks, so brittle that the stalk can scarcely bear the weight of its leaves; it blanches so well that every stalk is fit for use, and of a pearly white colour. It has a nice walnut flavour, and is remarkably crisp.—THOMAS RECORD, *Lillesden, Hawkhurst.*

CATERPILLARS ON BEDDING AND OTHER PLANTS.

I FORWARD for your inspection a caterpillar which I have found by hundreds on my young stock of Pelargoniums, Verbenas, Calceolarias (shrubby and herbaceous), Cinerarias, and Primulas. A short time ago I was induced to look very closely into my boxes of bedding plants, the foliage becoming nearly perforated all over. I at once set to work to hunt for slugs, which I thought to find, but to my astonishment it was a large green caterpillar, which I discovered in myriads. I am glad to say I caught them in their early state of working, otherwise I do not know what the consequences would have been.—R. E., *Womersley Park, Yorkshire.*

[The caterpillars were crushed by the post office punches. The portions uncrushed were like the larva of the Brimstone Butterfly. The eggs must have been deposited late last year; and hatched early by the warmth of the house.]

PEAT CHARCOAL.

As a constant reader of your Journal, I see and have before replied to inquiries on peat charcoal. "T. C." wishes it for Hays's patent stove. It was manufactured near Carlisle (twelve miles from it), for some years, but from mismanagement did not succeed as a manure. The Company (now guaranteed), have discontinued to make it. The mode of calcining it is troublesome and expensive. The peat has to be placed in an iron vessel enclosed in a brick arch, with a flue throwing a blaze around it. There is a receptacle at the bottom, with a pipe

for discharging, to separate the grease from the peat before it will calcine. The cover of the iron vessel must have a double rim, to be filled at top with water to keep it air-tight. The most likely place now to procure peat charcoal will be in Dublin. Write to Mr. J. Smithson, Messrs. Goulding's Manure Manufactory, Dublin. If particulars are required for manufacturing, I shall be happy to afford them in detail.—H. ORMAN, *Griusdale Manure Works, Carlisle*.

LEEDS PROFESSIONAL GARDENERS' FRIENDLY BENEFIT SOCIETY.

SOME time ago the advisability of establishing a gardeners' friendly benefit society met with several advocates in the columns of the Journal. It also received the support of the Editors, who kindly took the trouble to publish a code of rules for the guidance of such societies; notwithstanding which, the project fell through. The want of such a society has long been felt in this neighbourhood, and to meet it several of the leading gardeners around here met and adopted the necessary measures towards establishing one, and drew up for its guidance the rules I herewith beg to forward you.

I scarcely expect that the rules will have your entire approval, for, in the first place, they do not conform to a graduated scale of contribution, as insisted on in your code. That important matter, I believe, received due consideration at the formation of the society; but the conclusion came to was, that as the society was to consist entirely of professional gardeners, and the majority of the older members being head gardeners whose wages are very rarely stopped during temporary sickness, they would not, therefore, relatively be so likely to apply to the society for assistance as the younger members, the majority of whom are under gardeners who have not generally the same consideration shown them by their employers. The society is now having some proof of the soundness of the above reasoning. There are at the present time three or four members sick who might lay a just claim for assistance; but only one who is an under gardener has the necessity to do so, and his is a case of extreme prostration. Whilst, therefore, admitting the equity of a graduated scale in almost all other benefit societies, ours has some cause to show why it should be an exception.

Some of the above reasons also apply as regards our rates of contribution being fixed lower than with most other societies. An additional one is, that we shall have a much larger proportion of honorary members. We already have nearly 10 per cent. of such without having made any solicitation; but when, as we intend doing soon, we bring the objects of the society before the notice of our employers and others, and solicit their support, we have every confidence of meeting with a very liberal response from them.

It has been thought advisable to alter Rule 24, so as to admit younger members. Originally members were not admitted under twenty-one years of age, and they were required to sign a declaration that they had worked five years successively as a gardener; whereas now members are admitted at eighteen years of age, providing they can affirm that they have worked three years in the capacity of a gardener.

I also wish to call attention to the rule which gives members the privilege of bringing any extraordinary flowers, fruits, or vegetables before the President, who submits them to the notice of the meeting, and invites any remarks or discussion thereon. We have found it greatly to enhance the pleasure and instruction to be derived from attending the meetings of the society.

It is also proposed to invite members to contribute short papers or essays on subjects connected with our profession, and to read them at our meetings after the usual business belonging to the society has been transacted. By so doing it is hoped that some inducement will be afforded young men to join, partly for the instruction to be gained therefrom. To all of us it will make the meetings more interesting, and tend to make the society a worthy one, around which all may rally, and from which shall emanate both help to the aged and afflicted, and pleasure and instruction to the young and strong.

The society has now been established a little over twelve months, and the first annual dinner was held on the 15th inst. at the Leopard Inn, Briggate. A very large number of the members were present. Mr. M. Daynes presided, and the vice-chair was occupied by myself. "Success to the Society" was proposed; and the Secretary, Mr. W. Sunley, in responding, stated that the Association was formed in 1867, and that the rules

were passed and registered under the Friendly Society's Act in March of that year. Each member paid 3d. per week, and in sickness received 10s. per week for half a year, and 5s. for the remainder of his illness. At the death of a member £10 were paid over to his widow or relatives, and on the decease of the wife of a member £7 were paid over. A levy of 1s. each is made at the death of a member, and of 6d. each at the death of a member's wife, towards the funeral allowance. When the society commenced there were 76 members, and at present the number was 103, exclusive of six of the honorary class. The funds had a balance of £51 9s. 4d. now at the credit of the society.—R. FEATHERSTONE.

BROCCOLIS MALFORMED AND NOT TRUE.

SOMETHING appeared a short time ago in the Journal about the malformation of Winter Broccoli, I am sorry to have to complain of the same evil. Instead of having heads in the form of Cauliflowers, a great many of mine have degenerated into a kind of branching Broccoli, not equal to Lee's White Sprouting. Now, this is very provoking after being at the expense of seed, labour, and land, to say nothing of the disappointment, and it is not the case only with Snow's Winter White and Backhouse's Winter Protecting, but with other kinds as well.

I am beginning to think that the Broccoli tribe is fast degenerating. Often from an ounce of seed I can scarcely see half a dozen plants alike. I think these diversities ought not to be. When I order a certain kind of Broccoli, I am inclined to think that I ought to have something like what I order, and what its name implies. There must be a fault somewhere, but where it lies is not for me to say; whether it is with the grower, the importer, or the seedsman, I am not prepared to decide. The seedsman must sell such as he buys, the grower must sell such as he grows, and the importer such as he imports.

When I was a youth we could procure Miller's Dwarf Broccoli and Dwarf Russian Broccoli something like themselves—little compact subjects about 1 foot in height when grown on a north border, and ready for cutting in April and May, but now they, though called by the same name, reach much nearer the sun. Perhaps they are called the "Improved!"

I am afraid that I must say to the original of the above "farewell." For sixteen years I have tried, but tried in vain, to procure Miller's Dwarf as it was twenty-five years ago. I have a kind sent bearing the name, but that is all; what should have been Miller's Dwarf, has merged into some giant form, and I am as usual doomed to disappointment. It is time that some one came to the rescue.—M. R., *Acklam Hall, Middlesbrough-on-Tees*.

NOTES AND GLEANINGS.

THE PROPRIETORS OF THE JOURNAL OF HORTICULTURE have determined on offering at the ROYAL HORTICULTURAL SOCIETY'S SHOW, at LEICESTER, to be held on July 16th and following days, Special Prizes of the same value and for the same subjects as they did last year at the Bury St. Edmund's Show—viz., Two First Prizes of the value of Ten Guineas each for the two best Desserts, consisting of not less than Seven kinds of Fruits of 1868, arranged as for the table, combining Quality of Fruit with Taste of Arrangement. These prizes are to be competed for by Gentlemen's Gardeners and Amateurs only, and but one prize to be taken by the same person.

CORDON TRAINING.

(Continued from page 73.)

Fig. 5 is from a photograph of an upright trained tree, with five vertical cordons springing from a common base. Trees may be purchased already trained in this form, but the double horizontal cordon may at pleasure be changed into this form by selecting strong shoots at regular intervals, fastening them to stout stakes, and summer-pinching them as practised for oblique cordons. No central stem should be permitted in an upright trained cordon; it will absorb an unfair proportion of the strength of the tree.

Fig. 6 is a fan cordon, and the advantage of the simple method of summer-pinching will at once be seen. Instead of a wall being perforated all over with nails, a few only are

required to fasten the shoots selected for cordons. This form may consist of five, seven, or more cordons. The symmetry of the tree should be the point most strictly attended to, a sym-

metrical tree being more pleasing to the eye than one irregularly shaped. The same method of pruning is required as for oblique cordons.

Fig. 5.

Fig. 7.

Fan cordons can be managed by an unscientific gardener, but to produce one well shaped on the usual plan requires a skilful and practised hand. It is possible that in the northern and westerly districts Peach and Nectarine trees will produce

too many unripened spurs, but probably by attention and strict thinning this difficulty will be surmounted. Plums, Pears, Apples, Apricots, and Cherries are all amenable, and no hesitation need be felt in subjecting them to summer-pinch.

Fig. 6.

Fig. 7 is a double oblique cordon, formed by cutting down the dwarf tree to two buds, and proceeding as for oblique cordons.

Fig. 8 represents a compound horizontal cordon. This

should have a central shoot and branches trained from it as nearly opposite as possible. This system has long been used for Pears and Apples, but not so generally for stone fruits.

It is well adapted for Peaches, Nectarines, Apricots, Cherries, and Plums. All of these may be trained as compound horizontal cordons in the colder climate of Yorkshire.

A very skilful cultivator of fruit has trained Peaches and Nectarines with complete success, to counteract the tendency of these fruit trees to produce much unripened wood. When under cordon training he leaves on every branch a shoot which he calls an exhauster. This shoot forms an outlet for the superfluous energy of the tree; and the fruit spurs, being deprived of the superabundance of the vital fluid, do not break into growth. This theory will be found to be very sound practice, and should be used wherever there is a tendency on the part of the tree to produce many unripened spurs. This mode of training for

the Pear and Apple is already well known; and when applied to Peach and Nectarine trees, the only deviation from established practice will be to treat every horizontal branch as a cordon, and to practise summer-pinching instead of allowing gross upright shoots to be made.

Fig. 8.

Fig. 9.

Fig. 9 is a single vertical cordon in a pot, and if an orchard house or glass shed is available these will be found very useful and interesting trees. Pear, Apple, Cherry, and Plum trees may be potted into 8 or 10-inch pots, and moved into a glass shed, or, indeed, any shed open to the sun, while in bloom, and kept under cover until all danger from spring frost is past. They should then be removed to a border prepared for them—the warmer and more sheltered the better. The pots must be plunged to within 2 or 3 inches of the rim. Stable litter partly decomposed should then be spread over the pots and the soil; and as these trees will require watering, they should be placed near water. One-year-old dwarf trees may be bought at a cheap rate and potted. The fruit will be produced in the second year after potting. The soil for the trees should consist of good, strong, calcareous loam mixed with a third of its bulk of decomposed manure. An old Cucumber or Melon bed may be used; or, if not convenient, stable manure thrown up and fermented for some time will answer very well. The soil must in all cases be made very firm and solid in the pot. The border or bed for their summer quarters should be 6 feet wide;

this will take four rows of trees. This distance is perhaps the most convenient for pruning and watering, but it may be increased or diminished at the will of the cultivator.

Under this system trees which appear to be walking sticks in the winter will become wonderfully fertile; and if protection in spring can be afforded the crop is almost certain. As it is possible and probable that during the summer some of the roots will have passed through the bottom of the pots into the soil beneath, it will be necessary, after the fruit is gathered and the trees are at rest, to detach them from their anchorage by taking up the pots and cutting off all the roots that protrude through the drainage hole of the pot. As this operation will break up the summer quarters of the trees, there will be no necessity to replace them at the distance requisite for their summer cultivation. They may be much more closely packed for their winter quarters, plunging them as mentioned before, and during winter covering the pots thickly with straw or stable litter. In this position they may be left without any further care or attention until the returning spring urges them again into fresh activity and fruitfulness.—T. FRANCIS RIVERS.

WORK FOR THE WEEK.

KITCHEN GARDEN.

The general preparation of the ground for the spring crops having been delayed later than usual, no time should be lost in forwarding the necessary digging and trenching, preparatory to a more thorough manipulation of the soil before sowing. The principal causes of success in growing vegetables are a fine tilth, and as great a depth of earth as can be obtained without interfering with the subsoil, if the latter is of a sour nature. Clayey and retentive subsoils should, however, be forked over, loosening the ground for some depth. This will facilitate the passage of water from the roots, and by degrees the subsoil will become improved. There are but few vegetables that do not require a medium depth of 2 feet to grow in, some more, and hence the necessity of deep, well-pulverised soil for their successful cultivation. For the present the dung may be dug in as trenching

goes on, and its thorough incorporation with the soil will be best effected when the ground is again worked over with a three-pronged fork. It is now necessary to determine what the different quarters of the garden shall be filled with during the season. Though one vegetable may be grown on the same ground for years, yet such a method involves a greater expense for manure and labour than when a regular system of rotation is adopted, as the culture of one vegetable often prepares the soil for the growth of another. The chief rule to be observed with all annual vegetables, is never to have two crops of the same class directly following each other. Though excellent plans of rotation may be laid down, yet the period that will elapse before the ground is again occupied by a similar crop, will depend upon the wants of the establishment, and the extent of ground at the disposal of the gardener. *Garlic* should

be planted: also *Shallots*, in rich ground, in drills 1 inch deep, and 6 inches apart every way. To prevent the attacks of maggots it is recommended, when digging, to mix a good sprinkling of salt and soot, or wood ashes, with the soil; or, if any signs of maggots appear, water with soot dissolved in water, the soot to be put in the bottom of the tub, a little water to be added, and then stir the whole well, and fill up with water. The liquid will settle in a few hours, when the top should be skimmed off, and the rest will be fit for use. When hoeing draw the earth away from instead of towards the bulbs, to prevent the attacks of mildew. Slacked lime strewed along the rows will prevent the worms from drawing the bulbs out of their places. *Potatoes*, plant Ash-leaf Kidneys on a bank or border sloping to the south, or at the foot of a south wall or hedge. The middle-sized whole Potatoes should be planted 9 inches apart in the row, and covered with 4 inches of soil. When they appear above ground they should be protected with straw or litter every night until all danger of frost is over.

FRUIT GARDEN.

If any fruit trees still remain not pruned, it is not yet too late to perform that operation, taking care to keep the branches thin and regular. When Peach and Apricot trees are just ready to open their blossoms, you must be ready, too, with a wash composed of lime, soot, sulphur, and soft soap, to paint the trees all over. The later this is done the better. For the other trees, on the walls, or in the orchard, six weeks hence will be time enough to wash them; but for those on which you have noticed any red spider for the last season or two, you must mix a portion of sulphur with the soot and lime.

FLOWER GARDEN.

In gardens where the ground was thrown up roughly in the autumn, it will by this time be pretty well mellowed, and, therefore, if the weather is dry it would be well to dig the beds over again, so as to bring some more of the soil under the direct action of the atmosphere. When the ground is poor enrich it by adding some fresh compost, such as leaf soil, peat, and loam mixed together, but avoid fresh stimulating manures, or you will have strong, rampant plants at the expense of a fine show of flowers. A few days might be advantageously spent in regulating shrubs, such as tying misshapen plants into good forms, pegging down branches to cover the naked ground, and planting a few evergreen trailing plants where such are necessary. Examine landscape scenery, and see whether by taking down a tree here and there, or lopping a few branches, you cannot let in a distant object or two that may be worth seeing. As the time is rapidly drawing on for potting Carnations, look well to your compost heaps, turn them over, and particularly in frosts. Examine your turfy loam, break all lumps with the back of the spade, and destroy every wireworm you see. It is lad economy to be negligent in paying attention to your soil, as a single insect of this description will often destroy Carnations to a serious extent if overlooked. Should a frost ensue, gather cow manure from the pastures, and pile it in heaps to decompose. All vegetable refuse ought to be collected whenever an opportunity offers.

GREENHOUSE AND CONSERVATORY.

Established plants in the conservatory should about this time have the soil well stirred at the tops of the pots. The surface of the border should now be removed altogether, the soil stirred with a fork a few inches deep, and a layer of fresh earth put on; more air should be given for the first week after the operation to sweeten the house. Fast-growing climbers that exhaust the soil in a few years and become stunted, ought to be transplanted now into fresh soil. As large quantities of air are admitted to the greenhouse, more attention to watering is necessary. Many greenhouse plants would be much benefited if they could now be turned out into cold pits where frost could be kept from them. Our long nights are not favourable to very early spring growth; indeed, nothing can be more injurious to many woody plants than to allow or encourage them to grow early. Softwooded plants that are annually cut down or close-pruned, do not suffer so much from growing out of season.

STOVE.

Any plants that flower in winter are valuable. *Clerodendron splendens*, *Centradenia rosea*, and *Manettia bicolor*, are of this class. The *Manettia* requires less heat than the other two. They will do well in an intermediate house, and flower freely in a conservatory with 45° of heat. *Dendrobiums* which had their shoots well ripened last autumn, will soon be beginning to bloom; some of them might now be forced, and others removed

to a cold place and kept dry, in order to prolong their flowering season. *Maxillaria aromatica* ought to be grown largely for forcing, it is one of the easiest Orchids to cultivate. A few *Stanhopias* might also now be forced. All of these plants that have been kept dry through the winter, should be plunged in tepid water to soak the moss, peat, &c., in which they are grown, preparatory to regular watering. It is yet too soon to encourage plants in general to grow; many would be benefited by a layer of fresh soil or top-dressing. Give air freely on fine sunny days.

FORCING PIT.

There is considerable room for speculating on the causes which render plants liable to the attacks of insects. In the forcing pit we see hardy plants infested on which an insect is never seen in the open air. Moist heat being essential for this pit, less watering is needed. Over-watering is a frequent cause of failure in hardy plants, and a dry atmosphere and sudden changes are nearly as bad. *Pimulas*, *Auriculas*, *Anemones*, *Pionies*, and almost all plants that flower in April, May, and June, out of doors, will force and flower two months earlier if not put into too much heat at first. The whole race of papilionaceous plants will force with less risk than other tribes.

PITS AND FRAMES.

Scarlet and other *Pelargoniums* planted out in pits for the winter may be potted and placed in a little heat. The first opportunity make up a gentle dung bed for a propagating frame.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Asparagus.—Just now we like an *Asparagus* frame to have the woodwork at the back and ends white, and the glass clean, to let the shoots have all the light possible. There is no chance of the sun being so bright for a month or two, as to injure anything by the light and heat reflected from a white surface. We are obliged to deaden the white colour on many walls in summer, but it is scarcely possible to have walls where plants are growing too white in winter, as the rays of the sun are in general too oblique for their light and heat to be reflected powerfully. Hence clean glass is of more importance in winter than in summer, when a little shade is often an advantage. Our forced vegetables we have merely kept succeeding each other.

Rhubarb.—We are glad that "Yorkshire" has it so good close to his kitchen fire. It is many years since we told how a clergyman used to give treats to the ailing of his flock by resorting to similar means. Nothing suits better for the purpose than an old barrel of convenient size for removal, packing the Rhubarb roots in the bottom, in soil, giving a good watering out of doors, and covering with an old cloth if there is not a lid. Wherever a heat of 50° to 55° can be secured, Rhubarb can be had all the winter after Christmas. It does not come so well when taken up before December. If the roots become too dry the barrel may be rolled outside, watered, and when drained brought in again, without causing dirt. We would be afraid to mention the number of stalks taken out of a barrel 30 inches in height and 15 inches in diameter, and it should not be forgotten that Rhubarb thus forced will be better when from 12 to 15 inches in length than when of longer growth. There are few who have a garden and Rhubarb roots in it, but may thus have a tart in winter and spring if they like. If desired, the roots when done with may be divided and planted, and according to the treatment given they will be fit to be taken up to force again in two or three years.

Sea-kale may be grown in a similar way, and in boxes or barrels 18 inches deep. Nothing is easier to grow in summer; and young seedlings a year or two old, planted in rows 9 inches apart, and 18 inches from row to row, would be in a fine state for taking up after the beginning of November. We would prefer boxes for this purpose, adopting the same treatment as for Rhubarb, but keeping dark, and cutting the heads when from 6 to 7 inches long. We have filled a 12-inch pot with roots, leaving the crowns level with the rim, and covered with another pot of a similar size, closing up the hole, and tying a piece of list round where the two pots joined, and from that pot obtained two good dishes, or three middling ones, without counting on a second gathering of smaller shoots. Not to speak of many manufactories, there are often recesses near fire-places where such pots or boxes could be placed, and thus a great delicacy and luxury could be obtained at little trouble,

and hardly any expense. If only gathered from once, or partly twice, the roots will be useful for planting again; but if allowed to produce a forest of small shoots, the roots will be of no further use, but should be thrown away when done with. Sea-kale, like Rhubarb, is easily obtained over hotbeds in Mushroom houses—anywhere, in fact, where the heat, from 50 to 60°, would bring it on; but it is well to note that it can also be had in good condition wherever there is a garden to get the roots from, and a fireplace near which they may be placed. After the end of March we have seen fine pearly white Sea-kale in a dark cellar. With the dung necessary for a small Mushroom bed in such a cellar, we have started Sea-kale in pots before the dung was mild enough for spawning.

In the open ground, trenching, ridging, &c., was proceeded with in suitable weather, and a piece of ground was prepared for Peas and Celery, following after Parsnips, Carrots, &c., the ground being laid out in 5-foot and 4-foot widths; the 5-foot spaces being well dug, and the 4-foot spaces being made into bed trenches, by throwing a good spit from them on the 5-foot ridges. These ridges will have the second crop of Peas along the centre, Radishes and Spinach at the sides; and the trenches, before the Celery is ready, will come in for bedding plants, Lettuces, and Potatoes. A little shade from the Peas will do much good to the Celery.

FRUIT GARDEN.

Proceeded with pruning out of doors, and will follow with lime-syringing to keep the birds away. The lime also tends to keep the bark clean and free from moss and lichens. Covered a Vine border with about a foot of fermenting material, 6 inches next the soil being hot. This border had merely a few inches of litter to keep out the frost previously. We would have given a little heat earlier but for being short of material. We would also have kept the heavy rains off, but had not covers; but when a border is well drained the water soon passes away, and if a little litter is put on, it acts so far as thatching. Covered also the border of a Peach house with a few inches of litter, as the trees are beginning to move, not to give heat to the soil, but to prevent it being cooled. A slight sprinkling was over the border all the winter, enough to prevent frost affecting it much, if at all. A very little on the ground keeps heat in and cold out. Even Strawberry plants and tender subjects in pots out of doors, although unplunged, will not be injured if a little litter or clean straw is laid over them, so as to leave no openings. Even Vines with roots entirely out of doors, and near the surface too, may be forced tolerably early; and there will be no want of a mutual, correlative action between roots and branches if, without throwing any heat into the soil of the outside border, from 6 to 12 inches of dry litter has been placed over it in the end of October to prevent the heat accumulated in summer radiating from it in winter. In such a case it is as well to let the litter extend beyond the border some feet. One advantage of this plan of conserving heat is that there is no danger of doing any injury by extra heat from fermenting material.

When it is intended to grow Vines in pots from single buds, no time should be lost in having them placed singly in small pots, and then set in a sweet hotbed. The advantage of the single pot is that no injury or check is given to the roots when shifting into larger pots; and growing these buds now into strong-enough canes to fruit early in 1869 depends on growing them on, placing them early this season in their fruiting pots, and ripening the wood early.

Strawberries.—The weather has been dark for early Strawberries. Those coming on must be carefully watered, so as not to be long dry nor wet. No water must ever stand in the saucers until the fruit is swelling, and even then it is not advisable. For beginners it will be better to set the plants in reversed turf, on moss, or anything that will keep a little moisture at the bottom of the pots, and yet prevent moisture standing there. If the soil become very dry the fruit buds will be dried-up and decay; if the soil be kept moist, so as to partake at all of the character of a morass, the buds will rot from an opposite cause. After March shall have come there will be less occasion for being so very particular; but for want of such care in early forcing many plants become blind that otherwise would have produced a good crop. For somewhat similar causes those plants brought on now, plunged in a little bottom heat in pits and frames, must be prevented rooting through the pots. If the heat below is strong, and the roots much encouraged in the plunging material, there will be too much encouragement to mere growth, and the leaves will be so liable to excessive growth, that the flower trusses will be

left behind and come to nothing. This is chiefly of importance in early work, and the rooting-below is of less consequence after the trusses have come boldly, and have opened their blooms. They would then be more independent of particular watering. Rooting through the pots in a hotbed should be avoided in early forcing.—R. F.

COVENT GARDEN MARKET.—JANUARY 30.

We have no change worth notice in our quotations this week. French salading is much improved.

FRUIT.

TRADE CATALOGUES RECEIVED.

Downie, Laird, & Laing, Stanstead Park, Forest Hill, London, S.E., and 17, Frederick Street, Edinburgh.—*Catalogue of Garden, Flower, and Agricultural Seeds, &c.*

Hooper & Co., Covent Garden Market, London.—*General Catalogue.*

F. & A. Dickson & Sons, 104, Eastgate Street, Chester.—*Catalogue of Vegetable and Flower Seeds.*

T. Bunyard & Sons, Maidstone, Kent.—*Catalogue of Vegetable, Flower, and Agricultural Seeds.*

Wheeler & Sons, Gloucester, "Little Book," *Selected Seed List.*

TO CORRESPONDENTS.

*. We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

N.B.—Many questions must remain unanswered until next week.

VIOLETS (J. E.).—The Giant, Czar, and Queen are all single and all hardy.

DRAINING AN ORCHARD (Nob. Subscriber).—Three-inch pipes would be much less liable to choke than 1-inch pipes. Place them 3 feet below the surface. You may root-prune the trees at the same time if you drain now and the trees require the operation.

DRAINING CLAY LAND (E. M. L.).—As far as we can judge from scanty information, the best course for you to pursue would be to drain at intervals of 15 feet, and 5 feet deep, and to pare and burn 9 inches of the whole surface. Mix the manure with the burned clay, spread it, and plough it in. It ought to render the land fertile. If you send five postage stamps with your address, and order "Manures for the Money," you will have it sent free by post. It contains information of all the manures you name.

BATTERSEA PARK (L.).—We have no doubt the plant you mean is *Sempervivum californicum*, which is green tipped with reddish brown, and makes a first-rate edging.

GLADIOLUSES AND LILUM LANGHEIM (J. E.).—They may be sown in collections of herbaceous plants, although there are separate classes for these bulbs, unless there is a special offer to the contrary in the schedule of prices offered.

SALVIA ON THE COL DE TENDA.—Several correspondents suggest that it is *Salvia hermanni*, or Purple-topped Clary.

CYCLAMENS (Woolston).—If you enclose twelve postage stamps and order Nos. 297, 298, and 299 to be sent to you, you will find in them a full essay on the culture of Cyclamens.

SCALE INSECT ON CURRANT BUSHES (T. Garnett, Clitheroe).—The scale insect, with white woolly envelope over the eggs, is the Vine scale (*Coccus vitis*). We do not remember seeing it on the Currant before. Scrape away the rough bark, and paint all the stems with a creamy mixture of half a pound of soft soap and 1 lb. of flowers of sulphur, boiled for a few minutes in two gallons of water.

ROSES ON MANETTI STOCKS—MULCHING (J. G. R.).—"You had better not prune at all the Manetti-stocked Roses just planted, than cut them down to four or five eyes. Such short pruning usually causes them to push from the neck of the stock. They rarely send forth suckers from the roots. Thin out under-wood, cut the shoots to a good eye at the summit of the plants, and shorten the side branches a little to a good eye. Prune them at once, and place litter over their roots. This should have been done before. As soon as blooming is over I shorten my plants a little, and cut them pretty much as above. Sanders's Look on the Vine is published at the office of this Journal. The author was Mr. Ashton Smith's gardener. If you enclose 5s. 1d. in postage stamps with your address, you can have it free by post.—W. F. RADCLIFFE."

COST OF A PIT (E. R.).—Whether £5 would be too much or not for the building of your pit, would depend very much on the quality and size of the stones you used for walls 2 feet in height beneath the surface, and the thickness of the brick walls above the ground. At first sight the sum seems fair; but, then, much depends on these considerations. In all such matters, where the proprietor finds lime and stone, and clears out the ground, it would be better he found also the bricks, tiles for flue, &c., and then contracted for the mere workmanship; or, better still, had it done by day wages by a good workman. You will know better than the thickness of the walls, and if you calculate the expense of this you will easily see what is left for labour. In general, it rarely suits either party to have so much material provided, and the workman to find the rest and the labour. It is better to give no materials, or all, and in the last case contract for the labour, or, which would be as well in such a job, have it done by day wages.

STRAWBERRY LEAVES SPOTTED (G. Pine).—The leaves of your Strawberries are spotted by the frost and other ungenial weather. Those leaves will all decay, but fresh ones will come, and you need not trouble about them. It is just as natural for Strawberry leaves to become thus discoloured in winter as it is for an Oak leaf to turn yellow and fall. We hope that the leaves are old ones, as we believe them to be. If young leaves of this year in house, we should judge they had suffered from extremes of wet and dryness.

YELLOW BEDDING PLANT (Savannah's Winding Shore).—We do not think the half-hardy annual, *Venidium calendulaceum*, so good as *Gazania*. It belongs to much the same class, is orange in colour, and about 12 inches in height, but generally goes off in the autumn.

SETTING A SADDLE-BACK BOILER (W.).—If saddle-back boilers are small we like to set them 2 or 3 inches higher than the fire bars, or grating, on fire bricks or fire lumps, and we need to have a block of fire lump at the farther end, so that the fire should go over it at the top, come round the outside of the boiler, and then along the top to the smoke shaft; but, latterly, if the boilers were large we do not care about this leak-draught lump, but let the end of the furnace serve the purpose. One object is thus gained without a lump—there is no chance of a careless stoker choking-up the space or flue behind it. Terminal saddle-backs save all this trouble. We hardly know what you mean by hollow bars or burs. If you mean pipes for grating, they can only be used when connected with the boiler, and we do not think that they are of much advantage, as they present a coolish surface at the bottom to the fuel, and therefore there at least the combustion is less perfect. If by "burs" you mean fire lumps, we see no objection to their being hollow, though when the hollow was reached in wear they would be useless.

HEATING AND ARRANGING A GREENHOUSE (E. B.).—To do what you propose—namely, heat a propagating house, 8 feet long by 10½ feet wide, and a greenhouse adjoining, 12 feet by 21½ feet, by a flue, we would proceed as follows:—Having due regard to your doorways, so that the flue will not interfere with them, nor descend below them, at the north-west corner of the propagating house place the furnace and chimney, and take the flue along the end and front of the house and back again, which will give you heat enough there for a propagating bed, as alluded to in answer to "NOVICE" last week. This you can manage by a circular turn to the flue, but fitted with a damper, to be used when required. With the exception of this curve, which will enable you to heat the propagating house only, we would continue and return the flues straight, which will place them in the middle, or nearly so, of the greenhouse, and dampers in the flues there will enable you to let the heat in there when wanted. You should have a tank inside the house for rain water, with an overflow to a drain. The greenhouse will do admirably for Grapes; six Vines will do. Have a hipped stage in the middle, and a shelf all round for plants.

FURNACE OF A FLUE-HEATED GREENHOUSE (E. B.).—We do not think the furnace much too large if your furnace bars do not occupy a space more than 15 inches long by from 9 to 12 inches wide. If for such a small house you find the space is too large, then brick-up the farther end, merely leaving space above for the draught to pass into the flue. In a case similar to yours we advised a fire lump to be placed at the farther end of the furnace to lessen the bulk of the furnace fully one-third, and it answered perfectly.

HEATING A SMALL FORCING HOUSE (A Reader, B.).—In the forcing house, 20 feet by 9, and to force early, you will need for heating it from 60 to 80 feet of 4-inch pipes. A flue well made would cost you less at first, and less for fuel afterwards, but it will not be so safe and pleasant as hot water.

VINE BORDER FOR MUSCATS—WOOD FOR DRAINAGE, &c. (A Subscriber to the Journal).—The Muscats will keep well in winter without heat at the roots, and more especially as the border is inside the house. Wood and old roots do not do so well for drainage as stones, &c., as they are apt

to produce fungus. Why not use earthenware drain pipes? The old Vines outside will not interfere at all with the Muscats planted inside, if you give the Muscats light and room enough, and cut away the old Vines as the young ones become established. The Muscats would ripen and colour better if you had more glass, larger squares, and less timber and laps in the house.

LATE VINES—ROYAL ASCOT VINE (H. S.).—As a selection of the best late Vines, you cannot do better than take Muscat of Alexandria, Muscat Hamburgh, Lady Downe's, Alicante, West's St. Peter's, and Trebbiano. The Royal Ascot was exhibited at the Great Show at Bury St. Edmunds last summer, and obtained the first-class certificate of the Fruit Committee. You will also see notices of it in our report of the meeting of the Fruit Committee in our last number, and in another column to-day. It is a valuable Grape, particularly for "winter work."

FRUITING GRAPE VINES (E. A.).—If you grow young Vines strong and ripen the wood well, you may take a crop from them the following season; but in proportion to the crop taken you injure the Vines for ever afterwards. When you want to obtain a crop at once in your house, turn out well-grown canes from pots, and keep some in pots, and fruit these; but those you wish to have as permanent Vines, treat in the way recommended, and only take full crops after three or four years from the planting. The latter plan will be the more economical in the end. To gain both purposes we have planted double the number of Vines—one half to fruit, the others to be established, and then the first to be cut out.

VINERY 15 FEET LONG (A Young Amateur).—If you do not want to grow much below the Vines, then have five Vines—viz., one Royal Muscadine, one Buckland Sweetwater, two Black Hamburgh, and one Trentham Black.

PLUNGING POTTED VINES (Broule Place).—The Vines will be safe enough treated as you propose; but, of course, they will do little good if left in the border.

PLANTING AN EARLY AND A LATE VINERY (S. E. W.).—In the early vinery you might have all the border (17 feet in width), inside, and plant 2 feet from each side, or plant in the middle and train down. As you can have a border outside on the west side, you might, as you propose, give the most of the inside border to the Vines on the east side of the span roof, and, planting the Vines on the west side for that side, allow the roots to go out beyond the wall, protecting the outside border in winter. For the late house we would plant the Vines inside on both sides of the house, and allow the roots to go out into a border on the one side, and beneath the lawn on the other side. Little protection will be needed for these borders, except protecting them from wet in autumn and winter. For each house we would have eight Vines—four on the side. In the first house we would plant one Dutch Sweetwater, one Royal Muscadine, four Black Hamburghs, one White Frontignan, one Black Muscat of Alexandria. For the late house we would have two Muscat of Alexandria, two Newwood Muscat, two Lady Downe's, one West's St. Peter's, one Trebbiano. These will want heat, especially when coming into bloom, and they will keep well.

VINES IN POTS (Young Beginner).—Did we wish to obtain what fruit we could from these rather strong Vines in 8-inch pots, we would leave them in the pots, but set them inside of your 12 or 14-inch pots or boxes, make larger holes in the bottom of the smaller pots, fill up with good compost, and give rich mulchings. However, if you do as you propose—re-pot at once into 12-inch pots, we should merely loosen the roots a little outside the ball, and place the fresh compost firmly between the ball and the pot, on the clear understanding, however, that success will be greatly owing to the practice you propose—namely, plunging these re-potted plants in warm manure, whilst the tops are kept cool or exposed, so as to encourage fresh rooting before the buds swell. See "Doings of Last Week" in last number.

FORCING STRAWBERRIES (Idem).—In the new house, 60 feet by 18, in which you propose having a central bed and two side ones, we cannot say that in these beds you will be able to make Strawberries in pots pay, as we fear they would be too far from the glass for early work. After March and April they would do. The sorts we would recommend are Keens's Seedling, British Queen, Oscar, Sir Charles Napier, and Sir Harry. We have not much faith in the plan of clearing off the Strawberries in the middle of April, and filling with 150 Vines in pots, so far as making money from the plan is concerned. You may use pet Vines for a season or two before other Vines grow; but if you want the house to pay, you should plant Vines to continue at once. Vines in pots if fruited heavily will do little more good.

POTATOES FOR EXHIBITION (Murphy).—The earliest Potatoes for a show in the middle of June, whether from frames or from the open borders, are Hogg's Early Goldstream and the Early Handsworth (Round). The former is a first-rate variety for eating, and the latter, though handsome, is inferior for table use. Soden's Early Oxford is a variety that will give fine round tubers by the above date, but "few in a hill." Of early Kidneys, Sutton's Racehorse, *alias* Mitchell's Early Albion; Mona's Pride, *alias* the old Early Ashleaf (?); Almond's First Early, *alias* the old Walnut-leaved Kidney (?), and Webb's Telegraph, are four Kidneys which will prove the best for the early show table. The first three cannot be beaten for quality. For show varieties in the first week of September, Edgemoor Second Early and Almond's Yorkshire Hero—superior strains of the Lapstone family, as being very handsome and very first-rate for eating. It is doubtful if Wheeler's Milky White could be in perfection thus early in the open ground. It is first-rate. Of round kinds, Transell's Seedling and Danitree's Seedling Round.

EVERGREEN FOR ARCADE (A. G.).—*Crataegus pyracantha* will suit you, and so will the plant you name.

EVERGREENS FOR PYRAMIDS (An Old Subscriber).—*Thuja Lobbi*, *Cupressus Lawsoniana*, and *Thujopsis borealis* all form pyramids, and will bear cutting, but it spoils their natural elegance and gracefulness.

FORCING PEACH TREES IN POTS (Gregory).—Your plunging the pots in a bed of leaves will be proper, providing the heat is not violent, and the pots are gradually withdrawn from it, so that no check may be given. You must not keep them plunged until the roots strike through into the leaves and then withdraw the pots, as the check may cause the fruit to fall or be poor; but it will be beneficial if you can leave the pots in the leaves until the fruit is ripe, otherwise you had better not plug them. The only danger of plunging is a check being given to the trees by the loss of the heat and moisture, or the destruction of the roots that may

find their way through the holes in the pots. Trees planted in borders and trained to a trellis are preferable to those grown in pots, for they give less trouble in watering, but good Peaches may be obtained from trees in pots, and from the trees being in pots they are more convenient and suitable for places where it is not desirable to have a house wholly devoted to them. Many can find room for a few trees in pots, but cannot devote a house exclusively to them, and even in places where there are Peach houses with trees in borders, and it is not desired to force early, a few trees in pots are very useful. Good Peaches are grown, both with and without heat, on trees in pots, and we have no doubt of your succeeding.

PASSIFLORA QUADRANGULARIS (W. H. H.).—There is no need for setting the fruit. It does so rather freely naturally when the plant is not too vigorous, but is rather shy when the plant is grown in rich soil, and has abundance of room for the roots. Confine the roots more, give abundance of air, all the light possible in a position near the glass, and in the early part of the day apply pollen to the stigma with a camel-hair pencil.

Books (Titmouse).—The "Vine Manual" will suit you. You can have it free by post from our office if you enclose thirty-two postage stamps with your address. (A. C.).—No supplement to the "Cottage Gardeners' Dictionary" has been published.

Striking Epacris Cuttings (Titmouse).—The best time to propagate Epacris is from the beginning of March to the end of August, and the earlier the cuttings are struck the better it is for the well-being of the plants, as they can be potted-off and become established before winter. Take a 4 or 6-inch pot, half fill it with crocks, place over these a thin layer of moss or very fibrous peat, and then fill to within an inch of the rim of the pot with a compost of two-thirds silver sand and one-third sandy peat; then make level to the rim with silver sand. This done, take another pot a little deeper and wider, and put into it as many crocks as will raise the rim of the smaller pot to the level of the rim of the larger pot, and the space between their sides fill halfway up with small crocks, next put in a layer of moss, and then fill to the top with silver sand. A good watering having been given, the pots should be placed aside for the water to drain off, which it will be by the time the cuttings are prepared for insertion. In selecting cuttings preference should be given to those that have begun to grow, the young shoots being an inch or two long; take them off with a small portion or heel of old wood, some of the old wood being cut or taken off, and the heel smoothed with a sharp knife. If cuttings are taken from the young growth entirely, the shoots must be somewhat firm, more particularly the base. The cuttings should be put in around the sides of the small pot, and in circles towards the centre, not allowing them to touch each other. They should have a gentle watering and be allowed to dry; the pot should then be plunged in a mild hot-bed or where there is a temperature of 65°, a bell-glass being placed over the cutting pot, with the edge resting on the sand between the two pots. Shade from bright sun should be afforded, and the sand must be kept moist, for if the cuttings droop for want of water success is very questionable. The bell-glass should be taken off once a day and wiped dry. When the cuttings have struck root, the bell-glass should be gradually removed in order to harden them off before pottling.

PELAGONIUMS IN A COLD FRAME MILDEWED (Amateur).—Your only remedy is to keep the atmosphere drier by giving more air. It is hardly possible to keep the more tender kinds in a frame, on account of the frame having to be for a long time closed during severe weather. A little fire heat is necessary. Pick off the worst leaves, cut away any dead or mouldy stems, and dab the mildewed leaves and stems with flowers of sulphur.

PRIVET, BOX, AND RHODODENDRON PROPAGATION (J. H.).—Privet is best propagated from cuttings, which if put in in autumn in the same manner as cuttings of Currants, root well and become good plants in twelve months. Privet may be raised from seed, which should be sown when ripe, in beds of good, rich, light soil. Box, tree Box being the only suitable sort, is propagated by cuttings, which should be put in early in autumn or spring, in a warm sheltered situation in sandy soil. Seed may be sown in spring, and trees from seed grow the most rapidly and make the straightest best wood, which is very valuable. The Rhododendron is best propagated from seed, which may be sown in boxes or pans well drained and filled, or nearly so, with sandy peat and a layer of very fine sandy soil on the top. The surface should be made level and be watered, and the seeds scattered thinly and pressed in, covering them very slightly with silver sand. The pans may then be removed to a cold frame, where attention should be paid to shading from bright sun, and keeping the soil moist by watering through a very fine rose. A little moss may be placed over the pans; this will lessen the necessity for frequent waterings, but the moss must be removed when vegetation commences. The seedlings, when large enough to handle, ought to be pricked-off 3 inches apart, shading and keeping them close until they have again struck root; then gradually admit air until they are fully exposed. Keep the soil always moist, and protect the plants from frost and powerful sun.

WILD TAMARIND SEED SOWING (W. H. R.).—The Wild Tamarind requires the heat of a stove in this country, being a native of Sierra Leone. The seed may be sown now in sandy soil and placed in a stove, the pots being plunged in a hotbed of from 85° to 90°. When the plants appear give a moderate amount of air, and keep the soil continually moist. The nearer the plants are to the glass the less liable will they be to become drawn up. When large enough to handle they may be potted singly in small pots, and grown in the stove. A compost of one-third sandy peat and two-thirds loam, with a liberal admixture of sand, will suit them well. Afford plenty of light and air.

CUTTING IVY (Idem).—When Ivy reaches the top of the wall it is grown should be cut off. This will cause the shoots lower down to spread. If you wish to cover the top of the wall, then you will let the shoots grow over it. To cover a wall well with Ivy the first branches should be trained over the lower part, stopping them frequently so as to cause enough shoots to be produced for covering the wall. This effected, the covering of the upper part is a very easy matter, as the energies of the plant are chiefly directed to the top.

MUSHROOM-GROWING IN A PIT (G. P.).—The space, 30 feet by 3 feet, would answer admirably for growing Mushrooms. We would fill the space to within 1 foot of the top with any description of rather dry littery manure, and make the top foot of horse droppings with most of the straw shaken out. The droppings should be in a moderately dry state when used, and put on in layers, each layer being beaten quite firm before

another is put on. The bed cannot be made too firm. A gentle heat will be produced, and when this has declined to 90°, you may insert pieces of spawn 1½ or 2 inches square in the droppings, just placing the spawn so deeply as to cover it half an inch. The lumps of spawn may be put in 6 inches apart every way. Within a week the surface should be covered about an inch deep with good, rich, turfy loam, and it should be beaten and made quite firm. No water should be given for six weeks, and then the bed should have a gentle sprinkling, and be covered with a little hay. The soil after this should be kept moist, but avoid making it very wet. Protection from frost should be afforded.

PLUM TREES UNFRUITFUL (Idem).—The Plum trees which make vigorous shoots, but do not bear fruit, may be root-pruned, and the Pear trees as well. It will only be necessary to return into the trench the old soil, which is, no doubt, quite rich enough, if not too rich. In that case you may fill the trench with two-thirds loam from a pasture, taking the top 3 or 4 inches with the turf, which may be chopped, but not made very fine. The soil should be of a rather light sandy nature. To this add one-third old mortar from an old building, the older the better, well incorporated with the loam. The soil for the Pears should be a strong loam, but avoid the lime rubbish.

TRIF ASHES AS MANURE (Idem).—They are excellent for manuring all kinds of soils, and would do well for a flower garden, and in the kitchen garden especially for Onions and all the Brassica tribe.

CRINUM CAPENSE CULTURE (St. Denis).—This plant succeeds admirably, grown in pots. Do not put them into large pots now, but shift them into pots twice the diameter of the bulbs, providing good drainage, and using a compost of loam from rotted turves two-thirds, and one-third leaf mould or sandy peat, adding sharp sand liberally. Pot so that the neck of the bulb may be covered with soil. Deep pots are best. Water liberally when growth commences, and copiously when the plants are in full growth, gradually diminishing the supply when the growth is perfected, and in winter keep dry. After a good growth has been made expose fully to light and air, and keep dry, but not so as to affect the foliage. Probably your bulbs will flower, but that depends on the ripening of the growth the previous year.

LIANTHUS DAMPieri TRAINING (Idem).—It may be trained to upright stakes or to a wire trellis; but we consider upright stakes put in round the sides of the pot the best, the shoots being coiled round them. Training to a wall is bad, as walls are generally shaded; but the plant will do trained to anything, whether a trellis, globe, or wall, only do not train it in too thickly, nor keep it too close and shaded.

LILIUM ACRATUM versus LILIUM BROWNII (Idem).—The flowers of *Lilium auratum* are much larger than those of *L. Brownii*, and it is a better kind, but both are very desirable. The wood of Victor Verdier Rose is nearly thornless.

REPOTTING ROSES (A Correspondent).—The best time to repot Roses is early in autumn (September); but it may be done now. In potting, most of the old soil should be removed; but it is well not to injure the roots more than can be avoided. If the plants are required to be kept in small pots, then all the old soil may be shaken away, and any long straggling roots shortened. For soil, use two-thirds loam from a pasture, the top 2 or 3 inches, with the turf, and this slightly charred, chopped rather fine, and mixed with one-third dry old cow dung, will form a most excellent compost. Thoroughly decomposed hotbed manure or leaf mould may be substituted for the cow dung if the latter cannot be had. One-sixth of sharp sand may be added if the loam is not sandy enough. You may prune standard Roses on the Briar stock from this time up to the middle of March during mild weather, and you may cut weak shoots back to one eye, the strong to two or three, and the very strong to three or four buds, cutting-out the very weak and those shoots crossing each other.

HARDY RIDGE MELONS (Idem).—We have grown the American and several other varieties of these so-called hardy ridge Melons, and have had them of good size; but we found the flavour, though fair, not equal to that of Melons grown in frames or pits. They succeed best in a cold frame, with a slight bottom heat at the commencement. We fear you will not succeed with them without glass. Your mode of furnishing bottom heat to plants in pots is certainly novel; but we think the heat thus afforded will be too uncertain, and so liable to fluctuation as to do more harm than good. You may grow Melons in pots in a greenhouse by clearing out all the plants and converting the house into a stove, by shutting it up closely and economising sun heat, giving about one-fourth the ventilation you would were it used as a greenhouse. Your plan is certainly worth a trial. The Melons cannot have too light a situation.

FINE-FOLIAGED STOVE PLANTS (F. G.).—The following will succeed in the same house with Alocasias, Begonias, and Cladiums:—*Maranta Veitchii*, *Croton pictum*, *C. variegatum longifolium*, *Pandanus elegantissimus*, *P. javanicus variegatus*, *Spharogynis latifolia*, *Pavetta borbonica*, *Maranta roseo-lineata*, *M. regalis*, *Roya carnea variegata*, *Hibiscus Cooperi*, *Dracena stricta*, *D. draco*, *D. nigreresens*, *Dieffenbachia Barquiniana*, *Cyanophyllum magnificum*, *Cissus discolor*, *Anthurium Lindigii*, and *Ananassa sativa variegata*. *Alocasia macrorrhiza variegata* you should have kept dry, and if you do that it will assuredly become dormant. The leaves will come all right after a time; but a brisk heat must be given in spring, also a moist atmosphere and slight shade from bright sun.

HERBACEOUS CALCIOGLARIA CUTTINGS (C. W.).—They are not worth the trouble of propagating by cuttings, and never make good plants, at least not equal to those from seed. You may slip off any of the side shoots not showing for bloom, making the base smooth with a sharp knife, and trimming off the lower leaves for half the length of the cuttings, and then insert these in pans in a compost of loam two-thirds, and one-third leaf mould. The pan should be well drained and filled to within an inch of the rim with the compost named, and then to the rim with sand. Insert the cuttings round the sides, and at about 1½ inch apart, give a slight watering, and place them in a house where there is a gentle heat. The atmosphere should be kept moist and close, and shade from sun must be afforded. If the cuttings are taken in summer they may be inserted in a cold frame, and kept close and shaded from sun. When rooted they should be hardened-off, and potted-off singly in small pots.

STOPPING AZALEA SHOOTS (Idem).—You must not stop or remove the shoots that come beside the lower buds, as upon their preservation depend the plant's after-growth and future flowering.

MARRIOTT'S SELF-REGULATING BOILER.—"Rose" wishes to know if any

of the readers of the Journal have tried the above for the heating of hot-houses, and with what success.

POINSETTIA PULCHERRIMA CULTURE (S. B.).—It is a stove plant. It may now be cut down, and cuttings of the shoots form excellent small plants for flowering in autumn and winter. Cuttings with two joints are quite long enough. They should be inserted in sand in a hotbed, and have a brisk heat. The old plant, when it has made fresh shoots an inch or two long, should be repotted. Afford the plants a light and airy situation near the glass, so as to have them strong and dwarf.

VINE MANAGEMENT (A. Norrie).—The Vines with shoots from 4 to 6 feet long, which we presume is the length they are up the rafters, should be shortened to two-thirds their length; but if but recently planted you should cut them down, so that they may just reach the bottom of the rafters. When they begin growing rub off all but two of the uppermost shoots, and when these are a few inches long select the better and rub the other off. That left, you may train up the rafter about 15 inches, not 9 inches, from the glass, and let it grow to the top of the house without stopping, then take out its point above a joint. The laterals may be stopped on the second leaf half way up the rod from the bottom, and at the first leaf at the upper part of the rod. They may be all well to make shoots a foot long, and then be stopped, removing them by degrees in autumn. Do not have any side shoots at the upright part of the glass. You will not have any side permanent shoots until the second year, unless you have left the Vines to some extent up the rafter, then you will leave a shoot as near the bottom of the rafter as possible, another 9 inches higher up the cane on the opposite side, and so on, leaving the shoots 9 inches apart, but on opposite sides of the rafter, consequently the spurs will be 9 inches apart on the cane, and 18 inches from each other on each side.

CHARCOAL (Idem).—The sample of charcoal enclosed is the right kind for garden purposes, especially for plants in pots, and is what we recommend.

SHRUBS AND PLANTS FOR A SMALL TOWN GARDEN (Stephen).—For a smoky town garden the following will succeed; two of each will be quite sufficient for the space you name:—*Aucuba japonica maculata*, *Minors*, *Box*, *Berberis Darwinii*, *Gold* and *Silver-edged Hollies*, *Berberis aquifolium*, *Ruscus racemosus*, and *Skimmia japonica*. Of plants that require peat soil, plant *Rhododendrons* *Blandyanum superbum*, *Gen. John Waterer*, *Lefevreanum*, *Victoria*, *maculatum purpureum*, *cinereum*, and *Everestianum*, one of each; *Azalea hirsuta* and *A. sinensis*, *Erica vulgaris* *Hammuldi*, *aurea*, *Alporti*, *confolia alba*, and *clara*; *Kalmia glauca* and *K. latifolia*, *Vaccinium ovatum*, and *Ledum latifolium*. Of deciduous shrubs, plant *Bibes sanguineum*, white and yellow varieties, and *Lilacs*. Heptacodas do well; also Snowdrops, Primroses, Crocuses, Narcissus, Tulips, Hyacinths, herbaceous and tree Peonies, *Polemonium*

ceruleum, and its variegated variety, *Columbine*, *Papaver bracteatum*, *Phlox verna*, and the herbaceous varieties; *Pyrethrums*, *Pinks*, *Clove Carnations*, *Pulmonaria officinalis*, *Saxifraga umbrosa crenata*, *S. palmata*, *Scilla sibirica*, *Spiraea filipendula plena*, *Viola cornuta*, *Trollius europæus*, *Lythrum poscuium superbum*, *Lilium ausantiacum*, *L. candidum*, *L. martagon*, *Helleborus niger*, *Eranthis hyemalis*, *Draba aizoides*, and *Dielytra spectabilis*.

STRAWBERRIES—ROSES (A. Norrie).—If you refer to our last volume you will find the information you seek.

PAINTING CUTTING FRAMES (S. L. H.).—By painting the inside white more light is reflected upon the plants, and by painting the outside white less heat is absorbed, so that the woodwork is less liable to be warped.

GRAFTING A VINE (M. B. F.).—We have no knowledge of the effects consequent on grafting a Muscat of Alexandria on a Treutham Black, and the results from Vine-grafting have been so anomalous that we cannot venture to express an opinion. Can you not plant a Muscat by the side of the Treutham Black, and graft too? You would then be able to add to our knowledge, and yet lose no time.

THE GENUS CEREUS.—If your correspondent, Mr. Kent, will consult the "Natural History Review" for 1862, page 11, he will find the question of the specific difference of *Cereus sticticus*, *Libani*, and *decidua* fully treated by Mr. Hooker. To decide whether they are distinct species or not would be to solve the slightly knotty question of "What is a species?" Until this is done they appear to have as much right to be called distinct species as a vast number of other trees and plants.—A. O. W.

IMPERIAL BLUE PANSY.—What are the merits of this Pansy as a bedding plant? It was sent out last year by Messrs. Downie, Laird, & Luning; shortly afterwards I had a single plant of it, and the few flowers that escaped the propagating knife were really very fine, of a dark blue, yet not so dark as to be conjoined with purple. How does it succeed when sown in soil not specially prepared for it, and what are its blooming capabilities? Would the result of a cross between it and *Violæ cornuta* be likely to combine something of the profuse-flowering habit of that plant, with the broader breadth and substance of petal of the Pansy?—AYESHIRE GARDENER.

FRUIT TREES UNDER-POTTED (H. Ems).—Fruit trees thrust into pots which just hold them, leaving no space unfilled, and which trees cannot be repotted, may have a rim of zinc 2 or 3 inches deep inserted inside the pot, to hold some forcing sing. We fear that the draughts you kindly offer would not be decorative!

NAMES OF FRUITS (Rev. Mr. McCalmont).—Your Apple is Pearson's Plate. (W. Crocker).—The small Apple is Sam Young, the larger and greener we do not know. Probably it is a local variety, and the name by which you say it is largely may be the correct one.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending January 28th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE

SEPARATE PRIZES FOR LIGHT AND DARK BRAHMAS.

MESSRS. Worthington, Pares, and Crowley have appealed to secretaries of poultry shows, advocating justice to the Light Brahmas. There cannot be a doubt that a more definite arrangement in the prize list is necessary for the awarding of extra prizes between these two varieties of one class. To ignore the existence of the qualities of the Light over the Dark, or *vice versa*, is indeed one of the greatest errors that could be made in the arrangements of a poultry show, which to be useful and carry out the object intended, should place as far as possible all varieties and classes on an equal footing, more especially in a class that is advancing in the good opinion of poultry fanciers generally, and which is acknowledged to be one of the best descriptions of poultry extant. This is aptly illustrated by the great increase of fresh exhibitors at the principal shows. The correctness of Mr. Pares' remarks as to there being well-filled classes of the Lights is fully proved, as in many shows they exceed in number of entries the Dark. To remedy this evil it is necessary there should be no invidious distinctions; let the prize list be so arranged as to prevent any preponderance of one class of a variety over another.

I have always promoted an equality in the prize lists. If a cup is offered for one variety, either Light or Dark, well

enough; but if a silver cup is offered for the best pen in two or three distinct classes or varieties, then nine times out of ten it will open the doors to a serious, long chapter of complaints, whereas, if confined to one variety, it cannot be otherwise than satisfactory to every one. I am fully alive to the great difficulty committees have in offering silver cups for every variety, but I am confident it would be far preferable to omit cup prizes altogether than couple the varieties.

I hope these remarks may lead to some other secretaries advancing their opinions, for the purpose of obtaining an equality in prize lists generally.—PHILIP WARREN.

FOUR-TOED HOUDANS.

ALLOW me to enter my protest against those who would improve on Nature. Mr. Schröder would do so in robbing Houdans of their fifth claw. Why? That they may be less liable to foot disease. I believe I have kept them longer, and have more at the present time, than any one in England. I have no foot disease; I have never had any. I believe the fifth claw has no more to do with foot disease than the thunder has with hatching Swans' eggs. Let us keep the birds as they have come to us, and as they are described by the painstaking and intelligent M. Jacque in his book as they have been known in France "time immemorial." In these days of criticism and hard competition we should rather try to get up to the standard by breeding good birds than to lower it to admit those of doubtful purity. To do away with the acknowledged attributes

of a breed is to open the door to mongrels of every description, causing vexation to the real amateur, and often bringing a good breed into disrepute.—A SOMETIME DWELLER IN FRANCE.

I HOPE I may be allowed to enter a strong protest against four-toed Houdans. The pure Houdan breed is as clearly five-toed as the Dorking, and where the four toes come out it is due to attempts at crossing with Brahmas and Coelins in hopes of getting more size. This I think has been a great mistake, and the French poultry farmers themselves now find it so.

The Houdan is not naturally a large fowl; it is an excellent layer, and puts on a great deal of flesh on very small bones; and the attempts at crossing, by which four-toed Houdans are produced result in many cases in bad sitters, and in fowls with large bones and less flesh, though a certain apparent size may be gained.—SANGRE AZUL.

I was very glad to see Mr. Schröder's remarks in your last number relative to the fifth toe in Houdans. It is not yet too late to get rid of this ugly and troublesome deformity, and I believe most breeders would be well pleased to do so, if they were not deterred by the fear of disqualification at exhibitions.

In my experience of this valuable breed I have found that a large proportion of the chickens, especially the pullets, come with either four toes or with the fifth toe very imperfectly developed, though the birds possess all the other qualifications of the breed in just as great perfection as their five-toed sisters; and it is mortifying to be obliged to consign promising young birds to the cook merely because they are without a member which can be of no conceivable use to those that have it.

I believe the fifth toe in Houdans is derived from a Dorking cross in some previous generation, thrown in for the sake of improving the size. Many of the imported birds are without it; and I hope yet to see the day when the fifth toe will be considered, as I believe it is, a mark not of purity but of cross-breeding.—EBLANA.

ARE PIGEON ROUP AND CANKER INFECTIOUS? CROSSING WITH MEALY BIRDS.

I CANNOT but think, with all due deference to so great an authority, that Mr. Huie is mistaken when he says that "not one disease to which they (Pigeons) are liable, is even infectious," and that "roup, the most likely of all to be infectious, is not so."

I have been a breeder of Pouters for some years, and during that time the only two serious diseases that my birds have ever been troubled with have been canker in the mouth and roup, but as far as my experience goes, both of these complaints are most decidedly infectious, the former especially so, and I think most fanciers will bear me out in this.

Mr. Huie also strongly condemns a cross between a Yellow and a Mealy Pouter. I possess a few good Yellows, and one of the best birds of this colour that I bred last year was obtained by crossing a Yellow cock with a mealy-barred hen, not a semblance of a bar appearing in the young bird. I also obtained some good-coloured Blacks from a Black and a Mealy, the latter being bred from a Red and a Black.—W. R. ROSE, *Cranley Hall, near Kettering*.

[I am glad Mr. Rose gives me the opportunity of proving my assertions in regard to the diseases of Pigeons, which time would not admit of in my previous communication to the Journal.

During my experience in breeding domestic Pigeons (over thirty years), canker, or cancer, in the mouth has been rare with me. Some years ago I had a young Trumpeter, and just before its being able to leave the nest, I discovered, from the bird's hard breathing, that something was wrong; looking into the throat I found it almost closed by a large lump like a fungus, caused by this disease. The bird not being of much value, with the broad end of a pencil I pressed the lump downwards into the crop. Profuse bleeding followed for a few minutes, and the bird was well, as it flew about for years after without any return of the disease. Neither of the parents of this bird was ever affected. The year before last I had a pair of Mottled Trumpeters, a different strain from the former; the hen had a bad mouth from this disease, yet her mate was never affected by it. They reared four fine birds of their own, and being pressed at the time for feeders, I placed under them a pair of my young Pouters, destroying their own eggs just hatching. This hen and her mate reared the Pouters, and they became

fine, large, healthy birds, all unaffected by the disease. The Trumpeter hen is still alive, and now well.

Roup is a very troublesome disease, still I do not consider it infectious. At present I have a pair of Red Pouters, the cock ten years old and the hen three years, also a pair of Yellow Pouters about nine years old; both pairs were matched all last year, and, strange to say, both hens have been ill with roup since the moulting time in 1866. Sometimes for three or four weeks, or longer, at a time they were quite well, then the disease would return bad as ever, and I have sometimes found in the morning lumps of yellow mucus adhering to the partition boards close to where they had been sitting during the night. The mates of these two hens are, and have been all along, in perfect health and fine show. Both hens laid during the season, and notwithstanding all the "billing and cooing" that went on, their mates never were once affected in the slightest degree, nor even one other bird in my whole collection, from thirty to forty pairs living in the same house.

I hope that Mr. Rose and our other brethren in the "fancy" will consider that I have proved to a demonstration my former assertions; were it necessary I could furnish many other instances.

It is from observations and upon experiments such as these that I found my assertions; and if our friends would only come forward and candidly give us their experience, although in a few lines at a time, we should rapidly advance in our pastime, not on theories or nightmare remembrances, but on a pathway paved with facts "true as steel."

My remarks on breeding the various colours in Pouters were as a matter of course only general. What we want is *detail*, but that we cannot obtain, unless writers understand the subjects on which they write. In breeding for yellow we want a rich, solid, deep orange colour, not a light, or pale, or streaked colour, with or without light or slight touches showing where the bar should be if it were required. Five minutes' consideration will bring us to the conclusion that no bird showing a bar should be introduced, or any bird of such blood. A rich-coloured Red and a Yellow should be matched to breed from for Yellows, the Yellow being the younger bird. The mealy colour of itself is too light, leaving the bar out of the question. I have seen good Yellows bred in the manner Mr. Rose names, but they are seldom up to the mark; besides they are few and far between, and what is most provoking, the birds that are worst in colour, or showing a slight or defined bar, are as a general rule the most handsome.

When I talk of breeding Yellow Pouters, or Pouters of any colour, I point to a strain that will not fail to breed true, marking excepted, in colour. I am not surprised at the colour of the birds Mr. Rose has bred, and in corroboration of this I may mention that I produced a most elegant Blue-pied, and in the following nest a Chequer, from the largest and, I believe, most handsome pair of Black-pied Pouters that were ever seen; the male bird was known by Scotch fanciers as the "Black Prince." These facts show how colours have been mixed, but we have been working for size and shape; these being attained, we shall by-and-by arrive at the desired colour.

Mr. Rose omits telling us what reason he has for thinking the diseases in question infectious.—J. HUIE.]

RAILWAY CHARGES.

THE excessive railway charges that poultry exhibitors have to submit to are a great annoyance and injustice. The most curious circumstance is that I invariably am charged more—in fact, nearly double carriage for my birds on their return journey from any exhibition than I pay when I dispatch them thither. Can any one explain this? or will any one kindly say if he is troubled with the same grievance? For instance, the other day I sent some birds to a show, and pre-paid 2s. 9d.; on their return journey I paid for them 4s. 2d. Cannot we oblige the companies to charge equally for birds both to and fro?—PARTRIDGE COCHIN.

PHILOPETERON SOCIETY.

THIS Society held its twenty-first annual Show on Tuesday the 14th inst. at the Freemasons' Hall, Great Queen Street, Lincoln's Inn. It was a source of regret that on the day of its coming off, owing to a mistake on the part of the manager of the Freemasons' Tavern, the Society had to be content with such a poor substitute for their usual rendezvous—the Grand Hall; as many of the birds, although shown in the mahogany pens of the Society, were seen to a dis-

advantage, which we could not help regretting. We therefore simply give a list of the names of the exhibitors of the birds. Most of the exhibitors are generally foremost at our shows where prizes are competed for, and their names are a guarantee of the quality of their birds, though many members who do not exhibit for prizes showed birds of superior quality.

Pouters were shown by Mr. Volekman and Mr. Thackray; Carriers by Mr. Crossley, Mr. Else, Mr. Betty, Dr. Square, and Mr. Hedley; Almonds by Mr. Esquilant (the President), Mr. Thackray, Mr. Crossley, Mr. Merck, and Mr. Lucy; Short-faced Balds, Beards, and Kites by Messrs. Esquilant, Mr. Percivall, Mr. Merck, and Mr. Lucy; Jacobins by Mr. Morris, Mr. Carrell, Mr. Merck, and Mr. Betty; and Owls by Mr. Hedley and Mr. Crossley. Dragons came from Mr. Crossley, Mr. Percivall, and Mr. Betty; Long-distance birds from Mr. Hudson; Trampeters, Turbits, Pinnswicks, &c., from Mr. Thackray, Mr. Hedley, Mr. Else, and Mr. Percivall; and Parbs from Mr. Crossley and Mr. Hedley.

OLDHAM POULTRY AND PIGEON SHOW.

THIS Exhibition, which opened on the 24th inst., is the first that has been held in Oldham, so that an entry of upwards of four hundred pens must be deemed a great success. That even a far greater number of entries might have been obtained is beyond all doubt, as the Committee felt themselves compelled to decline the applications of very many intending exhibitors, on the simple ground that all available space was already engaged. The Co-operative Hall at Oldham is spacious and well ventilated; but when densely filled, as it was in this case, it is not nearly so well lighted as could be desired for the purposes of a poultry exhibition. In fact, no inconsiderable number of the birds were placed in positions so unfavourable that it was difficult to determine at first sight even their respective varieties. The feeding and attention paid to the specimens were most satisfactory, but from being a first show, some of the minor details would be considerably improved by a greater amount of promptitude and dispatch. However, when in future years the Committee, aided by the experience now afforded them, contemplate other meetings, no doubt these shortcomings will be rectified.

The *Spanish* and *Cochins* were very good classes, some of the White *Cochins* being particularly good. Many of the *Gamb* fowls were excellent, but from over-exhibition some were fast lapsing from good condition. The *Hamburghs* were also superior, but the great want of light prevented them being seen to advantage. The *Polands* were unusually perfect, and embraced a liberal entry. There was a very considerable collection of the new varieties of *French* fowls, and the classes of *Pigeons* throughout were particularly good, a great variety of the newest breeds proving generally attractive. In spite of an extremely high wind, combined with a bitterly cold state of the atmosphere, the attendance of visitors was remarkable, both as to numbers and respectability. Mr. James Dixon, of Bradford, being prevented by the sudden illness of a member of his family from officiating, the whole of the judging was completed by Mr. Edward Hewitt, of Sparkbrook, near Birmingham.

SPECIAL CLASS—First, P. Unsworth, Lowton (Silver *Polands*). Second, K. Dawson, Oldham (Golden-spangled). Third, Mrs. S. Lancashire, Tonge (Silver-spangled *Hamburghs*). Highly Commended, W. Hargreaves, Bacup (Dark *Brahmas*); M. E. Wrigley, Middleton (Gold-pencilled *Hamburghs*); J. Andrew, Ashton-under-Lyne (Golden-spangled *Hamburghs*); J. Clegg, jun., High Crompton, Oldham (Black *Hamburghs*). Commended, Mrs. A. Bamford, Tonge Lane, Cinnamon and Buff *Cochins*; S. H. Stott, Rochdale (Toulose *Geese*). (This was for the Mayor's Prizes.)

SPANISH (Black).—First, Hon. Miss Douglas Pennant, Penryn Castle, Bangor. Second, Mrs. Cliff, Hanley. Third, W. & F. Pickard, Thorne, near Leeds. Highly Commended, N. Cook, Chesham; H. Wilkinson, Earby; J. Thresh, Bradford. Commended, M. Saxon, Manchester.

DORKINGS (Any variety).—First, E. Charlesworth, Manchester. Second, J. White, Warlaby, Northallerton. Third, T. Tatham, Kingsthorpe. Highly Commended, W. H. King, Rochdale. Commended, J. Stott, Healey; Hon. Miss Douglas Pennant; J. White.

COCHINS (Any variety).—First, C. W. Brierley, Middleton. Second, T. Bott, Bury. Third, W. Bamford, Manchester. Highly Commended, T. Maxwell, Salford; Miss E. Hamner, Leighton Buzzard; J. T. Berry, Sheffield; Hon. Miss Douglas Pennant; C. W. Brierley. Commended, S. Harrop, Middleton.

COCHINS (Any other variety).—First and Third, C. W. Brierley. Second, T. Bott. Highly Commended, W. T. Ascroft, Oldham (Partridge *Cochins*); J. Cooper, Oldham (Partridge *Cochins*). Commended, J. Artinall, Tonge, Middleton (White *Cochins*).

BRAHMA POOTRA (Any variety).—First, W. H. King, Rochdale. Second, T. Pomfret, Preston. Third, B. Carlisle, Rishton, Blackburn. Highly Commended, Col. Stuart Wortley. Commended, W. Bamford.

GAME (Black Red).—First, H. M. Julian, Hull. Second, J. Mason, Worcester. Third, W. Biney, Manchester. Highly Commended, J. Jackson, Bury. Commended, C. Travis, Thurgoland, Sheffield.

GAME (Brown Red).—First and Second, C. W. Brierley. Third, E. Close, Kingstown, Dublin.

GAME (Any other variety).—First, C. Travis. Second, M. Julian. Third, C. W. Brierley. Highly Commended, T. Dyson, Halifax; J. Mason. Commended, B. Consterdine, Littleborough.

HAMBURGHS (Golden-pencilled).—First, J. Merrall. Second, H. Pickles, jun. Third, W. Farr, Patricroft. Highly Commended, Mrs. Farguharson, Stow-on-Wold.

HAMBURGHS (Silver-pencilled).—First, W. Wilson. Second, J. Preston. Allerton. Third, J. Smith, Coalham, Earby. Highly Commended, T. Sharples, Crawshaw Booth, Rawtenstall; J. Platt, Dean, Bolton; W. & J. Bairstow, Farncliffe, Bingley.

HAMBURGHS (Golden-spangled).—First, S. Burn, Whitby. Second, T. Ogden, Hollinwood. Third, R. Simpson, Chadderton. Highly Commended, K. Dawson; H. Pickles, jun.; F. Greenwood, Rochdale; R. Simpson, Chadderton. Commended, T. Ogden; F. Warbrick, Oldham; J. Preston; J. Andrew.

HAMBURGHS (Silver-spangled).—First, S. Lancashire, Middleton. Second, S. & R. Ashton, Mottram. Third, W. Parr, Patricroft. Highly Commended, J. Preston; J. Jackson, Bury. Commended, J. Lancashire, Tonge, Middleton.

HAMBURGHS (Black).—First, J. Hope, Chadderton. Second, Rev. W. Serjeantson, Acton Burnell Rectory. Third, Mason & Walker, Deaton, Manchester. Highly Commended, C. F. Copeman, Birmingham; R. Fitton, jun., Oldham; J. Lancashire; Mrs. M. Lancashire, Middleton. Commended, J. Hope; J. Jackson; W. Farr; Mason & Walker, Denton, Manchester.

POLANDS (Any variety).—First and Second, P. Unsworth. Third, W. and T. Pickard, Thorne, Leeds (White-crested Black). Highly Commended, R. Charlesworth, Manchester (Black with White Crests); W. & T. Pickard (Silver-spangled). Commended, E. & H. Comber, Warrington (Silver-pencilled); R. Charlesworth (Black with White Crests).

BANTAMS (Black or Brown Reds).—First, R. Charlesworth. Second, J. Allen, Oldham. Third, W. Biney, Manchester. Highly Commended, S. Harrop, Middleton; J. Butterworth, Blackley, Manchester; J. Davies, Oldham; C. Outram, Sheffield; C. W. Brierley. Commended, J. R. Robinson, Sunderland; J. B. Riley, Orvendale.

BANTAMS (Any variety).—First, Tonkin & Tuckey, Bristol (Black). Second, (Mason & Walker, Black). Third, S. & R. Ashton (Black).

ANY OTHER VARIETY NOT NAMED ABOVE.—First, Miss E. Hamner, Leighton Buzzard (Creve-Coeur). Second, Col. Stuart Wortley (La Fleche). Third, N. Cook, Chesham (Houdans). Highly Commended, S. H. Wood, Diggle, Saddleworth (Andalusians); T. Robertshaw, jun., Ilkington (Andalusians); R. Charlesworth (Malays).

DUCKS (Aylesbury).—First and Third, E. Leech, Rochdale. Second, M. Farrand, Dalton, Huddersfield.

DUCKS (Rouen).—First, J. J. Stott. Second, T. Bott. Third, E. Leech. Commended, T. Wakefield, Golburn, Newton-le-Willows.

DUCKS (Any other variety).—First, C. W. Brierley (Shell Ducks). Second, S. & R. Ashton (Carolinas). Third, T. C. & E. Newbitts, Epworth (Enochs Ayrean). Highly Commended, S. Burn, Whitby (Black East Indian); C. W. Brierley (Carolinas). Commended, J. Robinson (Wild Duck and Drake); T. C. Harrison, Hull (Carolinas); R. Charlesworth (Black East Indian).

GESE (Any variety).—First, S. H. Stott. Second, E. Leech. Third, and Highly Commended, E. Brooks, Oldham (Spanish). Commended, J. Wrigley.

SELLING CLASS.—First, S. & R. Ashton (Golden-spangled *Hamburghs*). Second, P. W. Story, Daventry (White feather-legged). Third, W. & F. Pickard (Silver-spangled *Polands*). Highly Commended, K. Dawson, Cowlishaw, Oldham (Gold-spangled *Hamburghs*); N. Cook, Yew Tree House, Chesham (White *Cochins*); J. Holt, Middleton (Black *Hamburghs*). Commended, Mrs. Bamford, Manchester (Buff *Cochins*); J. Horrocks (Partridge *Cochins*); T. Gratton, Rochdale (Golden-spangled *Hamburghs*); J. Buckley, Werneth (Golden-pencilled *Hamburghs*); J. Andrew (Golden-spangled *Hamburghs*); K. Dawson (Black Spanish); H. W. Illingworth, Tile, Leeds (Buff *Cochins*); H. Wilkinson, Earby (Black Spanish); C. W. Brierley (Rouens).

PIGEONS.

CARRIERS (Any colour).—First, J. Waterhouse, Oldham. Second, H. Yardley, Market Hall, Birmingham. Commended, H. E. Whittaker, Middleton.

TROUBLES (Any variety).—First, J. Fielding, jun., Rochdale. Second, R. Whittaker, Delph Mill, Bolton. Highly Commended, R. Whittaker; T. C. & E. Newbitts (Almonds); H. Yardley. Commended, T. Newell Ashton-under-Lyne.

FANTAILS (Any colour).—First and Second, H. Yardley. Highly Commended, R. B. Chowler, Bolton Park, Skipton; J. Waterhouse; T. C. and E. Newbitts.

OWLS (Any colour).—First, J. Fielding, jun. Second, T. Newell. Highly Commended, H. Whittle, Newton Heath; J. Waterhouse; J. Walsh, City Wheatley, Halifax; J. Fielding; F. Sale, Derby; H. Yardley.

BARBS (Any colour).—First, T. Newell. Second, H. Yardley. Highly Commended, J. Fielding, jun.

DRAGONS (Any colour).—First, S. Shore, Newton Heath. Second, F. Sale, Rose Hill, Derby. Highly Commended, J. Waterhouse; D. Bromley, Over Hulton, Bolton; H. Yardley. Commended, S. Dronsfield, Oldham; J. Hill, Drayliden.

ANY OTHER DISTINCT VARIETY.—First and Extra Third, H. Yardley (Ice Pigeons, Black Fairies, and Blue Swallows). Second, T. Newell (Fairies). Highly Commended, T. Taylor, Oldham (Antwerps); H. E. Whittaker (Black and White Trumpeters); F. Sale (Yellow Jacks); H. Yardley (Archangels, Monks, and Swallows). Commended, J. Fielding (Red Turbits).

JEDBURGH POULTRY SHOW.

For the last ten years this Show has held a high position among the poultry exhibitions of North Britain, and it is a matter of congratulation to find that this year's meeting, which took place on the 21st, 22nd, and 23rd inst., has been more signally successful than any of the preceding ones. The entries numbered about sixty pens more than last year, and birds from the first poultry yards in the kingdom added much to the interest of the meeting. The Committee are most zealous and united in their exertions to promote the welfare of their Show, and the great additional support this year received in the way of subscriptions shows that the public appreciate the value of the undertaking.

It was a somewhat unexpected feature to find the *Spanish* so well shown in a district so far north as Jedburgh, for certainly, even as a whole, they would hold favourable comparison with the majority of shows, even in the south of England; and the *Dorkings*, for the most part, were scarcely less creditable, the "Silver Greys" being evidently the most popular variety of this useful breed in this particular district.

of *Cochin-China* fowls, and *Brahmas*, there was a most excellent display. *Hamburghs* mustered very strongly, and were mostly exhibited in first-rate condition. The *Pouter*s were the only variety that scarcely held so high a position as they have formerly at this Show. The unfavourable weather of late, it must be remembered, is especially unfavourable to these smaller breeds. *Geese*, *Ducks*, and *Turkeys* were shown by the most noted of our breeders, and a better display could not be wished for. *Carolinians*, *Mandarins*, *Shell-Ducks*, and other scarce breeds made the Variety class for Ducks especially interesting.

It was at Jedburgh, some few years back, that "selling" classes proved themselves so popular, and judging from the great number of birds entered and the large amount of sales effected, they still stand well in the good opinion of amateurs generally.

The collection of *Pigeons* was far in advance of those of preceding years, the competition in most of the classes being unusually close; and although it may appear invidious when all are so good to select any varieties especially, we cannot avoid mentioning the *Pouters*, *Owls*, *Jacobins*, and the Variety class, as being throughout of most extraordinary merit.

Fine bright weather gave additional zest to the Show; and the company embraced most of the nobility and gentry of the neighbourhood, together with an attendance on the last day hitherto quite unexampled.

SPANISH.—First, J. Taylor, Morpeth. Second, J. M'Innis, Broomlands. Third, J. Nelson, Eaglescliffe. Commended, Capt. Scott. *Chickens*.—First, Miss B. Ridpath, Edinburgh. Second, J. M'Innis. Third, J. H. Wilson, St. Bees. Highly Commended, W. Paterson; J. M'Innis. Commended, W. Paterson; D. Gellatly, Melrose.

DORRINGS (Coloured or Silver).—First, T. L. Jackson, Eush Ewes. Second, Lord Binning, Mellerstain. Third, Lady Baird, Newbith (Silver). *Chickens*.—First, W. Snowie, Philiphaugh. Second, Lord Binning (Coloured). Third, J. H. Wilson. Highly Commended, Miss Milne, Otterburn; T. Raines, Stirling. Commended, T. L. Jackson (Dark); D. Gellatly. *Pullets*.—First, A. Curle, Melrose (Silver). Second, T. L. Jackson. Third, M. Brooksbank, Manchester (Coloured). Highly Commended, Miss Milne (Silver); Lord Binning (Silver).

COCHIN-CHINA (Any variety).—First, J. Shorthose, Newcastle-on-Tyne. Second, E. A. Aglionby, Eastwaite Lodge, Hawkshead (Partridge). Third, E. A. Aglionby (Buff). Commended, W. Morris, Aberdeen; Bowman and Fearon, Whitehaven; Gunson & Jefferson (Both). *Chickens*.—First, Gunson & Jefferson, Whitehaven (Buff). Second, J. Nelson (White). Third, J. H. Wilson. Commended, W. R. Park, Abbotsmeadow, Melrose.

BRAHMA POUTRA.—First, J. Shorthose. Second, J. A. Dempster, Stirling. Third, T. Raines. Commended, J. Craw, Jedburgh; J. Poole, Ulverston. *Chickens*.—First, Mrs. Waugh, Lochmaben. Second, K. Jopp, Aberdeen (Dark). Third, D. Murray, Back Row, Selkirk. Highly Commended, E. A. Aglionby. Commended, K. Jopp (Dark); W. R. Park (Dark); M. Brooksbank; J. Craw.

GAME (Any variety).—First, G. Spalding, Kington. Second, H. M. Julian, Hull. Third, J. Brough, Carlisle. Highly Commended, J. H. Wilson. *Chickens*.—First, W. Urquhart, Langholm (Black Red). Second, H. M. Julian. Third, W. Tait, Heatherlie, Selkirk (Brown Red).

HAWKSBROS (Silver or Golden-spangled).—First, A. Heattie, Selkirk (Golden). Second, W. R. Park (Silver). Third, Bowman & Fearon (Silver). Highly Commended, W. France, Crief (Silver). Commended, J. F. Lovelace, Newark-on-Trent (Golden).

HAMBURG (Silver or Golden-pencilled).—First and Second, W. R. Park (Gold and Silver). Third, R. Barrow, Longtown (Golden). Highly Commended, Bowman & Fearon (Golden). Commended, W. & J. Baird, Fearncliffe, Bingley (Silver).

GAME BANTAMS (Any variety).—First, J. R. Robinson, Sunderland (Black Red). Second, W. Mabon (Dackwings). Third, T. Raines (Black Red). Highly Commended, Miss E. Oswald, Auchincruive (Black Red); Akroyd and Scott, Sunderland (Black Red); R. Macgregor, Perth (Black Red). Commended, W. Mabon, Jedburgh (Brown Red); W. Euston, Jedburgh (Brown Red).

BANTAMS (Any other variety).—First, T. Watson, Laners House, Crief (Golden Sebright). Second, J. R. Jessop (White Booded). Third, F. L. Roy, jun., Northorne, Kelso (Silver Sebright). Highly Commended, T. C. Harrison, Hull (Gold Laced); S. & R. Ashton, Mottram (White); J. R. Robinson (Black).

GEES (Any variety).—First, Mrs. Rirkett, Ainstable, Penrith (Toulouse). Second, R. Reed, Longtown (Grey). Third, Lord Binning (Toulouse). Commended, R. Shortreed, Kelso.

DUCKS (White Aylesbury).—First, W. Hood, Jedburgh. Second, D. Hardie, Sorbie Ewes. Third, Bowman & Fearon. Highly Commended, Little & Davidson, Canobie; A. Hogart, Leslie, Fifehire.

DUCKS (Rouen).—First, D. Hardie. Second, R. Shortreed, Atterburn. Third, Capt. Scott. Highly Commended, J. Gray, J. U. Sommer, Jedburgh.

DUCKS (Any other Distinct Breed not before mentioned).—First, T. C. Harrison, Beverley Road, Hull (Mandarins). Second, J. Jennison (Shield Drakes). Third, J. Jennison (Carolinians). Highly Commended, T. C. Harrison (Carolinians); J. Craw (Black American); J. Jennison.

TURKEYS.—First, J. Smith, Goutham. Second, T. L. Jackson. Third, H. Merkin, Driffield. Highly Commended, Lord Binning.

ANY OTHER DISTINCT BREED NOT BEFORE MENTIONED.—First, W. R. Park (Crève-Cœur). Second, J. Sword, Jedburgh (Gouldres). Third, J. A. S. E. Fair, Overwells, Jedburgh (White Dorkings).

SINGLE COCKS.—*Dorking*.—First, J. Y. Crig, Kirkcaldy. Second, Miss Milne. Third, T. Raines. Commended, D. Hardie. *Game*.—First, A. Thomson, Carlisle. Second, H. M. Julian. Third, J. Brough, Carlisle. Commended, T. Watson, Crief (Brown Red). *Hamb*.—First, Bowman & Fearon. Second, J. U. Sommer (Silver-spangled). Third, W. Bowe, Carlisle (Silver-spangled).

SWEETSTAKES FOR BANTAM COCKS.—First, J. L. Brown, Selkirk (Black Red). Second, J. Scott, Jedburgh (Black Red). Third, J. Dailie, Belle Vue, Aberdeen (Black Red). Highly Commended, J. Park, Jedburgh (Black Red); G. Yule, Melhewles (Brown Red); A. Wight, Jedburgh (Black Red). Commended, H. Scott, Jedburgh (Grey); R. Macgregor (Black Red); W. Paterson, Jedburgh (Brown Red); G. Pringle, Jedburgh (Black Red); J. Horley (Black Red).

SWEETING CLASS.—First, Gunson & Jefferson (A Flock). Second, J. A. S. E. Fair (Aylesbury Ducks). Third, T. L. Jackson, Driffield. Highly

Commended, W. R. Park (White Cochin); R. Benson, Darlington (Cochin-China Partridge); G. Bell, Wigton, Cumberland (Black Red Game); J. Musgrove (Silver-pencilled); W. Sinton, jun., Monklaw, Jedburgh (Turkeys). Commended, W. Bowe (Golden-pencilled Hamburgs); W. Lawrenson, Eaglescliffe (Silver-pencilled); R. Burrow (Golden-pencilled).

COTTAGEERS' PRIZES.—First, W. Sword (Gouldres). Second, H. Purves, Hawick (Dackwing Game). Third, J. Scott (Black Red Game). Highly Commended, W. Scott (Red Pile Bantams); W. Laidlaw, Sharp-law, Jedburgh (Silver-spangled Hamburgs). Commended, T. Brown, Jedburgh (Silver-spangled Hamburgs); R. Petherford, Jedburgh (Silver-spangled Hamburgs); G. MacMillan, Jedburgh (Duckwings Game Bantams); J. Hervey, Jedburgh (Black Red Bantams); W. M'Indie, Jedburgh (Spanish). Highly Commended, W. Scott (Pile Bantams); W. Laidlaw, Sharp-law, Jedburgh (Silver-spangled Hamburgs).

PIGEONS.

TUMBLERS (Short-faced).—First, R. Whittaker. Second, C. Cowburn, Cals, Leeds. Third, J. Hawley. Highly Commended, J. Hawley; F. Key, Beverley. Commended, T. Rule, Durham; C. Cowburn; J. Fielding, jun.

TUMBLERS (Any other than Short-faced).—First, J. Pringle. Second, J. Hawley. Third, G. Fawdon, Gateshead. Highly Commended, J. Hawley; H. Yardley; J. Fielding, jun.

FANTAILS.—First, W. R. Park. Second, J. Thompson, Bingley. Third, H. Yardley. Highly Commended, W. Martin, Ayton; W. R. Park; A. Crosbie, Melrose; J. Sharp, Johnstone. Commended, J. E. Spence, Musselburgh.

POUTERS.—First and Third, J. Grant, Corstorphine. Second, F. Key. Highly Commended, W. Martin; C. Cowburn; J. Grant. Commended, J. Hawley; H. Yardley; C. Cowburn.

NUSS.—First, B. Davidson, Swinton, Jedburgh. Second, W. R. Park. Third, W. Veitch, Jedburgh. Highly Commended, F. Key.

OWLS.—First and Second, J. Fielding, jun. Third, J. Thompson. Highly Commended, R. Patterson; T. Spence, Musselburgh; W. R. Park; J. Grant. Commended, W. R. Park.

TURBITS.—First, R. Patterson. Second, J. Fielding, jun. Third, W. R. Park. Highly Commended, J. Thompson; G. Fawdon; J. Scott; B. Patterson. Commended, J. Thompson; J. Campbell, Langholm; F. Key; G. Yule.

JACOBS.—First, J. Thompson. Second, G. Yule. Third, J. Spence. Highly Commended, J. Campbell; C. Cowburn; J. Sharp; P. A. Renwick, Kelso. Commended, J. Hawley; P. A. Renwick.

ANY OTHER VARIETY.—First, W. Martin (White Dragon). Second, J. Hawley (Starlings). Third, H. Yardley (Ice Pigeons). Extra Third, J. Thompson (Isabels). Very Highly Commended, C. Cowburn (Archangels); J. Campbell (Black Magpies). Highly Commended, J. Fielding, jun. (Carriers); J. Bell, Newcastle-on-Tyne (Carriers); W. Robertson, Glasgow (Black Carriers); P. A. Renwick (Black Barbs); J. Grant (Rough-legged Tumblers). Commended, H. Yardley (Toys); J. Sharp (Ice Pigeons).

SELLING CLASS.—First, R. Davidson (Victorias). Second, J. Thompson. Third, J. Hawley. Highly Commended, R. Patterson (Turbits); J. Hawley; A. Goodfellow, jun. (Blue Pouters); J. Thompson; F. Key; P. A. Renwick (Turbits). Commended, A. Goodfellow, jun. (Black Carriers); J. Thompson; W. R. Park (Owls).

CANARIES.

SCOTCH FANCY (Yellow).—*Cock*.—First, R. Bell. Second, J. Kemp. Highly Commended, R. Bell. Commended, W. Hardie. *Hen*.—First, J. Hope, Galashiels. Second, J. Blaikie.

SCOTCH FANCY (Buff).—*Cock*.—First, J. R. Thompson. Second, G. Park. Commended, R. Scott, Jedburgh. *Hen*.—First, R. Bell. Second, J. Kemp. Commended, W. Tinline, Galashiels.

BELGIAN FANCY (Yellow).—*Cock*.—First, G. Park. Second, B. Gilchrist, Berwick-on-Tweed. Highly Commended, D. White, Leith. *Hen*.—First, J. Kemp. Second, W. Tinline.

BELGIAN FANCY (Buff).—*Cock*.—First, H. Donald, Galashiels. Second, J. Kemp. Commended, W. Tinline. *Hen*.—First, D. White. Second, B. Gilchrist. Commended, W. Tinline.

FLOCKED (Yellow).—*Cock*.—First, J. Hope. Second, W. Forrest, Galashiels. Highly Commended, J. Cleghorn, Galashiels; A. Ferguson, Kelso. *Hen*.—First, J. Dalgleish, Galashiels. Second, W. Tinline. Commended, G. Walker, Kelso; J. Cleghorn.

FLOCKED (Buff).—*Cock*.—First, J. Keith. Second, J. Dickson, Leith. Highly Commended, T. Darling, Hawick; G. Hollands, Jedburgh. Commended, S. H. Jeffrey, Jedburgh. *Hen*.—First, J. Hope. Second, G. Hollands. Commended, W. Tinline; J. Wallace, Jedburgh.

JUDGES.—For *Poultry* and *Pigeons*: L. Hewitt, Esq., Eden Cottage, Sparkbrook, Birmingham. For *Canaries*: J. Robertson, Esq., Barnstisland.

UTILISING AND UNITING CONDEMNED BEES.

(Continued from page 88.)

HAVING unpacked my empty hives, and all things being ready, I proceed either by close or open driving as may be best suited to my purpose. The first being the most rapid and certainly the least formidable to a beginner, whilst it answers every purpose when it is not desired to capture the queen, I will begin by describing it. Commence by standing the bucket firmly on the ground about a yard from the stock to be operated upon. Unroll the cloth and cord, taking care of the pin, and lay them, with two empty hives and a bee cloth, on the ground beside the bucket. Next light the fumigator, and blow a little smoke into the hive's mouth. As soon as the bees retire the hive must be slightly raised from its floor board, and a few whiffs of smoke blown under it all round. Then boldly lift the hive altogether from its place and steadily invert it on the bucket, covering it immediately with one of the empty hives, and closing the junction of the two by first wining the cloth round them, and temporarily fastening it by means of the pin,

and then firmly securing it by four turns of the small cord, taking two turns round the upper and two round the lower hive, and tying the two ends together. The bees within being thus safely enclosed, the floor board should be swept clear of stragglers, and immediately covered with the bee cloth, upon which the second empty hive may be placed to amuse those returning from the fields, and the united hives with the bucket conveyed to a shady spot at a little distance. Here it will be found very convenient to stand the hives and bucket upon one of the borrowed chairs, whilst the operator seats himself upon the other, and then a smart and regular rapping of the full hive with the palms of the hands should take place. In about ten minutes the great majority of the bees will generally be so alarmed as to quit their own domicile and take refuge in the empty one—a fact which may be ascertained by listening to the noise made by them in ascending. At the expiration of from ten to fifteen minutes the cloth may be removed, and the hives sufficiently separated by raising one side of the upper one to admit of inspecting the interior. Few bees will be disposed to escape, and very rarely will they commence an attack.

If nearly all have ascended into the hitherto empty hive, it may at once take the place of the decoy hive on the floor board, and the few remaining bees having been brushed out with a feather, the full hive may be conveyed in-doors. If, on the other hand, many bees still adhere to their original domicile, or if, as is sometimes the case, only a few stragglers are found to have quitted it, the one side of the upper hive should be upraised a few inches, and, being prevented from slipping by the iron skewer being stuck into the edge of the lower hive on the opposite side, kept steadily in that position with the left hand, so as to permit an unobstructed view of the interior, whilst the under hive is rapped smartly with the right. Believing, as I do, that the jarring of the combs is the principal cause which impels the bees to ascend, I disregard the dictum of authority, and always rap on one side of the hive which is opposite to the sides of the combs, endeavouring so to regulate the force of my blows, that whilst the vibration of the combs is so great that a bee can scarcely keep its footing on them, the concussion shall not be sufficient to detach them from their foundations. Such energetic measures admit of little delay on the part of the poor bees; a cry somewhat analogous to that of "*Sauve qui peut!*" speedily arises among them, as with vibrating wings and uplifted tails they "skedaddle" into the cheerless and ungenial shelter of an empty hive. During this rush upwards it is well to moderate the violent rapping into gentle tapping, just sufficient to keep the bees moving. If, as will probably be the case, the first exodus should not be sufficiently general, recourse must again be had to vehement rapping, and in this way a succession of panics may be produced until scarcely a bee remains in the hive.—A DEVONSHIRE BEE-KEEPER.

CHANGING FLOOR-BOARDS—CORK FOR HIVES.

In changing the floor-board is it necessary to loosen the hive from its board with a knife, or is the hive forced upwards with a screwdriver?

Is there any advantage or disadvantage in using a sheet of cork for the sides of a frame hive instead of the usual pressed straw? Of course all the edges of such a hive must be made of wood as usual. If there is no disadvantage, what thickness should the cork be?—C. A. J.

[An exchange of floor-boards should be effected with as little disturbance as possible. It would, therefore, be better to loosen the hive from its board with a knife the day before making the exchange.]

We are not aware that cork has ever been made use of as a material for frame hives, although we think it would be a good one, and should, therefore, like to see it tried. The usual thickness of a sheet of cork would probably do very well.]

OUR LETTER BOX.

OXFHAM SHOW (*An Exhibitor*).—Too many circumstances are unknown to us to justify our giving an opinion.

NEWARK POULTRY SHOW.—We are informed that by an error in the catalogue, the Rev. J. Chapman was stated to have taken the second prize in the Selling Class, whereas it was given to the White Cochins of Mr. F. D. Johnson, of Birmingham.

MARELE NEST EGGS (*A. E. F. C.*).—They are white or of a light cream colour and answer perfectly. They are to be bought of statuenries. There are composition eggs almost as hard to be bought at Mr. Baily's,

113, Mount Street, Grosvenor Square. We believe eggs of this sort are the only real cure for egg-eating. We have watched hens pecking at them pertinaciously, but they, of course, gave up the task in despair.

WEIGHT AND COLOUR OF DORKINGS (*C. X. H.*).—Nine pounds are a capital weight for a Dorking cock in stock condition. Two hens that weigh 15 lbs. are excellent birds. There is no standard of colour for Dorking hens. The white in the cock's tail is not of the slightest importance. The weights we have quoted above are not the heaviest that are ever met with, but they are good enough for success, and are hard to beat in running condition. Any practical breeder, or any one conversant with Dorkings as a breed in counties where no others are kept, will tell you the talk about colour as an index to purity is nonsense.

HENS PECKING THE COCK'S COMB (*C. C.*).—You will do well to remove the cock for a few days till the comb is healed. The sight of blood and raw meat is so tempting to the hens, that they will continue to peck at it till they have eaten through it. When it is quite dry you may put him back again, but in the meantime let the hens have plenty of green food, lettuce if possible. If, as we suppose, your fowls are not at full liberty (as we seldom meet with these cases save where the birds are in confinement, though not necessarily in a small space), let them have, if they have it not, grass in a growing state cut with heavy sods of earth; they will eat it all. Feed them also very sparingly. Cases like these often arise from over-feeding, and from a fat and craving condition of stomach. We have never known this treatment to fail in effecting a cure. You can rub the cock's comb either with citron or compound sulphur ointment. While we are on the subject we cannot help noticing that the cocks seem to like the process of having their combs and faces eaten. We have seen a Spanish cock stand still while the whole of the white sac that forms "the face" has been eaten, and when the hens had to jump to reach it, he has complacently lowered his head, to suit their convenience.

AYLESBURY DRAKE WITH WILD DUCK (*Old Duck*).—The cross you mention produces a very good Duck when you have it on the table, but it is open to one objection. The Aylesbury, if she sit at all, is a very hard sitter. It is generally considered a mistake to breed between sitters and non-sitters. You need not doubt the fertility of the union. We speak from experience when we say it is a certainty.

BOILED PARSNIPS AND CARROTS FOR POULTRY (*Rosa*).—Fowls will eat both carrots and parsnips boiled without injury, but they are not profitable food. If given at all, they should be given raw and chopped fine. Boiled potato is better food, but that is unprofitable if given unmixed with meal. Where fowls are kept largely on vegetables, as in Ireland, we invariably find they become very fat, but make no flesh, and always have diseased livers. You will do better and keep your fowls more economically on really good food, than on these poor substitutes. It is impossible to make badly-fed poultry pay its expenses, but where it is generously, not extravagantly fed and kept, we believe you may eat eggs and chickens for little or nothing, being paid for by those that go to market, or are otherwise sold. Ground oats, barley meal, occasional boiled potatoes, kitchen and table scraps and sweepings, with sometimes Indian corn, are the best food.

PLUMAGE OF DARK BRAHMAS AND GAME BANTAMS (*X. T.*).—You do not say in what part of the plumage the white feather shows. We cannot understand that it would be objectionable in any part of a Dark Brahma. It would be fatal to success in Black-breasted Red Game. The eggs may be set after three days, having previously ascertained that the cock is attentive to the hens. At this time of the year, especially, they sometimes have strange fancies and dislikes.

RED TINGE ON THE FACE OF A SPANISH PULLET (*W. and W. C.*).—It is never safe to discard a Spanish pullet eight months old because she has red over the eye. We have known such to become quite white after a few months more; but if it is the dark deep red that looks as though it laid on a black under ground, we have little hope.

A SPANISH COCK'S COME (*Idem*).—It should be of medium size, beginning near to the nostril, and going well over to the back of the head, not only upright, but stout enough to warrant the belief it will remain so. The spirals should not be long, and the entire surface should be smooth; there should be no indentation or thumb marks in front.

NEITHER MONEY NOR COCKRELL (*W. F. C.*).—We should write to the police, and then either deal with Mr. White before a magistrate or in the County Court, according to the information we received. We have your second letter. On no account send more money, but instruct your solicitor to sue at once. The *RECEIPT* ought to be returned, deducting 3d. for the office charge.

INFLUENCE OF MALE FIRD (*H. E. Limerick*).—We are of opinion that the influence continues until the hen is broody—that is, has laid her whole clutch of eggs. Some persons think three weeks having elapsed after intercourse has ceased is a sufficient time.

ALMOND TREMBLES (*L. F. Ferrié*).—The book is not sold by the booksellers.

LARK WITH CANARIES (*S. G.*).—A lark would do no harm in an aviary, but we would not advise keeping one along with the Canaries, more especially if they are expected to build. The materials for building may be given to Canaries about the 20th, or end of the next month.

SEX OF CANARIES (*W. A. J.*).—The bird being hatched so late in the year, will not be old enough to breed from until about next May. As to sex, it is difficult to decide when the bird is so young. Place the bird in a separate cage, and you will soon see whether it attempts to sing, if the male you speak of be in song.

PAYNE'S COTTAGE HIVE (*An Ardent Lover of Bees*).—If you purchased one, and there is a straw-hive maker near you, he must be very dull if he could not copy it, and thus supply your cottagers cheaply. We do not know the wholesale price.

BEES DECREASING IN NUMBER (*A Working Cabinet Maker*).—The probability is that the weak colony is dwindling away, owing to the death of its queen, and in this case it will be better to unite it to the next stock. It is only under very exceptional circumstances that it becomes necessary to confine bees whilst snow lies on the ground.

ISLE OF PERU.—If "T. C. H." will refer to map 30 in A. Keith Johnston's "Handy Royal Atlas," in the position I before indicated—among the islands in the North Pacific Ocean—he will find the small island of Peru.—W. H. K.

From observations taken near London during the last forty-one years, the average day temperature of the week is 45.2°; and its night temperature 31.1°. The greatest heat was 65°, on the 10th, 1831; and the lowest cold 3° below zero, on the 11th, 1845. The greatest fall of rain was 0.67 inch.

CORDONS.

READERS of this Journal will not regret seeing the subject of cordon-training so ably taken up by the Editors. I have frequently in these pages and elsewhere recorded my own convictions as to the very great advantages of a system that with obvious modifications is so well adapted for our climate, and which for orchard houses will soon alone prevail.

I regret that Mr. Robinson will not be induced to accept my definition of cordon-training as given eight years ago in my work so entitled; but as the view is supported by excellent authority, and especially by that of the Editors of this Journal, what is here stated is merely supplementary. Mr. Robinson did good service to the cause of cordon-training when he had an opportunity of doing so as correspondent of the leading journal; but why did he confine his praise of the system to only one form of it—the horizontal cordon? This is a very old acquaintance of mine now, and for edgings of borders merits every praise, always provided that the right stock be employed, which is of the greatest importance. I should not call 500 feet of such edgings “toy cultivation,” but look to it for a succession of the very finest table Apples in the world. The fact is, that in a large garden no single style of culture should exist, but various modes of training would give a better chance of good results.

Professor Du Breuil first tried cordons as far back as 1843 in the public gardens of Rouen. He began, not with the Pear, as many think, but with the Peach. The reason, he tells us himself, was the excellent one that the Peach tree, by the time it had reached the summit of an ordinary garden wall, had attained to its point of greatest production, and that it could not be maintained at that point, but must begin to decline from that date. Therefore he placed trees diagonally and closer together, and succeeded in realising all his expectations. Since that time a quarter of a century has elapsed; and if we may believe the leading authorities abroad, this form has remained pre-eminently that which produces the finest fruit and the heaviest crops, covers the wall the soonest of any, and is the simplest to manage. Why is this? Because the diagonal form, representing the angle naturally formed by a fruitful branch with the main stem, is in accordance with first principles. A vertical cordon has the defect of alluring the sap upwards; a horizontal cordon causes the branches to languish. Not that these defects are at all unmanageable, but they exist, while in the spiral and diagonal cordons they do not.

The single diagonal cordon is the “*cordon oblique simple*” of M. Du Breuil. I believe that I am responsible for this change of term, now generally accepted. Diagonal cordons are regularly advertised now. The reasons for changing the name were these. Every one knows what diagonal represents, while oblique is vague. Besides, the terms vertical cordons and horizontal cordons being in general use, diagonal was the nearest corresponding term to these for trees at an angle of 45°.

I must here re-introduce an old acquaintance, Professor

Gressent, whose works have, I was told last year, a very large sale, and are approved by the Minister for Agriculture in France. He says, “Diagonal cordons produce as much alone as all the other trees in any garden. They are the most easy to form, suit every kind of tree, and produce soonest the very finest fruits.”

M. Du Breuil commenced the system with this form, and it is still his favourite. To this may be added my own experience. I have for fifteen years cultivated all kinds of trees in this form with perfect success on the open wall, and for twelve or thirteen years in the orchard house. These are the oldest diagonal cordons, strictly so called, in England, and they are as good as ever this season, and full of promise. Such cordons should have a certain amount of space in every garden with a good wall, not for Peach trees, but for Pear trees especially. We planted last season some Pear trees for this form extremely well prepared by Mr. Rivers. Never have I seen better. Some were double-worked, the first of this mode I have tried. No doubt they will be a success. Trees double-worked as single diagonal cordons were not even heard of till very lately.

The cordon system has been gradually developed since its origin, a quarter of a century ago. It will soon become further modified, and, no doubt, scarcely then resemble what it was at first. This must cause some confusion in terms. M. Du Breuil himself tells us that when he went to see M. Grin's close system at Chartres, in 1856, he was so charmed with it that “he does not hesitate to recommend its adoption to the exclusion of all others.” The cordon of the present day, therefore, unites the leading ideas of these two systems, both founded on strict regularity of detail, as opposed to loose and irregular pruning, such as is so common here and abroad.

Cordons also mean close pruning; if not, the beautiful, regular “*coursonnes de Montreuil*” would have a claim to the term; but these, however symmetrical, require laying-in of long shoots, several successive tyings-up, and much removal with the knife. All this is unknown in the cordon *pur et simple*, which depends, and is founded on, the more modern theory of the close summer-stopping of the shoots, as opposed to the old system of hardly stopping them at all. In the old ways, and even at Lepere's, where there is the very best long pruning in France, the extremities of the leading branches were extended only to be elaborately suppressed; while in cordon-training, after the first few seasons, they are trained-in much as they extend. In loose long pruning, and in regular long pruning, the leading idea is to extend and to lay-in a greater or less length of summer wood. In cordon-pruning this is never done. Nor is cordon-training mere spurring-in, for it demands symmetrical and regular forms, and eschews completely any idea of forking branches. For these reasons all standard pyramids, and all bush trees in pots, are not cordons.

We must take cordon-training as it now is, modified by the lapse of twenty-five years. Still it retains the germ of the original idea, which idea rules modern fruit-culture, and that is, more trees and closer pruned, symmetrically

trained, evenly balanced, and with close summer-stopping as a prominent feature in all its modifications.

If we consider M. Grin's idea of a cordon as being unsuitable to our sunless and humid climate, we must remember that, like M. Du Breuil, he has advanced since he began years ago to the point of merely bisecting the stipular leaves. His original pruning was not so close as this, but the idea was the same—an idea, as Professor Gressent says, "founded on the normal principles of fructification"—viz., that of suddenly arresting and condensing the sap at the base of growing shoots and spurs.

I well remember, years ago, being at M. André Leroy's nursery at Angers pruning with M. Lévard, one of the very best pruners I ever saw. After a hard day's work, as we were leaving the gardens M. Leroy met us, and said he was thinking of sending Lévard to Chartres to study a new system of close pruning, of which he, M. Leroy, gave us some few details. M. Lévard did not like the new system, and never went to Chartres, and years after I found him still at M. Du Breuil's first style; but immediately on my return to Guernsey I cut back the whole of my Peach trees in every form to the new system, and have ever since carried it on, modifying it as occasion seemed to require, and never seeing M. Grin's trees till much later. The result of these experiments induced me to publish the "Modern Peach-Pruner," in which pruning to four leaves is recommended for the Peach, and working by alternate shoots. This was a combination of the *coursommes de Montreuil* with the close pruning of Chartres, and this last extended to four leaves, as a minimum, being of these regular systems a modified and combined view which contains the idea of a pure cordon, taking care that the leading branches do not fork, and be in some geometrical form. It is, however, the oldest regular cordon-training in this country.

This much may suffice to supplement, as I said before, the excellent work of the Editors; but does not the thought strike every one that it is owing to the poverty and confusion of our horticultural terms that much of this doubt as to the meaning of "cordon" has arisen? What, for instance, shall we say of such a term as the "irregular fan," when we know that a fan is not irregular, but the contrary? Why this dread of the introduction of foreign terms when we have the word *espalier* in such common use? What have we as an equivalent for "cordon," understanding it as we do? What word shall we employ, so as to be universally understood, to describe a tree with a single main stem and with horizontal branches and the ends turned upwards? Nevertheless, every one abroad would at once say a *palmette Ferrier*. But should the tree have a double-central leader (as we saw at the Paris Exhibition, and which is one of the neatest modes possible to control the sap), and the branches be trained obliquely, horizontally, or *à la Ferrier*, how should we designate it?

The word *palmette* is scarcely very happy, and we need not retain anything beyond a few expressive words borrowed from the French, but it is high time that horticultural terms were settled on some recognised basis.

We may rest satisfied that the orchard house of the future, if a lean-to, will have diagonal cordons planted against the back walls. Spiral cordons (one of the purest forms of cordon), will supersede all others but bush trees in pots for borders, when planted in groups of three or five. If the house is a span, then diagonals parallel with the house cannot be surpassed for beauty, or produce, or simplicity of training. On the open walls diagonal cordons of Pears and choice Apples will soon occupy their share, while low horizontal cordons for edgings for the borders will also be generally adopted. Some portions of a large garden being thus devoted to cordons, need not interfere with larger forms trained in other ways. In a good garden of suitable size something of every style of any pretension should have a place.

When cordon-training has been once fairly tried, its merits cannot fail to be recognised by English gardeners, who, in reality, are so superior in most things that any prejudice is out of place with a spirit of investigation and of fairness. For amateurs cordon-training is admirably suited. Its simplicity must recommend it. As to its injuring the life of trees, I can only say I have not found it so after these many years of heavy cropping.—T. BRÉHAUT.

SOME OLD PLANTS.

In page 46 is a query about a *Salvia* with the terminal leaves of a violet colour, found by "D. S." on the slope of the Col de

Tenda. I have no doubt that the plant is the Purple-topped Clary (*Salvia sclarea*), once so common in our gardens, but now rarely seen. It is a native of Syria and Italy. The inflorescence of *Salvia bracteata* has purple bracts, but it is a Russian plant, and cannot be the one alluded to.

There is another query, I believe, unanswered, about the plant called the Double Yellow Rocket, which is very fine. If those wishing for the information will look into any book on English botany they will find a plant called *Barbarea vulgaris*, or Yellow Rocket, of which the flower in question is a double state; the plant is, therefore, *Barbarea vulgaris flore-pleno*. It is a great favourite in cottage gardens, and deservedly so.

The Red Rocket, a neat, beautiful plant, is *Lychnis flo-scuculi*, or the Double Ragged Robin, which is rather scarce. This, however, must not be confounded with the purple variety of the Garden Rocket, which is *Hesperis matronalis purpurea plena*, and is so apt to die off that few can keep it. That truly beautiful plant the old dwarf Double White Rocket is plentiful in some localities. Cottagers about here who know how to manage it grow it profitably for market, as it is keenly looked after as a trade plant. The larger sort called the Giant, inferior, though fine, is often substituted for it, but a practised eye will detect the true sort at a glance.—THOMAS WILLIAMS, Ormskirk.

COCCOLOBA PLATYCLADA FOR DINNER-TABLE DECORATION.

PLANTS for the decoration of the dinner table at the present time are in such great request that every one suitable for that purpose is made use of. There are few plants better adapted for the purpose than that which I have named. It is an exceedingly interesting and curious-growing plant, introduced from Solomon Islands, with singular flattened branches, bearing oblong or hastate leaves, small whitish flowers, and fleshy fruits, at first red and then purple. Having used this plant myself, I can highly recommend it to those who may not have it. It succeeds well in an intermediate house. In colour it is of a lively green, and its habit is very graceful. The long flattened leaves are covered or rather edged more or less with small leaflets in an irregular manner. I never placed a plant on the dinner table that caused so much interest, or that looked better. It is also very useful for bouquets as it stands so well. J. GARDNER, *Aston Hall Gardens*.

POTATOES.

EVERY year convinces me more and more how very ignorant we are on the subject of the Potato disease; at the same time it seems to me that we do gain some insight into one fact—viz., that atmospheric causes, and especially wet, have much to do with it, and that to speak of any one particular variety as being free from disease is simply a fallacy. Some may be of harder constitution than others, but given the conditions favourable for the development of the disease, and no variety will be then able to withstand it. I am strengthened in this impression by observing the condition of my own stock this year. Last season (1866), I had a most disastrous time, and came very short in my supply. This season (1867), we were favoured in this part of England with a very fine August, which tended to make our harvest an excellent one; and as I took my Potatoes up before the September rains set in, I was saved the annoyance of seeing them spoiled, and have not had certainly a gallon of bad ones up to this time. Had I tried some of the many nostrums recommended, or grown one particular sort, or cultivated them in any exceptional way, I might have laid it to one or all of these things; but as I did nothing out of the way, and went on in the old routine, I can ascribe this result to nothing but the favourable weather that we had. Amongst other varieties I had a piece of the Salmon Kidney, the best late-keeping Potato grown, and this in August was seized violently with disease in the haulm. I immediately cut it down, much to the amusement of a market gardener (and a good one too), near me, who said it was no manner of use—that would not stop the disease. Fortunately for me it did, and so I hope to have good Potatoes until the new ones come in. I should add that I have for the last two years well lined my roots when I have taken them up, and I rather fancy that this has tended to keep them dry; dampness is, I believe, most favourable to the development of the disease.

In giving my estimate of varieties it must be borne in mind,

first, that I do not speak as a market gardener, do not take into account the cost and productiveness of the crop, but what is best suited for a gentleman's table—that is then, that I place flavour and quality first, appearance second, and productiveness third. The second point is that to which I have already alluded—that I do not hold to any variety as free from disease. Perhaps I should add that I grow my Potatoes in two separate places—one in an enclosed garden with rich friable loam, the other an open field with a somewhat heavier soil, but dry and open; and that hence, probably, my estimate is very different from that of others.

The varieties thus grown were—

VARIETY.	WHERE GROWN.	WHERE OBTAINED.
1. Early Ashleaf	Garden	Home-grown.
2. Myatt's Prolific Ashleaf	ditto	ditto
3. Early Don	Field	Downie, Laird, & Laing.
4. Coldstream Early	ditto	Hogg & Robertson.
5. Ross's Early	ditto	Mr. Thomson, Drem.
6. Lapstone	Garden	Sutton & Sons, Reading.
7. Late Lapstone or Daintree's Seedling	ditto	Home-grown.
8. Milky White	Field	Wheeler & Son, Gloucester.
9. Yorkshire Hero	Garden	Rev. W. F. Radclyffe.
10. Fenn's Onwards	ditto	Mr. Fenn, Woodstock.
11. Premier	ditto	Home-grown.
12. Salmon Kidney	Field	Rev. W. F. Radclyffe, and
13. Coomb's Favourite	Garden	J. Dickson & Sons, Chester.
14. Paterson's Victoria	ditto	E. Banks, Esq., Sholden.
15. Silver Seedling	ditto	ditto

1. *Early Ashleaf*.—There is little need to say anything about this well-known Potato. Its only fault is that it is a poor cropper; but I am told that Veitch's Early Ashleaf is of the same quality and much more productive. Much dependance can be placed on it for the first new Potatoes.

2. *Myatt's Prolific Ashleaf*.—An excellent Potato, very nearly of the same quality as the preceding, and a very good cropper. It is extensively grown about here by the market gardeners, and always commands a ready sale. Those who, like myself, prefer Kidney Potatoes, will give it preference to the early Round Potatoes.

3. *Early Don*.—I received this from Messrs. Downie, Laird, and Laing, and consider it to be an excellent Round variety. It comes in about the same time as Myatt's Prolific Ashleaf, is very prolific, white in colour, very floury, and of excellent flavour.

4. *Coldstream Early*.—Another Round Potato, very similar to the foregoing, equally mealy, and well flavoured; it is also very prolific.

5. *Ross's Early*.—This was very kindly sent to me by Mr. Thomson, of Drem, with a statement that, as he had to supply Potatoes for baking, he had found this to be the best variety for that purpose. He advised me to plant some large tubers whole, and said that I should be astonished at the result. I did so, and certainly the fine large tubers clustering round the stem were a sight. It keeps well, and is especially desirable for baking.

6. *Lapstone*.—I see nothing to alter as to what I have already said concerning this, the best of all Potatoes. It doubtless requires, to grow it in perfection, a light rich soil and a good climate, and would not probably succeed well far north; nor does it like wet. I have grown it very successfully this year, and have no hesitation in saying that there is no Potato that comes to my table at all comparable to it. For a main crop it is especially dependable.

7. *Late Lapstone or Daintree's Seedling*.—This partakes very much of the character of the preceding, but is not equal to it in flavour. I may be wrong, but it seems to have a little of the Fluke blood in it, and all that race I think very little of.

8. *Milky White*.—This now-celebrated Potato needs no commendation of mine. It well deserves its name, for it is the very whitest Potato grown. It is also prolific and a fair keeper.

9. *Yorkshire Hero*.—I do not see, either in growth of the haulm or in the tuber, the least difference between this and No. 7, and have heard the same remark made by other growers.

10. *Fenn's Onwards*.—An early Potato, kindly sent to me by "UPWARDS AND ONWARDS." The seed was Round, but the produce was pebbly—neither Round nor Kidney. It is exceedingly floury, and so very delicate in texture that it is not easy to peel it after it is boiled. It is, for a Round early Potato, an admirable sort.

11. *Premier*.—An early Kidney Potato; but I do not consider it as good as Myatt's Prolific, and have discarded it.

12. *Salmon Kidney*.—Known here as Deene Hall Kidney and Irish Kidney; the best of all late Potatoes. It is very peculiar in shape, being very full of eyes, but it keeps good up to the middle of June.

13. *Coomb's Favourite*.—This is nothing but a selected strain of the Lapstone; a very good one, but still nothing more than this.

14. *Paterson's Victoria*.—The best of all Mr. Paterson's much-vaunted seedlings, but without any great thing. It is large, rampant in growth, prolific enough, but not mealy—in fact, like all Mr. Paterson's, it is a field and not a garden Potato.

15. *Silver Seedling*.—A beautiful looking Potato with a silvery skin, but watery.

Such is my estimate. And now to the practical results. Plant early, and take up early. The disease generally comes on about the first week in August. If the weather be fine after that I should have no hesitation in leaving the Potatoes in the ground until September; if it set in wet I should be equally determined in taking them up. They will make no growth after the haulm is attacked by disease; and they will not be injured if taken up on a dry day and well limed before being stored. For my own use I intend for the future to grow the old Ashleaf, to be followed by Myatt's Prolific Ashleaf, Lapstone for the main crop, Salmon Kidney for late crop, and Ross's Early for baking.

I hope it will be distinctly understood that I only speak from my own experience, and that I believe locality and soil have a great effect on Potatoes, as with fruits, vegetables, and flowers of all kinds, varieties which succeed in one locality being utterly worthless in others. A notable example of this occurs in a contemporary a week or two ago, in which an amateur writes from Ireland of Lord Macaulay Rose as a flabby, dingy-coloured, badly opened, badly constituted Général Jacqueminot, while we regard it as one for which Portemer deserves a medal for raising.—D., Deal.

UNCOVERING ROSES.

FOLLOWING Mr. Radclyffe's directions, I covered my Roses in December with fern, and placed stable litter over that. We have had a most unusually mild season, and the Roses so far need not have been covered at all. I examined some of them the other day, and found them all making fresh shoots underneath the covering. Céline Forestier has shoots 3 inches long. Would it be well, as long as the weather continues mild and wet, to uncover them gradually, replacing the covering when the cold spring winds commence? I am afraid of the young tender shoots rotting-off beneath the mass of damp covering.—Q. Q.

[The season is comparatively mild, and Roses are forward here. I presume the Roses covered with fern are Teas and Tea-scented Noisettes. They may be uncovered this mild weather gradually; and if the frost return severely, they must be covered again till danger is over. I do not anticipate any more frost severe enough to injure Roses. In a few days I think of taking off the Asparagus haulm—a capital protection—from my Teas and Tea-scented Noisettes. If the new shoots are rotted "Q. Q." must have excluded the air, which should never be done. The Roses have three eyes; and if the centre eye, which breaks first, rots off, or is killed by the frost, it is of no consequence. The two other eyes will break in due time, and the best branch can be suffered to remain, and the other may be shortened back.

Céline Forestier here has a new flower formed. Roses will be early this year. The National Rose Show in my opinion is fixed too late, especially for amateurs and nurserymen who have small stocks. Hence the large stockholders carry off the prizes every year. In 1861 Mr. Turner wrote to me saying (June 20), "I am bloomed out." This does not conduce to national Rose-growing, the main object for which the Society was originated by the Rev. S. Reynolds Hale.—W. F. RADCLYFFE.]

THE SEED PODS OF ODONTOGLOSSUM GRANDE.

A PLANT of this Orchid, after producing five spikes of bloom in 1866, showed a pod, which grew to the size of a hen's egg. This continued on the plant all last year, and the blooms of last year have produced another pod, both of which appear quite green at this time, and have no appearance of ripening, although the plant is in robust health and preparing to bloom

next season. What I wish to know is, Whether the pods will perfect seeds, and how long I ought to allow them to remain?—H. M.

[One of the most experienced of Orchid-cultivators informs us that the seed pod of the *Odontoglossum* should be left on the plant until it bursts. As the pod in the above instance is still green, there seems to be no doubt it will perfect seed. The time occupied in ripening it varies from ten to twelve months, or even more.]

CRACKING OF CHASSELAS MUSQUÉ GRAPE AND STANWICK NECTARINE.

It may not be generally known, that the cracking of Chasselas Musqué Grape can be prevented by making a notch in the wood between the rod and the bunch. The operation should be performed immediately after the stoning of the berries, and the notch should be cut at least half way through the wood. The border at ripening time should be rather dry, and the usual amount of air ought to be given.

This Grape does with less stimulant at the roots than many other kinds; indeed, the Vines require soil specially prepared for them.

We have for several seasons past been successful in securing good crops of the Stanwick Nectarine, almost free from cracking, by applying the knife to the fruit-bearing wood. Immediately the fruit has begun the "second swelling," a notch is made into the pith, the same as with the wood of the Chasselas Musqué Vine. The fruit ripen off of a golden colour, the side next the sun is of a deep crimson tinge, and the flavour is of the finest description.

Last season a few of the fruit were allowed to crack before they were observed; the notching of the wood was then resorted to, and the wounds in the fruit soon healed up, and they swelled to a fair size, ripening equally well with the general crop, and being little inferior, except that they exhibited some scars where a little gum oozed out, and which was carefully taken off after it became hard. The wood thus notched is, of course, cut out at pruning time, to be succeeded by shoots left for bearing the following season. The tree thus receives no injury from the use of the knife. Previous to notching, to prevent the Stanwick Nectarine cracking, we tried every means we could devise, such as lifting the tree, placing it in a position on the back of a Peach house where the sun had greater power, keeping it dry at the roots, and giving an extra circulation of air, but with no apparent beneficial results. The crop always set as thickly as Gooseberries; all the fruit became cracked when of the size of Walnuts.

I should be glad to learn the experience of others with this excellent Nectarine, as it is seldom to be seen. It may be more successfully managed in orchard houses.—M. TEMPLE, *Gardener, Balbirnie, N.B.*

THE ROYAL HORTICULTURAL SOCIETY'S EXHIBITIONS FOR 1868.

At the risk of appearing captious in finding any fault with the just and interesting review by your contemporary of the programme of the Royal Horticultural Society for the coming season, I will venture a few observations upon it.

It recommends certain additions to the rewards offered by the Society to exhibitors, but I feel confident that this course will not secure the permanent and mutually beneficial arrangements which are aimed at. Better results may be obtained by some course in which the exhibitors and the Society shall have an interest in common, and by which exhibitions shall be self-supporting. We have evidence that such a course is possible.

Mr. Paul receives no prizes for his show of spring flowers, but the exhibition must repay him in some way. He finds, probably, that his reputation as a man of skill and enterprise is advanced by it, that Fellows and other visitors go to see it, and that trade naturally follows. Messrs. Waterer & Godfrey are also willing to show their plants without direct money reward; and I see in the Society's Almanack that Messrs. Lane are about to follow in the same footsteps. Here, then, are exhibitions, and very fine ones, made without any inducement in the way of prizes.

Nor is this all. In June a glorious display of Zonal Pelargoniums is to be anticipated, this being the growers' own day

when the "subscription prizes, in which they naturally take more than a passing interest [the italics are mine], will be competed for."

In these two classes of phenomena—the desire of nurserymen to exhibit without prizes, and the readiness of exhibitors to subscribe for their prizes, is the best hope for the future of exhibitions. Without much examination of details, it is pretty clear that shows as at present managed do not pay. The Royal has now one great show in lieu of three, and throws out hints of discontinuing even this one; and the Botanic has cut off all its spring shows. If more shows are cut off, Fellows will cut off their subscriptions, and then cultivators in their turn will be cut off from the opportunities now afforded to them of exhibiting their horticultural successes. The only safety lies in making shows self-supporting.

Judging from the Pelargonium example (is there not also a Potato sweepstakes coming off?) it appears not unreasonable to expect that wherever much interest is felt in the cultivation of a particular flower, whether on account of the profit it may bring to the seller, or by reason of the pleasure it may give to the grower, it is only necessary for the Society to provide the arena, and the competitors themselves will be ready to contribute the prizes; and in prizes contributed by themselves, the competitors will, as is truly observed, "naturally take more than a passing interest." People value most that which costs them something.

I have, therefore, written to the Council to propose that they shall invite the Tulip fanciers, the Pansy fanciers, and the fanciers of Carnations, Picotees, Dahlias, Hollyhocks, and Chrysanthemums, and their respective growers, as well as cultivators of Strawberries and Cucumbers, Peaches and Peas, to make up so many friendly matches among themselves, offering them every facility for contesting the championship in these various subjects. The Society ought to stand the expense of the bands, provide the judges' fees, and make all the arrangements, as their contribution to the entertainment, and perhaps it might not be too liberal a measure on their part if they contributed towards the expenses of the exhibitors, whether prizetakers or not, one-half the receipts at the doors.

Such a plan would be safe both for the exhibitors and the Society. Each exhibitor would invite all his friends to the Show; some part of their expenses at least would be recovered, and the Society would run no risk. And the Society ought not to run risks. Some ten or twelve years since it would venture everything on the chance of a fine day, and we all know the result. I hope that it has now grown wiser. I trust that the Council now feel that the worst misfortune that can befall a body is not to be able to pay its way, and that their imperative duty is to assure themselves that the arrangements they propose will not entail difficulties and disgrace upon the Society for which they are acting. To send round the hat periodically, and take the sense (ought I not to say, take advantage of the weakness?) of the subscribers concerning their mismanagement amounts to dishonesty, and the liberality of Fellows has been more than once thus imposed upon in days gone by.

If the Council, then, are persuaded that they already venture enough on prizes, I, for one, am for letting them alone. I greatly respect Mr. Micawber's maxims on revenue and expenditure. Income, £1. Expenditure, 19s. 6d. Result, happiness. Income, £1. Expenditure, 20s. 6d. Result, misery.

Have patience with me while I observe upon one other feature of your contemporary's recommendation. I have no wish to depreciate the value of the labours of the Fruit and Floral Committees. I believe them to be doing good service, and to be an essential portion of the Society's organisation, but I cannot help remarking, when it is suggested that the additional minor shows recommended shall be tacked on to the Floral and Fruit Meetings, that the general body of the Fellows cannot enter the Exhibition room until the Committees have finished their labours and their luncheons, and that immediately after the eating is done, the talking begins. The consequence is, that unless one is sufficiently bold and rude to walk about the room whilst Mr. Bateman is lecturing, one must rest content with the distant view of the flowers from the seat one happens to occupy, for no sooner is the lecture over than the plants are seized away from under one's eyes or nose, and there is such a general scramble to get them back into the vans again, as to suggest that somebody disagreeable may be expected to catch the hindmost.

Lectures are all very well in their way, and I have no doubt of their being very useful to good listeners and inquiring horticulturists.

The Fruit and Floral Committees have their own proper work to do. They were instituted to judge of, and to certificate, new and rare plants and fruits, and subjects grown at Chiswick. Add ordinary flower-judging to their work, and their speciality ceases. On the other hand, the Society has its gala day each week, and for this day such minor exhibitions would be suitable attractions. It already shows on that day examples of its own culture at Chiswick. Why should it not endeavour to supplement its own little shows with an occasional competition on the sweepstakes principle, and give us the opportunity of judging by comparison how far the Society is leading the world in gardening? If it cannot join in the sweepstakes, which, perhaps, it ought not, it can at all events stimulate its own cultivators to increased exertion by some little bonus each time that the merit of its own productions is pre-eminent. But the majority of the Fellows prefer small talk; and their daughters love to see and be seen, to listen to the band, and to listen to compliments, and these Mr. Berkeley never pays them. Mr. Bateman is more gallant, I own, but even his pretty speeches are, of necessity, too general to be very telling. Now, although I flatter myself I am too good a horticulturist to desire to convert our fine old Society into a mere fashionable resort, I confess to a weakness for pretty faces as well as for pretty flowers; and as I cannot think the brave old horticulturists of the palmiest days of the Chiswick *fetes* could have feared any ill results to their loved pursuit from bright eyes and gay dresses, from music and flirtations, I propose a time and place for the new shows which will secure these attractions.

Let us, then, Mr. Editor, have your support for holding minor shows of florists' flowers on Saturdays, or if not on Saturdays, on Wednesdays. On these days there is "no House," and surely our Senators are entitled to some consideration; there must be a goodly sprinkling of flower-lovers among them.

The time, however, for holding the shows might, if they provide the prizes, well be left to the exhibitors. If they think that snatched glimpses of their flowers in the Council room will serve their purpose better than prolonged examination of them in the conservatory, there is nothing more to be said, and I shall regret that I have already said so much.—ANOTHER F.R.H.S.

ORNAMENTAL AND FLOWERING SHRUBS.

Nothing in gardening is more remarkable than the immense number of Roses, Dahlias, Hollyhocks, Pansies, Chrysanthemums, Antirrhinums, Pelargoniums, Fuchsias—but I must stop—"The Gardeners' Year-Book," under the heading of "New Flowers of the Year," is conclusive as to the futility of enumerating all the genera, to say nothing of the varieties following in battalions. True, there are no species in "New Flowers of the Year," but the species which we see one year in the list of "New Plants," we may find in the next with a host of varieties all advancing by rapid marches from the "starry" to the "circular" and "globular outline;" some "excellent," others "distinct," "very fine," "beautiful." Then we have "Vice-President, a decided improvement on Chairman," "a colour much wanted," "a superb and beautiful introduction," "a fine variety for exhibition," "well adapted for bedding," and, to crown all, the "gem of the season." Indeed, so numerous are the varieties, so curious in name, and in garb so very rich, pretty, splendid, beautiful, delicate, and dazzling, that we are truly astonished at the assemblage, and wonder whence they have come and whether they are bound. The whence is found in "The Year-Book," but the whither who can tell? and we should never, perhaps, know, only sometimes among new flowers something is not equal to the description, or it may be worthless. I think it will be agreed, without a dissentient, that the number of new flowers raised and sent out every year by the trade in this country, as well as in France, Belgium, Holland, and Germany, is very remarkable. Even the Japanese Chrysanthemums, though the idea of those "Ragged Jacks" ever being of any use was ridiculed upon their introduction, on being subjected to British improvement have been influenced by it, and the "first fruits of a rich harvest" have resulted from Mr. Salter's labours. Many interesting varieties have been raised at the Versailles Nursery, and are there to be seen; some, "D., Deal," says, being like "penny spiders," paper cuttings, or having spots like Orchids, and all curious, which latter I should think they must be if at all like the parents. They will, most probably, supply a gap, but I doubt if the gap will yet be well filled.

It was in 1834 or 1835 that the Chinese Chrysanthemum, at that time a "Ragged Jack," was subjected to British improvement, and many fine varieties were raised at Oxford and at other places in England, and in the Channel Islands, especially Guernsey, and we have seen this once starry flower brought to a state of great perfection by the persevering skill and industry of the hybridiser, whilst the splendid specimens seen at our winter exhibitions, show the improvement not to be confined to the raising of new varieties, but to be equally manifested in the art of culture. The consequence of this improvement, not only with the Chrysanthemum but with other plants as well, is a demand for new plants, which is met in two ways:—First, by importations from the Continent; and secondly, by the vast number of hybrids and cross-breeds raised by nurserymen, amateurs, and gardeners in this country, as well as by our neighbours on the Continent.

From the date of the establishment of flower shows this demand has gone on increasing, and developed such extensive ramifications that many think it would be well if all new varieties were subjected to a strict scrutiny before being sent out, thus saving money, time, labour, means, and disappointment. This, however, would not prove of any great avail in stopping the rage for new flowers. The new and rare is the prize most coveted, and, no doubt, is a most lucrative business to those most intimately connected with it. So long as the fashion is all for new plants, so long will all lovers of gardening seek to possess themselves of something more rare and beautiful than their neighbours. Thus flower shows by exciting in gardeners, professional and amateur, a spirit of emulation, have done much towards improving the science of floriculture.

Now, without wishing in the slightest degree to discourage or diminish the prevailing and increasing taste for flowers (for their care is a great source of health and enjoyment to many not as yet imbued with the same ardent taste for shrubs as they have for flowers, because a like spirit of emulation has not been provoked by the metropolitan, still less by the provincial flower shows), I am in the firm belief that the agency so productive of a taste for flowers, would be equally effective in promoting a taste for ornamental and flowering shrubs. I am certain that the offering by the London societies of prizes commensurate with the object, would secure a response worthy of the occasion, and secure a highly instructive and desirable exhibition. There cannot be a doubt, that once a spirit of emulation excited, a taste for shrubs equal to that for flowers would spring up, and spread by the provincial societies throughout the country. Once create a taste, and the demand will increase, and proportionate supplies will be forthcoming. This we know to be a fact, as only last spring Mr. William Paul exhibited a splendid collection in the Royal Horticultural Society's gardens, thereby proving that we have only to encourage a taste and demand for shrubs, and we shall have caterers ample for our wants.

Though the principle of hybridisation or cross-fecundation was known in 1717, in the time of Bradley, yet it was not until the year 1830 and subsequently that any one thought of applying it to produce new and more beautiful varieties of flowers, notwithstanding that through its agency remarkable results with Apple, Pear, and other fruit trees had been obtained by practising it in times prior to 1830. Florists, even, before the establishment of flower shows never thought of cross-fecundation as applicable to the production of new and beautiful varieties of flowers, but by the most extraordinary and unexampled patience were content to wait till in self-coloured varieties some accidental combination of favourable circumstance of soil, climate, and culture induced a "breaking" of colour in the parent, and a variation thus attained was transmitted in a greater or less degree to the progeny.

The march of improvement in flowers dates chiefly from the establishment of flower shows. The attention paid to the raising of fruits bears no comparison to that bestowed upon the raising of new and beautiful plants or flowers; it has for a long time slept as regards the majority of professional and amateur gardeners. Though it may at times have made itself active, yet it is only now beginning to arouse itself from the long sleep it has taken since the days of Knight; but we now have the taste for fruits revived, not to any great extent more than formerly by horticultural societies, but by the introduction of orchard houses, and the greater facilities afforded by cheap glass for proving the seedlings. It is true there has been a great influx of Pears and other fruits, but many are utterly valueless, all our old varieties still holding their ground, and every day becoming more prominent. That we are sadly

deficient or have been much behind our progenitors in the art of raising new fruits, I think the small additions of improved varieties (as compared with flowers), that have been made to the lists until very recently afford abundant testimony. Happily we are commencing what I believe to be quite a new era in fruit culture, having Mr. Rivers's results with Peaches and Nectarines; Mr. Ingram's and Mr. Hussy's with Pears, and numerous others. That we owe much to such men as the raiser of Lady Downe's, the Duchess of Buccleuch, and other Grapes, the raisers of the Victoria Nectarine and the Victoria Pear, we must all admit, but there is room for still greater results. I think we have only to wait a short time ere we have an equal abundance of improved fruits, as we have of improved plants and flowers, of which there is none too many.

It is hardly necessary to point out the small amount of favour shown towards shrubs by the different floral and horticultural societies. There is not a prize for hardy shrubs in any of their schedules: hence the spirit of emulation has not been excited in gardeners, and they have not begun to think of improving the different kinds of shrubs. It rests with the horticultural societies to create a taste for arboriculture, by awakening the attention of those skilled in hybridisation to the great improvements which may be effected in shrubs; and were the same favour accorded to shrubs as to plants, I think, notwithstanding all that might be said against them on account of the ragged and starchy outline of their flowers, the taste for them would spread, and that improvement would be the result.

Prizes might be offered for the best collection of hardy shrubs in flower, for those remarkable for their foliage, and for those producing fruit, according to the time of year, they being in pots of a certain size, for it is desirable that good cultivation and not means should receive encouragement. The majority of shrubs can be grown in 11 or 13-inch pots to a size sufficient to show their characteristics quite as well as if seen in the open ground. It is not necessary to bring a tree in order to exhibit its fruit, hence it would answer quite as well to exhibit a branch to show a tree's foliage, and a branch would serve equally well where the beauty consists in the flowers. Prizes, then, for shrubs in pots and for cut specimens are all that is required to promote a taste for arboriculture, which I would like to be more on a par with floriculture than it now is; indeed, I should like to see every owner or possessor of a garden have a border or shrubbery of choice shrubs, which would be a source of lasting pleasure.

It is not my intention in this communication to treat of subjects that attain the dimensions of a tree, but I shall confine myself to shrubs which usually do not exceed from 10 to 15 feet in height, though they may in a favourable soil and climate attain much larger proportions. They are those that should stand nearest the dwelling, and be of the dwarfer and most beautiful kinds. They should be selected so as to accord with the style of the building, and in planting particular attention should be paid to the shades of green, and the effect that the plants will produce when they are in flower. The effect will be in a great measure produced by the contrast of the shades of green, but if the appearance at the flowering season be not also considered, the effect at that time will not be good. Shrubs having a grey or bluish tint when behind or amongst those of a yellow or bright green hue are thrown into the distance, whilst those with light and small foliage are best planted beyond those whose foliage is broad and fixed. Those with variegated foliage should be employed to relieve the sombre and uniform appearance of evergreens, and those that flower or retain their berries in autumn and winter may be used for a like purpose. Sombre-looking shrubs should lead to the most beautiful or gay, and light coloured foliage should appear among evergreens. The most beautiful shrubs should have the most conspicuous and prominent positions, the shrubbery where it projects being planted with those most distinct and brilliant. The design, though bold, ought to be rendered free of all harshness and abruptness by a judicious arrangement of the colours, blending easily one into another, and not a shrub should be planted that will not add to the effect and harmony of the whole. In planting in regular order and at equal distances it is not desirable to form a shrubbery of recurring varieties; if more than one of a sort be planted, it would be well to group it in one place so as to give effect in various parts by a mass of one colour whether consisting of foliage or bloom.

A shrubbery should not be too much crowded, as the beauty of the plants cannot be displayed when they are planted so closely together as to be drawn up into unnatural shapes.

Attention should be paid to height, for it is destructive of effect as well as to the plants' growth to place the tallest next the walk or nearest the eye, and the dwarfiest at the back or behind them; but much may be done towards giving an undulating appearance by planting the tall shrubs together in clumps, and the dwarf ones as well, proceeding gradually from the lowest to the highest shrubs, and again from the highest to the lowest. It is desirable in planting to bear in mind that effect does not depend on the rarity of the plants, but on a selection of those succeeding each other in their blossoming or the ripening of their various-coloured fruits, which latter add materially to their beauty when the flowering is over.—G. ABBEY.

(To be continued.)

ROYAL HORTICULTURAL SOCIETY'S EXAMINATIONS.

THE result of the last examination of gardeners for certificates, held at the Royal Horticultural Society, South Kensington, on the 17th of December, is as follows:—

		Vegetable and Fruit Culture.		Floriculture.	
W. Spinks.....	Chiswick Students.	First Class	First Class	First Class	First Class
B. Wynne		ditto	ditto	ditto	ditto

GALVANISED WIRE TRELLISES.

THE trellis of Mr. Williams, of Woodland, that I wrote of showed no sign of wearing, neither was there any sign of canker or gum. If Peach and Nectarine trees are tied tightly to wires or nails, they will throw out gum or canker. Two inches from the wall is too far for a wire trellis. Peaches and Nectarines do not like draughts of air behind them. I tie all my Peach trees with bast instead of shreds, which harbour pests. The plan is inexpensive, and neater than shreds. I use cast-iron nails; and instead of drawing them and leaving holes I break them off. They are very cheap.—W. F. RADCLIFFE.

ENTOMOLOGICAL SOCIETY'S MEETING.

THE first meeting for the present year was held at Burlington House on the 6th of January, Sir John Lubbock, Bart., F.R.S., President of the Society, being in the chair.

Amongst the donations received since the last meeting were the "Proceedings" of the Essex Institute of Natural History held at Salem, United States; the Ferdinandeum Institution of the Tyrol; the Netherlands and Moscow Societies; the Linnean Society of London, &c.

The Rev. Douglas Timmins exhibited three interesting varieties of the Queen of Spain Fritillary Butterfly, *Argynnis Lathonia*, in two of which the wings were of abnormal form and size, and in the third the black markings were greatly suffused; also a specimen of the magnificent *Charaxes Jaisius* reared in England. Mr. F. Smith exhibited several specimens of a large species of Wasp belonging to the exotic genus *Polistes* (and closely allied to *P. biguttatus* and *versicolor*, natives of Brazil and the West Indies), of which five individuals had been taken alive in the course of the summers of 1866 and 1867 at Penzance, by Miss Carne, in the window of the same house. Mr. Smith was unable to conjecture how such insects could have been introduced into this country.

A note was read from Mr. Colville as to the geographical locality of the two species of *Papilio*, *Phorhanta* and *Epiphorbas*, natives of Mauritius and Madagascar. A note was also read from Captain Leudy as to the introduction of the eggs of *Bombyx Atlas* from China, with the view to their being employed in silk culture. A letter from Herr Schickendanz was communicated by Dr. Burmeister from Buenos Ayres, containing a description of a new and remarkable genus of Lamellicorn Beetles in Brazil, belonging to a group hitherto only known as peculiar to the shores of the Mediterranean, its position being between the genera *Macrophylla* and *Pachypus*. It had been captured on the flowers of a leguminous plant, and it was proposed to be named *Burmeisteria mirabilis*.

A report by the Rev. G. Richter, Governor of the Central School at

Koerg in the East Indies, was read on the destruction of Coffee trees by the larvae of a Beetle named the Coffee-tree Borer, and on the means of preventing its ravages. Specimens of the injured wood and insect were forwarded: the latter proves to belong to the family Cerambycidae, and has been described under the name of *Clytus maccaensis*.

The Secretary made some observations on the law of priority in nomenclature as applicable to certain species of Hymenoptera from Australia, of which short descriptions had been printed and circulated by the Rev. F. W. Hope, but which had never been regularly published and sold; the insects having subsequently been described and figured by other authors with other names, which under the circumstances Mr. Dunning considered as entitled to priority over Mr. Hope's names.

Mr. MacLachlan exhibited a very beautiful species of Caddice Fly new to this country, which had been taken at Bishops' Wood, in Staffordshire, by Mr. Chappell, of Manchester. It is the *Neuronia clathrata* of Kolentati.

Mr. Hewitson communicated a critical revision of Mr. Wallace's memoir on the Pierideous Butterflies of the Malayan Archipelago, recently published in the Society's Transactions.

A new part of the Society's Transactions was announced to be ready for delivery to the members.

FLOORS CASTLE.

[THE following notes on this magnificent residence were written by one of our correspondents in the autumn of 1865, and should then have appeared. Public attention, however, has recently again been directed thither by Her Majesty's visit to its noble owner, and also by Mr. Rose, the very able gardener there, being appointed to the management of the Royal Gardens at Frogmore; so we now place before our readers an account of the garden and grounds, and would more especially call attention to the fine range of glass houses, presenting features not often met with, and well worthy of being copied.]

To the tourist from England who enters Scotland for the first time by the East Coast route, the tameness of the scenery at the boundary of the two countries is disappointing, the town of Berwick itself having little to recommend it, while the Tweed, the stream of whose beauty poets have so often sung, seems only to resemble a wide shallow canal, especially when it is low water. The country, too, is more interesting to the farmer and utilitarian than to the lover of Nature, as good farming, large fields, and straight fences, with few or no plantations of any importance, give rather a bleak than a clothed appearance. But follow that river up its course, and then its real character and beauties appear—its clear limpid stream, now expanding itself between meadows of the richest green, now hemmed in between high banks overhung by woods, both natural and artificial, with ever and anon a rock opposing its rugged base to the onward course of the stream, which murmurs at the impediments in its way. The scenery on the banks is likewise ever changing. Now and then is seen a modern mansion replete with all the comforts the wealth of the nineteenth century can command; while, externally, well-dressed grounds, trim fences, and good roads, attest the advance which taste and industry have made; and probably not more than a gunshot from this residence may be described the remains of some feudal fortress, with its keep and ponderous walls, interesting by its historical associations. Farther on a less imposing memento may remind the traveller of an encounter between the people of the countries on the opposite banks of the river, or, perhaps, most interesting of all, he may meet with the remains of some religious edifice, which even in its ruin shows that the skilled artisan of the present day is in many respects inferior to his brother craftsman of some four or five centuries ago, as the adornments among the ruins of Melrose Abbey, for instance, bear witness. Leaving the tourist, however, to journey through a district of such historical and poetical interest, let us retrace our steps a few miles downwards from Melrose, and we find ourselves in the immediate neighbourhood of a residence almost regal in its proportions and remarkable for its beauty.

Floors Castle, the principal seat of the Duke of Roxburgh, is beautifully situated on the left bank of the Tweed, and about a mile from the thriving town of Kelso. The present structure is a castellated building of large dimensions, which was considerably improved and enlarged a few years ago, the original structure having been built from designs by Vanbrugh, soon after the beginning of the last century. The approach from Kelso partly passes through and partly skirts a wood of large and healthy Oaks, Silver Firs, and other trees, ample space being allowed for the carriage road, as well as for its margins. The mansion stands on a gentle eminence, the ground receding

from it towards the south and east, the approach alluded to being from the latter direction. Making a slight *detour* the visitor is carried to the north side of the building, which, as in most other residences of a like character, is made the carriage entrance; but my object being to visit the garden, which is a little to the west of the mansion, I contented myself with a hasty glance at the noble residence. I was astonished at its extreme freshness of colour, the pale freestone looking as if it had not been more than a week out of the quarry, and this circumstance, coupled with the emerald green of the turf, and the healthiness of the vegetation around, would imply a purity of atmosphere and fertility of soil not often met with.

At a convenient distance to the west of the mansion is the new kitchen garden with its various appurtenances. Some fine timber trees, interspersed with shrubs, form a sort of link between it and what may be called dressed ground. There is also a very extensive area on the north side of the mansion, and a much larger space on the south and south-eastern sides; in fact, the extent of what may truly be called lawn would appal any one not conversant with mowing machines, for apparently every inch of the space seemed excellent grazing land, capable of producing any number of good crops without diminution from the dry weather, which in the south of England is sometimes such a drawback; but here winter only would seem to cause any cessation of growth. Leaving this beautiful scene, a very few minutes' walk brings us in sight of a garden wall, and the first look confirmed what I was led to expect from preceding objects—that the kitchen garden and all its appurtenances are entirely new. I now made the acquaintance of Mr. Rose, the highly intelligent gardener, a difficulty easily overcome where courtesy and hospitality are so abundantly exercised as it is by him.

A cursory survey enables us to see a kitchen garden of four acres or more in extent, of a long rectangular shape, and surrounded by high walls, on each side of which are planted suitable trees; while the southern side of the south wall is covered, or partly covered with glass. Some intermediate ground, partly dressed, unites this part of the garden with a wood a short distance still farther to the south, but too remote to do any harm by its shade. Mr. Rose's cottage, situated at the north-eastern corner of the garden wall, is well placed, so as to look into the kitchen garden, a new flower garden, and an extensive range of forcing and plant houses, as shown in the plan, and of which the top is the north side.

The kitchen garden, with its slip on the south side, forms the western portion of what may be called the gardener's domain, his cottage being at the north-east corner. Separated from the north garden wall by a convenient space is the range of glass structures referred to, the house at the back, No. 8, being about on the same line as the north garden wall, and the other houses all at right angles to this. Some trees shelter the whole, as well as conceal the heating apparatus and various back buildings. These glass structures are all span-roofed, and excepting the back of the long one, No. 8, which is a blank wall, all the sides of the others, as well as the front of the long house, are glass almost to the ground; and being all of a size in both length, width, and height, they unite to each other and form a noble and attractive whole. From what few observations I was able to make, it would appear that a multiple of 20 is the ruling figure in the arrangement, each house, including the back one, being 20 feet wide; the interval between the houses is also 20 feet, and the length of each 60 feet, making the back one 260 feet long. I am not sure whether the doorways to the long house, No. 8, are enclosed by ornamental porches or not; but I believe they resemble those entering the other houses from the front, each being simply a good-sized door in the centre of the gable, which also exhibits some suitable ornamentation, but not such as to detract from the appearance of the structure as a whole. The lantern at top gives sufficient air at that part, and ventilation is also afforded by openings at the sides. The houses are heated by hot water, and from the number of pipes in each house the heating, no doubt, is very effective.

A broad path passes through the centre of each of the houses numbered from 1 to 7, and communicates with the back house; and to support the roof, a series of cast-iron pillars, arched at top, and united by braces to the rafters, as shown in the accompanying section, give both strength to the building and beauty to the interior, for they form a sort of archway on which Vines or climbers are trained, and as they are only underneath alternate rafters, they are not too numerous to be in the way. I am not

certain whether this arrangement existed in the back house or not, as the pathway there is of a serpentine character, but so arranged that the curves approach the south side at each place where a door enters into one of the other houses. This pathway is upwards of 4 feet wide. The house is planted entirely with hardwooded plants of large size, as Camellias, Acacias, Azaleas, and New Holland plants of an ornamental character, the back wall and roof being covered with climbers, and the whole in the most excellent health, forming a shrubbery which at no distant day threatens to block up the path; but judicious pruning will, no doubt, keep it in order for very many years. The extent of this house, 260 feet in length, by 20 feet wide, will enable the reader to judge there was ample space for a great variety of plants, and the serpentine form of the pathway brought the visitor in presence of a fresh set of plants at every turn, which would not have been the case had the path been as straight as in some corridors leading to conservatories or other objects at a distance. The curves are uniform and easy.

The space between each house is just the width of the house itself—i.e., 20 feet. This space constitutes the Vine border, where the houses are devoted to the culture of that fruit or of the Peach, and probably the climbers of the plant houses luxuriate in the like open space. Where Vines are grown they are planted inside, the whole of the floor of the house being also reserved as a border. I am not sure whether any bottom heat was supplied or not, but a drain ran along the centre of each outside border, and rubble stone almost to the top received what superfluous water might fall on the borders. These slightly inclined from each house to the centre, where the drain and rubble stone existed, and I am not sure but shutters were provided to carry all the rain water there. Be this as it may, the excellent condition of the fruit gave unmistakable tokens that the border and all its accompaniments were just such as the Vine delights in, as most excellent fruit were hanging in great abundance in all the houses where the Vines were growing. The Peaches, of course, were over; but the condition of the trees showed that they, too, were in the best possible health and bearing. I regret that the hurried manner I passed through this fine range of houses in order to again reach a train prevented my inquiring into the various details as I otherwise would have done, but Mr. Rose kindly furnished me with the following:—

No. 1 was a plant house devoted to hardwooded plants, many of which were, of course, out of doors at the time of my visit, and their place for the time being was occupied by showy flowering plants suitable for the season.

No. 2, Peach house. Of course the crop here had been gathered some time, but there were plenty of excellent fruit from a glazed Peach wall, forming the southern boundary of the kitchen garden.

No. 3, Muscat house. Excellent fruit of several varieties. Mr. Rose was trying some experiments on stocks. His

opinion that the Muscat of Alexandria would always retain as high if not the very highest place in collections of Muscats, seems to be generally confirmed by that of other growers.

No. 4, Plant stove. There were some good specimens of plants of various kinds, including Marantas, Crotons, Aloegasias, and Allamandas, all in good health and well arranged for effect.

No. 5, Vinery. The Vines were mostly Hamburgs, of which there was a considerable variety, all in excellent order, and I noticed the Black Muscat of Alexandria, or Muscat of Hamburg, as it is commonly called, in better condition than we had ever before seen it. A white Grape, called Catawba, was also a favourite with Mr. Rose; but I regret not remembering precisely its features. Calabrian Raisin was in promising condition to ornament a dessert at Christmas.

No. 6, was a late vinery. Here Mr. Rose had Lady Downe's, West's St. Peter's, and Alicante in excellent order, and one or two others on trial; but he considered that a very good supply might be had by growing only three or four kinds—namely, Black Hamburg, Muscat of Alexandria, Lady Downe's, and another. He was of opinion that each variety should have a house to itself, and considered that none more wanted this than Lady Downe's. The Vines in all these houses were young. All were bearing full and heavy crops, and were healthy, luxuriant, and without the least appearance of red spider or any disease. The house, having a span roof of such an extent covered with fruit, had a very fine effect.

No. 7. This, like No. 1, was a plant house, but for the soft-wooded plants. It was well filled at the time of my visit with plants in flower, for the great bulk of the Chinese Primulas, Cinerarias, and Pelargoniums were in cold pits elsewhere.

Having roughly and imperfectly described these houses and their contents, I should remark that a broad terrace walk 16 or 18 feet wide passes along the front of them, the doors in the ornamental gable end of each house opening upon this walk. To the south of this walk is a geometrical flower garden on grass. The panel containing the flower beds is somewhat longer than the front of these houses, 260 feet, by gaining some feet at each end. This panel, a square, or nearly so, is sunk on three sides, so that the terrace walk commands a good view of the flower beds; and as the extent affords ample space between each bed, their contents were seen to every advantage. I need hardly add that the beds were all planted with the choicest plants used for such purposes, and that the only failure, or partial failure, was in a Verbena of that intermediate class related to Velvet Cushion which only succeeds well in a few places.

The terrace walk just mentioned unites with others, carrying the visitor forward to the mansion. Groups of choice shrubs were judiciously planted by the way, and these and the rich verdure of the turf, as well as of the timber trees left in groups here and there, promised that the present appearance of new or rather extended grounds, will not be of long

Plant and Fruit Houses at Floors Castle.

duration. As it is, there is no lack of anything to give importance to a place that is connected with so many historical associations. The ruins of Roxburghe Castle are but a short distance from the front of the mansion, and in the park be-

tween the two, a Holly bush is said to mark the spot where James II. of Scotland was killed by the bursting of a cannon. A little higher up the Tweed, the Eildon Hills, are seen peeping over the trees.

NOTES AND GLEANINGS.

At the Royal Horticultural Society's meeting on the 18th inst., there is to be a ballot for twenty-five lots of plants.

These consist of seedling hybrid Caladiums, Peperomia marmorata, Bertolonia guttata, Cissus porphyrophyllus, and several

other stove plants with ornamental foliage; *Camellia reticulata*, *Lilium auratum*, a few other choice greenhouse and hardy plants, together with *Berberis stenophylla*, a hybrid shrub with very ornamental rich apricot-coloured flowers; and of Conifers, *Thuja compacta*, *Thujaopsis borealis glauca*, and *Retinospora pyramidalis*. Fellows intending to take their chance in the ballot should send in the numbers of the lots they may select, on or before Tuesday, the 11th inst., which, we may remark, is also the day of the Annual General Meeting.

— THE Challenge Medal of £20 in money at the option of the winner, offered by Mr. James Bateman, F.R.S., to the exhibitor gaining the greatest number of marks for Orchids at the meetings of the Royal Horticultural Society during 1866-67, has been won by Mr. James Anderson, gardener to T. Dawson, Esq., of Meadow Bank, Uddingstone, by a large majority of marks.

WORK FOR THE WEEK.

KITCHEN GARDEN.

ATTEND to the due preparation of ground for crops in general, but beware of carrying on any operations while the soil is wet; better be a fortnight too late with any given crop. Where kitchen gardens are composed of light sandy soil they are better dug or trenched some weeks before the ground is wanted for certain crops, especially Broad Beans, which like a firm hold of the ground. *Cauliflowers*, have hand-glasses ready for the plants in pots; enrich the stations very much, adding fresh loam if it is at hand. Under each hand-glass turn out four strong plants from the pots, one in each angle, soaking well with liquid manure previously. *Cucumbers*, as there are many amateurs and gardeners who have not the advantage of a pit for growing their Cucumbers, the following way of forming a bed may be new to some, and will be found much better than making one wholly of dung, as it will not sink so much, nor take so strong a hue to keep up the heat. Mark off on the ground a space 1 foot longer and wider than the frame, next build up to this size with faggots of stent brushwood to the height of 2 feet, then lay a row of faggots 18 inches in diameter along the back, front, and ends for the frame to rest upon, placing them close and firm, leaving the interior space to be filled up with fermented dung and leaves as a foundation for the soil. *Horseradish*, plant if not already done, dibble it in in rich light soil from 1 foot to 15 inches deep. *Sea-kale*, let this and *Rhubarb* intended for next year's forcing be planted immediately in rich trenched ground; throw up a hillock of old tan, ashes, or sand around each crown to coax it on through the vicissitudes of the weather during this month and March. Thoroughly drain any portion of the garden which exhibits the least appearance of requiring such an operation. Where water is apt to stand on the surface through the puddling properties of heavy soils, try to improve the texture by a dressing of sand, ashes, lime rubbish, charcoal dust, &c.

FRUIT GARDEN.

Finish all pruning in this department without delay. Gooseberries, Currants, Filberts, and all standard fruit trees ought to be kept clear in the centre, so as to have a full surface exposed to light inside as well as outside.

FLOWER GARDEN.

As before observed, see that all planting is completed forthwith. Improve as much as possible outlines of every kind. Plant fresh masses or groups where necessary, and introduce specimen plants where fitting opportunities offer. Much mischief is done by planting single specimens in recesses. These should be carefully preserved as a general rule, to give deep shadows and to throw the prominent features into bold relief. If frosty weather should set in every available means must be adopted to protect Tulips and Auriculas. At this season mice are apt to be very mischievous amongst Polyanthus when kept in frames by eating the hearts of the plants; they must, therefore, be trapped. When the weather is sufficiently fine lose no time in planting Ranunculuses. These beautiful flowers delight in a cool subsoil. Seed may now be sown in pans or boxes; the compost of decayed leaves and sand having been well watered the night before the seed may be scattered rather thickly, pressing it gently on the surface; cover very slightly. If a proper quantity of compost is not prepared lose no time in mixing it, at the same time keeping a vigilant watch for all injurious insects. It will soon be time to place Carnations and Picotees in their blooming pots. Plant out biennials in masses where requisite. In borders the re-arrange-

ment of perennials had better stand over until the latter begin to bud in March. A calculation should now or soon be made as to how far the inmates of cold frames will supply the demands to be made upon them. Damp, no doubt, will be found to have reduced the number of some kinds. Strong plants, or store plants, of Verbenas, Fuchsias, Petunias, Heliotropes, Salvias, and Calceolarias, which had become well established in the autumn, should be removed forthwith to some of the houses or pits at work. These will quickly furnish abundance of early cuttings, which should be slipped off and propagated.

GREENHOUSE AND CONSERVATORY.

As the season advances give more air to these houses. See that suitable composts are ready under cover for potting and sowing seeds. Some of the hardwooded plants may now be propagated by cuttings where a gentle bottom heat can be kept up. As charcoal is now allowed by all to be of use to plants, endeavour to have a supply of it at hand for mixing with the soil before the potting season arrives. The early-forced bulbs will now be out of bloom in the conservatory, and should be removed to some sheltered place, from which frost is excluded, in order to ripen their foliage, and other plants may be introduced from the forcing pit. *Bibiscus*, *Clerodendrons*, *Justicias*, and other half-stove plants which flower in the conservatory may be pruned, and some of them placed in a higher temperature, but they should not be potted until they begin to grow freely. A few *Neriums* and *Hydrangeas* may be forced into early growth for this house. A gentle heat would now benefit the Chinese *Azaleas* for early flowering. Continue to give as much air to the greenhouse daily as the state of the weather will admit of, and see that all the plants are watered regularly. The great point is to keep these plants from growing early.

STOVE.

Many of the Orchids that have been kept dry during the winter should now be prepared for a fresh growth, by picking out as much of the dry materials in which they have been growing last year as can safely be done without injuring their roots. All decayed roots should be cut back to where they are fresh. Let the dry pieces of peat be well saturated before you add fresh. The following stove plants will flower freely in a temperature of 45°:—*Poinsettia pulcherrima*, *Aphelandra cristata*, *Justicia speciosa* and *coccinea*, *Eranthemum pulchellum*, *Begonia octopetala*, *Phajus grandifolius*, *Euphorbia jacquiniiflora*, *Echeveria gibbiflora*, *Gesnera elongata* and *lateritia*, *Pancratium amenum*, and *Ardisia crenulata* (for the berries).

FORCING PIT.

Continue to introduce fresh supplies of plants as the former ones are removed to the conservatory; also other plants from which you wish to obtain an early crop of cuttings. Common plants that do not promise much bloom should be at once discarded to make room for others. Failures of this nature always occur more or less in early forcing.

PITS AND FRAMES.

Here, if the number of plants required for bedding-out is considerable, there will be plenty of employment for all hands. The whole of the autumn-propagated plants must be potted-off without delay, so as to have them well rooted and turned out into temporary pits by the 1st of April, in order to set the pots at liberty for a second lot of plants, which should now be coming forward in the propagating frames. Sweet Peas, if wanted to bloom early, must now be sown in pots, in heat, for transplanting.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN AND FRUIT DEPARTMENTS.

THE weather being stormy, potted *Cucumber* plants in a dung frame, carrying them covered up in a basket into a warm shed and back again, and used water at a temperature of about 100°, in addition to warmed soil, so as to give them as slight a check as possible. A chill or a check now will often affect the plants for the season. These are more easily managed in places heated by hot water; and where the work can be done inside of a house, or in a pit large enough to work in, such care is not required, but we often raise the spring plants in a small hotbed, as we could not afford enough of heat to a hot-water pit without giving more heat to other places than we want, and we therefore would have to use more fuel than absolutely necessary, but which would be all very well when the place was

filled with large plants of Cucumbers. In their young state, a good many can be kept in a dung frame until they have attained a fair size; and though we have not a word to say against hot water, still we think that young Cucumber and Melon plants come more robust and healthy in a dung-bed frame. Of course, there is the sweet heat to be secured, and steams and damps to be avoided; but then there is no firing to be given, and somehow there is that in the heat of dung and leaves when perfectly sweet that no other heat can give so efficiently. The best way for securing plenty of sweet top heat is to have the outside of the frame well banked-up, so as to make the sides of the frame conductors of heat. Wood is, no doubt, a bad conductor, but still when a warm substance is long enough against it, it will conduct in time, and continue to do so, so long as the heat remains in the banked-up material. To secure this in front, means should be taken to throw the rain off that falls on the glass, otherwise that will go down by the sides of the frame and even penetrate into the bed. For want of a better, two slips of wood fastened together at an angle, make a tolerable spout for taking away the moisture that falls on the glass.

In the Peach house as the blossoms opened, and as the wind was too boisterous to give any but the least air, the fire was allowed to go out during the day, and a broad piece of wood with a handle to it was waved over the trees in sunshine. In quiet weather, when plenty of air could be given, this would be less necessary.

Propagating Beds.—Many inquiries have been made as to the best mode of securing these in small places by means of dry or moist heat, and very minute answers have been given. For small places and especially a living room, nothing can be simpler than a glass-covered case with a double bottom, the upper one of plate iron, or other conducting substance, and a space of 2 or 3 inches between the two bottoms for holding water to be put in hot and partially or wholly removed when cold. After some observation and experience we have come to the conclusion, that as a covering to such upper floor, whether on a large or a small scale, nothing on the whole is better than sand. That will conduct the heat slowly and always be clean, and when once heated it will keep the heat a considerable time. Cocoa-nut refuse, especially when dry, is a first-rate non-conductor. All coverings over a heated bottom diffuse their heat best when the covering is moist. In such a propagating case the atmosphere of the case can always be kept moist enough if the sand on which the pots stand or are plunged in is kept damp. If the atmosphere is apt to become too damp the sand should be allowed to become drier, and more air should be given when there is no sun, as when the sun shines the case must be kept rather close. When the upper floor of such a case is perfectly close—air and watertight—then the owners should recollect that the heat given off will be dry heat, unless modified by a damp covering. Some people talk of the moist heat from hot water; but if the hot water is enclosed in an air-tight vessel from which no moisture can exude, then the heat given off will be just as dry as if it came from a stove or a flue. The heat will be purer, because freer from those exhalations that, if it is not very well attended to, will proceed from a stove or flue, but as respects dryness there will be no difference, as the degree of heat is the same.

In a case with a close upper bottom, or a bed over a tank or chamber similarly closely covered, a moist heat can always be secured by allowing the bottom to be moist; a dry heat by letting it be comparatively dry. Under such circumstances another simple mode may also be adopted. In the close covering have some holes left, to be covered with upright tubes, as small round drain tiles, furnished with plugs at the upper end. These pipes will give a dry heat to the atmosphere of the place when wanted, and wholly or partially opening the plugs will allow moist heat to escape just in the proportion in which it is wanted. Almost all cuttings, except very succulent ones, like a moist atmosphere, as the moisture in the shape of vapour prevents the evaporation of the juices of the cutting—in fact, keeps the cutting from feeling much its severance from the mother plant, by forcing it to absorb, as well as perspire. When the cutting becomes rooted and a plant, there is a danger of its damping-off from an excess of moisture.

When a propagating pit, or case, is heated by a flue, with a rough chamber over it, or the bottom heat is secured by hot-water pipes and a shallow bed of rubble over the pipes, the rubble making a kind of rough chamber, it will often happen that the obtaining suitable heat from these bottom pipes will depend on the air about them not being close or sealed-up, as it were, from the outer air, and also on that air not being

kept dry. An upright pipe at back and front of the pit—say in each light, with its lower end among the lower rubble, and upper end in the atmosphere of the pit, and to be open and shut at pleasure, will, by pouring water down when necessary, always secure bottom heat, and moist heat in the atmosphere of the place when requisite.

Many of our readers, however, will have none of these conveniences, but will want to increase their stock of Pelargoniums, Verbenas, &c., by means of a common dung bed, and to make the most of but little dung too. Where dung and leaves are abundant we need not say anything, as there will be most likely time and opportunity for sweetening it properly before using it, and there will be no difficulty in putting up a sweet bed of from 2 to 3 feet in height, for to do much at this early period the bed ought to be 2 feet in height; and to secure plenty of top heat the frame should be banked round, and if there is not enough of material for that, it should be neatly covered a couple of inches thick with straw tied firmly against the boards.

Where the material is scanty we would not work or sweeten it too much, if there were either tree leaves or the material of an old hotbed to place on the surface, to take the heat from the fresh material, and keep all noxious steam down. This plan is peculiarly applicable to beds for cuttings and seeds sown in pots, as by moving the pots, which will be a work of necessity, we can stir up the bed afresh at any time. Perhaps we shall make the matter plainer by two instances in which specific directions have been required.

A has three small cartloads of stable litter, very strawy and rather dry, and two fair loads of tree leaves collected from different places, a considerable quantity of bits of dry grass along with them, and he wants to know how to make the most of them for his bed as quickly as possible, and with as little reduction of material as possible. Well, then, first pile the tree leaves in a heap, and cover over with a few inches of the long litter, and they will soon heat well. Then take the stable litter and mix it into another heap, making the droppings go as equally through it as possible, and water well as you go, so that every bit of the straw shall be damp. Make the heap tolerably firm, and just cover it with a slight casing of the dry litter. In mild weather this will heat well in a week. In eight days, if the heap is tolerably uniform as to moisture and heat, we would use it directly; if not, we would move the outside covering and turn the heap, moving the top to the bottom and the outsides to the centre, cover again, and leave it for the best part of a week, letting the leaves alone. In either case we would make the bed with as little delay as possible; and as the material is scarce we would merely make the bed a foot or so larger each way than the frame, protecting it and the sides afterwards as adverted to above. Then we would thus proceed: take all the litter from the outside of the dung heap and the outside of the leaves, and with that make the bottom of the bed; then on that build all the dung, shaking it out well but quickly, so as not to let more heat escape than can be prevented; and on that we would place the leaves in a similar manner, keeping them all by themselves, and if some dry ashes or sawdust were placed over them there would be an excellent propagating bed.

B has rather more dung, but has no leaves, yet he has the remains of a summer hotbed, which has a good piece of material about half rotten in the centre, after all the rotten part round the sides has been set apart for growing some fine Celery. In this case, save carefully all the half-rotten material, and after shaking it well pile it into a heap the same as the leaves, and it will heat mildly, and will make a first-rate covering when the dung is used, as in the case of A. When there are two small frames much work may be done with but little material, as then there is no occasion to make the beds large, and the one would succeed the other, and the first could easily be renovated by taking off the surface covering, turning the material below, and adding a barrowload or two to a light, and replacing the surface material again. We often do this with a two-light box, renovating merely one light at a time, and for such beds it is astonishing what a barrowload of fresh warm dung will do when mixed with what was at the bottom before. Nothing more than the leaves would be required for covering, if sure that they were free from slugs and fungus; therefore, a little ashes and powdered lime may be necessary. If sawdust is used, the bottoms of the pots should not stand on it, or in it, for reasons several times given.

We have only room now for a few remarks on sowing seeds and on the management of cuttings.

1. For small seeds sown on the surface, dust with sand, cover the pot with a square of glass, and keep it dark until the seedlings appear.

2. For most seeds, have the pots within 9 to 12 inches of the glass. Every seedling is a perfect plant, and, therefore, should have all the light possible to make it sturdy and strong.

3. To secure economy of management, we prefer now to have cuttings from 15 to 20 inches from the glass. At that distance they will scarcely need shading—a matter of importance, as the more shaded cuttings are, the more they will lengthen upwards without making roots downwards. Diffused light is very different from shaded light. The first will not draw cuttings, the latter will. The first, therefore, until roots are formed will promote robustness, the latter will produce weakness.—R. F.

COVENT GARDEN MARKET.—FEBRUARY 5.

SUPPLIES here have somewhat diminished, and a rather better demand seems springing up. Good English Pears are becoming scarce, and fine French ones command a high price. They comprise *Ester Beaure*, *Beurre de Rance*, and *No Plus Menris*. Forced produce is much improved, and the supply of French salading is excellent.

TRADE CATALOGUES RECEIVED.

Barr & Sugden, 12, King Street, Covent Garden, London, W.C.—*Descriptive Priced List of Choice Seeds for Flower and Kitchen Garden. Illustrated Sheet of Elegancies, with List of Garden Requisites.*

Richard Dean, Ealing, London, W.—*Catalogue of Vegetable, Farm, and Flower Seeds. Catalogue of New and Choice Vegetable and Flower Seeds.*

TO CORRESPONDENTS.

.. We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix upon the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

GARDENERS' EXAMINATIONS (J. G.).—The Royal Horticultural Society have two—viz., one at Midsummer, the other in December. Of the precise dates due notice will be given.

BOOKS (Hortus).—London's "Hortus Britannicus" with its supplements gives the particulars you require, and the "Gardeners' Year Book" publishes annually descriptive lists of the new plants, &c., introduced during the previous year. Appleby's *Orchid Manual* you can have free by post from our office if you enclose thirty-two postage stamps with your address.

(H. C.).—The report can be had, we believe, of Mr. C. Le Fenve, Bookseller, 18, Bedford Street, Jersey. (*Brought up a Ploughboy*). We should advise your not undertaking too much at once, nor studying more than one subject at a time. "The G. der Manual" contains much valuable information on practical gardening, and it may be had free by post from our office for twenty postage stamps. Also the following works, free by post at the prices named: "Out-door Gardening," 1s. 6d.; "In-door Gardening," 1s. 6d. Having mastered these thoroughly you may add "Science and Practice of Gardening," 2s. 10d., which will furnish you with enough of the theory of gardening. The "Cottage Gardeners' Dictionary," contains the popular and scientific names of plants; that you should have, and when you have mastered it, take Thomson's "Gardener's Assistant." But to become thoroughly proficient you will need books treating of particular subjects; for instance, to be well acquainted with fruit nomenclature you must study such works as the "Fruit Manual," and upon any subject respecting which you require very full particulars, works treating solely on the subject must be procured. You will learn enough of botany and chemistry from "Classical Popular Education."

POTATOES ON CLAYEY SOIL (F. Lane).—Ridge the ground; plant on the top of the ridge during dry weather in March. Plant Hogg's Early Goldstream.

HISTORY OF PLANTS (C. W.).—*Allamanda Schottii* was introduced in 1846 by Messrs. Henderson; it is a native of Brazil. *Chelonanthus Thomsonii*, native of West Coast of tropical Africa, sent thence by the Rev. Mr. Thomson to the Edinburgh Botanic Garden in 1861. *Tournefortia spectabilis*, native of Brazil and Peru, introduced in 1829, and in 1841 it bloomed at Chiswick.

CHINESE PRIMROSES (J. E.).—The flowers were all bruised by the post-office punches.

PATENT (*An old Subscriber*).—Messrs. Newton, Patent Office, Chancery Lane, will send you particulars if you write to them. We warn every one against patenting horticultural articles.

SHREWSBURY'S GAS-HEATING APPARATUS (*A Subscriber, Hall*).—Mr. Shrewsbury's advertisement is in this Journal weekly. His direction is "Wholesale Ironmonger, Lower Norwood, Surrey." You had better tell him what sized house you wish to heat. You must have a tube to carry the fumes from the burnt gas into the outer air.

SALT FOR MANURE (E. E.).—If you put 1 lb. on each square yard you would destroy all vegetation; 1 lb. on ten square yards would be quite enough. Apply it, and dig it in a month before you plant your Potatoes.

HYBRIDISING AND CROSSING (G. H. W.).—We know no work specially devoted to this subject. It is noticed at some length in Johnson's "Science and Practice of Gardening."

COTTON (A. B. L.).—It can be grown in our glass structures of a quality as good as that grown in America. Major Trevel Clarke, Welton Place, near Daventry, has had great success in so cultivating it.

GERANIUM CINNABARINA NOT FLOWERING (J. L.).—As your plants grow well up to the blooming state, your treatment is good; all you require is more heat. They should have a light situation and a temperature of 60° at night and of from 70° to 75° by day at this season, but the temperature will, of course, be somewhat higher with sun and air.

RHODODENDRON BED (*Subscriber*).—You may make and plant a bed of *Rhododendrons* at almost any season, as the plants fit with such good balls. We should prefer doing it before the close of April, and as early after February as we could, in order to save watering. A depth of from 15 to 18 inches of soil is ample.

WALL TREES INFESTED WITH INSECTS (*Brought up a Ploughboy*).—You may wash the wall with lime and soft soap, 8 ozs. of the latter being put in every gallon of brine, and dissolved. The brine may be made by dissolving 2 lbs. salt in every gallon of water used. The solution should be applied to the wall as hot as possible, wetting it thoroughly, using a brush as in whitewashing. From your description we should say your trees are infested with scale, to remove which dress the trees now with train oil, being careful to brush it well into every crevice, and not to dislocate the buds, which it is as well not to paint with the oil, unless they are covered with scale. The insects on the points of the shoots, and which make the leaves curl, and these and the fruit sticky and black, are some species of aphids, which may be destroyed by syringing the trees upon a calm evening with tobacco juice diluted with ten times its volume of water, 2 ozs. of soft soap being dissolved in every gallon of the diluted tobacco water. The trees should be thoroughly wetted in every part, and well syringed two evenings afterwards with clear water. The trees ought to be frequently syringed with water during the insect attacks. It may be necessary to repeat the syringing with the tobacco and soft soap solution. We cannot state the cost of dressing a wall and trees with the above.

CENTAUREA CANDIDISSIMA FROM SEED (C. M. C.).—*Centaura argentea* and *C. candidissima* are the same. It is the best white-foliaged bedding plant, and will do well to mix with *Scarlet Pelargoniums*. Plants from seed sown now in a hotbed and kept in heat until May, will, when well hardened-off, be of fine size to plant out in June. The best way of preventing plants damping-off in a heated pit is to take care that there is no leakage or drip from the lights, to give no water beyond what is necessary to keep the plants healthy, and to give abundance of air on all favourable occasions, a gentle fire being employed even in mild periods to dry up damp and promote a circulation of air. You cannot give too much air if you only exclude frost.

KEEPING SCIONS FOR GRAFTING (M. S.).—You may keep them with their ends thrust in clay and half covered with soil in a north border. Grafting wax is better than grafting clay, but the former is much more troublesome and expensive. Grafting clay should have some cow dung mixed with it, which keeps it from cracking.

PLANTS NOT THRIVING (*Subscriber*).—It is very likely you are being giving your plants too much heat. Bedding plants do not require more heat than is necessary to keep out frost; from 49° to 47° from fire heat is quite warm enough. Another essential is air. You cannot afford too much ventilation, only do not give air when the external temperature is at or below 32°. Water but sparingly in winter, no more being given than is sufficient to keep them slowly growing. Perhaps you give little drops and often; that is bad. Let the soil become dry before watering, then give enough to show itself at the drainage, or come through the bottom of the pot; but do not let the plant flag for want of water before

giving any. You may water the plants overhead after this on fine days; but give air, of which we think you do not afford enough, and employ no more fire heat than is necessary to keep out frost and dry up damp. You would have done great wrong to have had a vessel with water upon the fire in winter. The great danger to hedging plants in winter is damp, and you may keep the atmosphere damp enough by sprinkling the floors and walls with water once or twice a-day, which, along with syringing the plants once a-day, will secure sufficient moisture.

EARLY AND SECOND EARLY POTATOES (Bissettan).—Your Holbury Kidneys are no doubt worn out from the continuing to grow them on the same kind of soil for so long a period as a quarter of a century. We should advise a change of sort. Rivers's Royal Ashleaf is an excellent early sort, and Lapstone will suit you as a second early. Your sprouting the early Potatoes is correct. If you have them with sprouts from one-half to three-quarters of an inch long, planting may be deferred until the middle or end of March for the early ones, and the last week in March or first week in April for the second early.

FORMING A QUICKSET HEDGE (Idem).—In order to make a good hedge, close from the bottom, the quicks should be cut down—if strong, the same season as planted; but if planted in autumn it is well not to do so at that time, but in spring. If the quicks are small they should be allowed to grow one year, and then be cut down to within 3 inches of the ground.

PEAT (A Subscriber).—The peat of which you enclosed a sample is too dark and soft for Camellias and Azaleas. Such peat is liable to become a close muddy mass, and is not desirable on that account for plants requiring frequent supplies of water. By adding one-fourth sandstone in pieces from the size of a pea up to that of a walnut, using the fine as well as the rougher particles, you may make the soil more open, which is all you have to do with the compost, and then the peat will answer very well. It should be thoroughly mixed with the soil, and a liberal addition of silver sand ought to be used along with it.

ICE-HOUSE MAKING (Ere).—In No. 318 of THE JOURNAL OF HORTICULTURE, published on the 28th of November, there is a sketch of and full directions for forming a cheap ice house. You can have the number if you enclose four postage stamps with your address.

CHRYSAANTHEMUMS FOR A GREENHOUSE (Idem).—It is not desirable to keep Chrysanthemums from year to year without taking cuttings. They make far too many shoots, and do not grow freely enough to form handsome, well-flowered plants. Fresh cuttings should be put in every year, and the old plants should not be kept beyond the second year without taking cuttings, or putting-off singly the strong suckers; but plants from cuttings are the best.

PLANTS FOR BASKETS IN A GREENHOUSE (Idem).—A dozen good plants for baskets in a greenhouse are: Saxifraga sarmentosa, S. Fortui variegata, Nerveberberia gracilis, Lithospermum fruticosum, Tradescantia zebrina argentea, Lysimachia nummularia, Platycodon alcinone, Adiantum setulosum, Selaginella denticulata, S. coccinea, the Gold and Silver-variegated Ivy-leaved Pelargoniums, and Convolvulus mauritanicus.

BEDDING PLANTS IN A PIT (Man of Kent).—You will be doing well to keep your plants in the pit as cool as you can, taking care to exclude frost. A temperature of from 40° to 45° at night, and of 45° to 50° by day, with air on all favorable occasions, is quite warm enough. Be careful of the watering pot, and do not water oftener than is necessary, as every time you water you must make the pit more or less damp, and that is objectionable at this season. Do not water so long as the plants will continue without flagging; but when the soil becomes very dry give them a good watering, enough to show itself at the drainage. When they commence growing, water should be given more freely, but only when required: the soil should be dry before any is given. The bed for cuttings should be covered with 3 inches of sand or fine soil, and if sand was to be had, a covering 6 inches thick will answer admirably for plunging the pots in. The bed should be covered so as to keep down the rank steam, which will not only injure, but destroy the cuttings. A bottom heat of from 70° to 75°, and a top heat of 65° to 75° are necessary, and the cuttings will bear a higher temperature. The temperature of the bed for the first ten days or a fortnight will range from 70° to 75°, which is not too much. In the day the temperature will, of course, be somewhat higher in consequence of sun heat. The cuttings should be inserted in pots, and the pots plunged in the bed, taking care that it is not so hot as to burn them. The bed will answer for seeds of Stocks, Asters, and half-hardy annuals; but these ought to be sown after the cuttings have struck, as if sown at the same time as the cuttings are put in the frame will be too close for them, and they will become drawn. Whilst the cuttings are striking a little air should be given to prevent an accumulation of damp, otherwise the frame should be kept close and moist, and also shaded from sun, until they have struck. The autumn-struck cuttings will not need to have heat after potting. They should be placed in the pit after potting, and be kept close and shaded for a few days, until they recover. If you can give them gentle heat they will the sooner recover after the potting. In that case they should be well hardened-off and be returned to the pit. Do not keep them in heat.

RAISING VIOLA CORNUTA AND VIOLA LUTEA FROM SEED (Idem).—You may sow the seed of both these very ornamental and neat edging plants early in March in a hotbed, and continue the plants in heat so as to forward them. When large enough to handle they should be pricked-off, about an inch apart, in pots, and be returned to the hotbed, keeping them near the glass, and giving them a moderate amount of air, so as to prevent their becoming drawn. Harden them off well in May. They will be fit to plant out in June, and will bloom in autumn; but for summer-flowering plants from division or cuttings are much better than seedlings, which are not at their best until the second year. They will succeed under the shade of the hedge, but not very close to it, as the soil may in that case be too dry. They require moisture as well as shade—indeed, where the soil is strong and moist, shade is not desirable.

CANNAS (Idem).—The tuberous roots should be potted and placed in a hotbed. You may divide them before potting, and it will be well to have the plants strong and well hardened-off before planting them out, which should not be done before June.

MUSA Coccinea CULTURE (A Dublin Subscriber).—We would advise you to re-pot it, removing most of the old soil, and placing the plant in a pot just sufficiently large to hold the roots without cramping them. The pot should be well drained, and for soil use turf 1½ to 2 inches thick, cut from

a pasture where the soil is a good yellow loam, light rather than heavy. This should be torn in pieces by the hand, and one-third leaf-mould may be mixed with it; likewise one-fourth of dry cow dung, and enough sand to make the compost porous. Plunge the pot in a hotbed of 75° or 80°, keep the atmosphere moist, and maintain a top heat of 60° to 65° at night, and 70° to 75° by day, with an increase of from 10° to 15° on clear days. The plant should have a light situation, and be carefully watered until it is growing freely, when it should be very copiously watered. Weak liquid manure may be given alternately with pure water. Do not water until the soil becomes dry, then give a good supply—enough to come through at the bottom of the pot. When the pot becomes full of roots shift the plant into a larger pot, and continue shifting as the plant increases in size. We would not cut off the stem at the ground, but leave it as it is. If you cut it down, the plant would probably throw up suckers; and if the stem, now 4 feet high, has lost its centre, it will put out suckers. You have been keeping the plant too cool. It is a stove plant, requiring all the light you can give it, and a moderate amount of air. One half the Musas in the country are starved for want of support, and are miserable objects; otherwise they are the most stately and handsome of ornamental-foliaged plants.

PELAGONIUM SEEDLINGS ATTACKED BY INSECTS (Tom Thumb).—We are not aware of any insects such as you describe that eat through the leaves. We should think they are thrips, which will yield to fumigation with tobacco on a calm evening.

CANNAS FOR A SMALL GARDEN (Idem).—Half a dozen with green leaves are—Canna bicolor, C. Sellowii, C. lutea picta, C. Warszewiczii, C. macrophylla, and C. patens Esperen; and of dark-leaved sorts—C. zebrina, C. floribunda, C. rubra perfecta, C. Van Houttei, C. rubriculmis, and C. Warszewiczii Chascl.

APPLYING SOOT (Cornubia).—Soot may be applied with advantage to all descriptions of plants. It may be strewn over ground before digging, be scattered round fruit trees and allowed to wash in, or be spread between the rows of all growing crops, and the stirring of the ground with a hoe will be sufficient working-in. It is best applied in spring. It is an excellent manure for lawns, and should be applied in sufficient quantity to make the surface black. Prior to earthing-up is a good time to apply it. A peck to thirty gallons of water makes a most excellent liquid manure for all growing crops, giving the ground a good soaking once or twice a-week in dry weather.

GAS LIME (Idem).—In preparing ground for fruit trees and vegetables, we should not recommend gas lime unless there was some reason for its application, as the ground being infested with wireworms, and then thirty bushels will be sufficient for an acre. If more be applied the ground will not be fit to plant or sow for six months. We should drain and trench the ground, and if the soil is strong give a dressing of lime at the rate of one hundred bushels per acre, spreading it when fresh slaked and hot over the ground after trenching, and pointing it in with a fork. During dry weather in March is a good time.

MANURE FOR A DRY SOIL (A Reader).—We have had considerable experience of such a soil as yours, light on a gravelly subsoil, and we find the best manure to be cow dung. It is cool and more retentive of moisture than ordinary farmyard or stable dung. You will grow good crops if you enrich the ground well and often, and in dry weather water freely with liquid manure. Do not give a heavy dressing and seldom, but a moderate manuring and with every crop. The most lasting benefit is derived from a good marling, putting on a dressing in autumn so as to cover the ground about an inch thick, and allowing it to become frozen; on a thaw taking place it will fall and may be spread over the ground and dug in. You should plant the Shallots and Garlic during this month, and the earlier the better if the weather be favourable.

PLANTS FOR A VINERY WALL (J. W.).—For planting out—Luculia gratissima, Habrothamnus elegans, Cestrum aurantiacum, Camellia Simbricata, Camellia Monarch, Citrus aurantium (Orange). For pots—Hoya carnosa, Jasminum gracile variegatum, Mandevilla simeolepis, Rhycolispermum jasminoides variegatum, Solysia linearis, and Mutisia decurrens.

POTTING PLANTS IN FRESH LEAF MOULD (J. A.).—Your plants will not suffer from being potted in the fresh leaf mould. It would have been better if the leaf mould had been more decomposed. We would not disturb the plants potted with it. We presume it was thoroughly mixed with the other soil, and in that case you will not have anything to fear from the soil being too open. We think the plants will grow well. Your other plants should have a temperature of 50° at night, be kept nearer the glass, and have a moderate amount of air, being careful not to overwater, although keeping the soil moist. We would not re-pot the Vine, that should have been done in autumn immediately after the leaves had turned yellow. Remove as much of the surface soil as you can without disturbing the roots, and give a top-dressing of an equal quantity of half-inch bones, sheep or horse droppings not very old (three or four months), and turf cut 2 inches thick from an old pasture where the soil is a good rather light loam. The turves may be placed on iron plates over a fire, so as to slightly char them and so destroy the vitality of the grass.

MELONS (Young Gardener).—Three Melons of good size and flavour are Beechwood (Green-fleshed), Malvern Hall (Scarlet-fleshed), and Conqueror of Europe (Green-fleshed).

FRUIT TREES CANKERED (Half-pay).—We should attribute the canker in your fruit trees to the roots being in bad soil. If not old we would recommend their being lifted and planted on the level ground, raising the soil about them in the form of a cone, so as to cover them with 3 inches of soil. The draining of the ground efficiently is your only true remedy.

COPING BOARDS (J. E. B.).—The coping boards are excellent for the protection of the blossoms and young fruit in spring from frost, but they should be removed afterwards, or towards the close of May, as they shut off the rains, and it is not necessary to replace them until the blossoms are expanding. We would not now remove them, but defer it until the end of May. Ammoniacal liquor from the gas works will destroy slugs, and about the trees you name it may be used now with advantage, diluted with six times its bulk of water. A few dressings with fresh lime in the evening after a showery day will soon free a garden of these pests. The best time to apply it is soon after dark, the ground being made white each time.

CENTAUREA RUGOSINA PROPAGATION (D. W.).—The shelf of an early vinery, or the shelf of a Cucumber house heated by hot water, we prefer for cuttings put in now.

POT VINE IN A GROUND VINERY (Rugby).—Your Vine would have done better if planted under your ground vinery in the autumn, and the ground mulched over it. To obtain as much fruit as possible from the Vine this year, we would break holes in the pot, plunge the latter overhead, and place good, fresh, rich soil all round it, to let the roots go out. To do the best for the Vine permanently, but at a loss for this season, turn it out of the pot and spread out the roots. Such a Vine may be raised at the time you name, but we would prefer a young Vine from a cutting now. We would keep the ground vinery over the Vine all the winter.

FORMING A VINE BORDER—VINES FOR A GREENHOUSE (G. W. O.).—You may make the border as wide as the house, or 14 feet, but half the width will do at first if that is an object. With such material, we would to every 2 yards, or two loads of soil, add two bushels of fine rubbish and half a bushel of charcoal and broken bones. In such a house we would plant Vines—namely, 1 Black Hamburgh, 1 Black Muscat of Alexandria, 3 Royal Muscadine, 3 Black Hamburghs, 1 Black Muscat of Alexandria, and 1 Esperione. These will ripen with little fire heat.

DISTANCE OF PLANTS FROM HOT-WATER PIPES (J. D.).—There will be no danger from the hot-water pipes if the shelf is 12 inches from it. Mr. Robert Pettit, of the Botanic Gardens, Bury St. Edmunds, had a fine collection of succulents.

WEIGHT OF A SACK OF POTATOES (J. F.).—In the London markets a sack of Potatoes is required to weigh 168 lbs. Consequently, in answer to your query, it contains 21 stones, of 8 lbs. to the stone.

FLOWER GARDEN PLANTING (Fred).—All we would suggest is more unity and completeness, by edging all your beds instead of part of them. Thus—as 2 is edged with *Lobelia*, we would edge 3 with *Cerastium*, 4 with purple, 5 with lilac, and so on. Without such arrangement there will be a want of completeness.

ARAUCAIA CUNNINGHAMII SINENSIS. —Mr. Thomas Winkworth (see page 91), states that it has withstood the severity of our winters unharmed. He would oblige by stating if it has withstood the severe winters unprotected.—L. X. "Instead of being the tallest of this Conifer at Elmhurst Gardens' is now 6 feet high," as stated at page 91, it should have been "the tallest is now 10 feet high."—THOMAS WINKWORTH.

VINE IN A FERN CASE (K. D.).—It is quite possible to raise the Vine in a Fern case 2 feet high, and 12 or 13 inches wide; but, then, of what use would it be except for foliage? and a more moderate-growing plant would be better. Even for such a case you could not have less than 6 inches of soil—in fact, the Vine would be better kept in a pot. The Royal Muscadine would be as good as any. To do any good with a Vine the case ought to be from 6 to 10 feet in length, and even then we would prefer the Vine to be at one end in a box that would hold at least three-quarters of a bushel of soil, instead of turning it out in the case. Loamy soil is the best.

NAMES OF PLANTS (J. D.).—*Mesembryanthemum gracile* (narrow-leaved); *M. crystallophanes* (broad-leaved). (P. W.).—As the Moss is not in fruit, and I had specimen also, it cannot be named. (W. R. Howell).—1, *Cephalanthus pallens*; 2, *Orchis incarnata*; 3, *O. variegata*; 4, Probably *Orchis latifolia* in a young state.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending February 14th.

DATE.	BAROMETR.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

FOWLS FOR A CLAY SOIL.

I FANCIED Dorkings were not given to eccentricities, but met with a yard where a cock of dark grey colour at his last moult became pure white. However, that is not my theme.

After thirty years' experience—eighteen on gravel, I could tell a sad tale of several years' on a clay soil, where Cochins, Spanish, Dorkings, and Brahmas successively formed a hospital, and yet worse, too often successfully defied the pharmacopœia and every attention. Some Game-looking, badly marked, Golden-spangled Hamburgs, however, turned up, direct from Yorkshire, and a three-years trial has proved them hardy, great foragers, small eaters, non-sitters, and excellent layers even in winter. I believe they are almost identical with those recommended by Mr. Hewitt in his valuable article of April 3rd, 1860, as the produce of a cross between a Game cock and Golden-spangled Hamburgs, or Pheasant fowls; he adds, "The cross with Moonies was not so productive." Now, as Ambition whispers sometimes, Procure a purer stock, which of the five varieties of Spangled Hamburgs—viz., Golden Moonies, Golden Pheasants, Silver Moonies, Silver Pheasants, and Black Pheasants, is the most hardy and productive? I hope this year, by a visit to the north, to be able to speak with authority about these beautiful fowls, too little cultivated in the south of England.

"R. S. S. W.," finds Brahmas perfection; I must disparage them, but I trust in that friendly spirit which has ever distinguished your columns. I admit that strains vary, and mine were hardy, and fair winter layers, but consumed an enormous quantity of food, and in summer the hens were always wanting to sit, and had a remarkable tendency to accumulate internal fat, and produce shell-less eggs.—HENRICUS.

BATH AND WEST OF ENGLAND SOCIETY.

THE usual meeting of the Council of this Society was held on January 28th at Taunton, under the presidency of Sir J. T. B. Duckworth, and was more numerously attended than on any former occasion.

With regard to the Falmouth Meeting of 1868, it was resolved to celebrate the opening of the Exhibition on Monday, June 1st, by a public luncheon in the show yard, in accordance with the practice inaugurated last year at Salisbury with so much satisfaction to

members and the public. For the information of exhibitors, it may be well to state that the Falmouth Local Committee have very handsomely undertaken, at their own cost, to convey all machines, implements, live stock, poultry, and other articles to and from the Falmouth Railway terminus to the show yard free of cost to exhibitors. This concession will go very far towards removing any objection that may exist in the minds of distant exhibitors on the ground of expense.

A letter was read from the Hon. and Rev. S. Best, on behalf of the Southern Counties Association, established several years ago, very much on the model of the Bath and West of England Society, but proposing to direct its efforts more particularly to the six southern counties—viz., Hampshire, Sussex, Berkshire, Oxfordshire, Surrey, and Kent. In this letter overtures of amalgamation between the Bath and West of England Society and the Southern Counties Association were made by Mr. Best on behalf of the latter Society, and a scheme or basis, on which it was thought by them that an amalgamation of the two might be carried out, was stated in detail by that gentleman.

With reference to the overture contained in this letter a long and animated discussion arose. By some it was contended that the Society's area was already sufficiently extensive and ought not to be in any way enlarged; but it was shown by reference to the early records of the Society, that at the annual meeting in 1779 it was resolved that the counties of Berks, Hants, Devon, and Cornwall should be included within the district of the Society's operations; and in December, 1790, a further resolution was passed, that on account of the established character of the Society and the widely extended residence of its subscribers, the title of the Society should become altered from "the Bath Society for the Encouragement of Agriculture, &c.," to "the Bath and West of England Society." Stress was also laid on the fact that the Society in 1856 affirmed the desirability of holding meetings not only in Somerset, Devon, Dorset, Hampshire, and Cornwall, but also in Wiltshire, Gloucestershire, Herefordshire, and South Wales. Eventually a Committee was appointed to confer with a Committee appointed by the Southern Counties Association, and the Secretary was directed to acknowledge with thanks the communication of the Hon. and Rev. S. Best, in regard to the proposed amalgamation, and to inform him that the Council thought it would be impracticable to effect such amalgamation on the basis proposed by him, but they had appointed a Committee to confer with the Committee appointed by the Southern Counties Association.

It was resolved that for the present year only, the Council Meetings held in the months of February, March, and April, shall be held on the last Saturday in the month, instead of the last Tuesday. The day of Meeting in the other months will remain unchanged.

WESTON-SUPER-MARE POULTRY SHOW.

CAN you inform me what the distance is from the railway station to the yard of the late poultry show at Weston-super-

Mare? I sent three pairs of Pigeons in a small box (carriage from London 2s. 6d.). I was awarded the first prize for Dragons (£1), and much to my surprise the Committee in remitting the money deducted no less than 4s. 4d. for railway charges to and from the show yard. I believe it customary on the part of railway companies to deliver goods free of charge on arrival at their stations, provided the distance is inconsiderable, which I believe it to be in this case; at any rate, it appears to me a most exorbitant charge for the company to make, being only 4d. less each way than for the carriage from London.—J. PENCIVALL, Peckham.

PIGEONS' DISEASES.

I AM glad to find that the doubts I expressed as to the diseases of Pigeons being non-infectious have produced another most interesting letter from Mr. Huie. I have several reasons for believing that roup and cancer in the month will spread if not attended to; among them these two:—Early in last summer I purchased all the forward birds of a breeder in this neighbourhood, one of the best of them a Red Pouter hen having the roup badly at the time. This bird I cured, but not before five out of the seven others had taken the complaint more or less severely. The place in which I kept them was particularly dry and warm.

Two years ago nearly half my young birds were attacked with cancer in the month. They were separated entirely from the breeding stock, neither of them at that time being allowed to fly. However, the disease seemed to spread so much that I gave the birds their liberty, which did them a large amount of good, but at the same time I permitted them to perch on and about a wired court to which the old birds have access during the day, and in a very short time afterwards the same complaint appeared in the breeding loft, how or by what means I am at a loss to conjecture, unless it was passed by the young birds to the old ones.

I am surprised at any one considering these diseases to be non-infectious, but should be only too glad to think that such was the case.

Would Mr. Huie say what number of crosses he considers sufficient between two birds, in order that fine healthy Pouters may be produced?—W. R. ROSE, Cranley Hall, Kettering.

DARK AND LIGHT BRAHMAS.

HAVING long taken great interest in both the varieties of Brahmas, I would like to add a few words upon the subject of the alleged monopoly of all the cups by the Dark birds, "what-ever be the merit" of the Light ones; and I must first express my opinion that "our Persian friend" has hit the nail on the head in more respects than one.

I have been, I think I may say, a keen observer of both varieties, and I can unhesitatingly corroborate the assertion of "Y. B. A. Z.," that hardly ever do we see a pen of Light Brahmas that can be at all compared to even a fair average pen of Dark in the real characteristics of the breed. The combs of the Dark birds are often bad enough, but the Light are generally execrable. The legs are clothed with what may be compared to "unmentionables" in more ways than one; the whole "style" of the birds is usually far inferior, and the head has too often nothing of the true Brahma expression about it. This expression is peculiar to the Brahma race alone, and once caught by the eye is never forgotten. It is difficult to describe, but the head of a true-bred Brahma pullet is almost exactly similar in shape, taper, and expression to that of a Grouse, and is one of the best signs of purity of breed. In Light Brahmas, however, scarcely one bird in four possesses it now.

Mr. Pares's celebrated cock I remember well, and I admit that a better Light bird has never been seen of late years; but I have during the last two seasons seen more than a score of Dark cocks quite equal in size, shape, and style, and at least half a dozen more or less superior.

With regard to the causes of this superiority, "Y. B. A. Z." has also stated the truth, but very far from the whole truth. So far as his own opinion goes, I can give a curious corroboration of it. I was in company at Birmingham with one of your correspondents and another well-known Light exhibitor, both noted first-prize winners in their favourite variety, and we were discussing the merits of the first-prize Light Brahma cock. Both breeders complained of the award, although made by Mr. Teebay, and appealed to me if a cock of "such bad colour" ought to have had the cup. Now, the fact was, that

the bird had such a decided grey bottom colour (as a true Brahma should), that having been much knocked about it gave him a decidedly dirty or dull appearance—certainly, I must admit this, though any one could see that in good condition he would be clean enough; but, as to the style of the bird, his carriage, his shape, his tail—it was the old Teebay model come to life again. The bird was really grand, and I could only wonder his splendid proportions should be overlooked by two such noted breeders.

I have remarked that "Y. B. A. Z." has stated very far short of the whole truth in this matter, and I think I can point out the chief reason of the deterioration he alludes to, and which no amount of legitimate breeding for colour can fully account for, though in part it may.

I have still in my possession somewhere a letter addressed to me by a celebrated exhibitor of both Dark and Light Brahmas, who has taken many a "first" at Birmingham and elsewhere, but whom, as the letter was in confidence, I cannot of course name, expressing his opinion that the Dark is the original and true Brahma, and that the Light variety was produced from it by crossing with the White Cochins. With this opinion of his I have, of course, nothing to do, save to say that it is quite untenable; but the essential point is the fact which the writer proceeded to state, that a large proportion of his own Light birds, which had won numerous prizes, were thus bred between a Dark Brahma cock and White Cochins. Now, it is not necessary to suppose that all or most Light breeders adopt such a plan to account for a cross of this kind causing general deterioration. Birds from any noted breeder are continually being purchased, and thus the taint is carried into other yards and indefinitely propagated. The result is what we see.

The evidence, apart from the letter I refer to, is undeniable to any who understand the Brahma fowl in its proper characteristics. The head I have already alluded to. The comb is another point equally conclusive. Very few Dark strains now, if pea-combed, ever throw a single-combed bird; but in Light, if you pick your stock from any yard, and choose the very best birds, you will have a large proportion of single-combed chickens, showing a tendency to revert to the Cochins type. The narrow deficient breast is a third proof, and occurs in half the pens now seen. And not to mention more minute characteristics obvious to keen inspection, I will adduce lastly the under colour of the plumage. In nearly half the Light Brahmas as now shown the colour is white down to the skin; whilst I have the fullest conviction that no pure Brahma, of any colour, was ever bred that had not a grey bottom colour, whatever the surface might be. To sum up all, I have seen scores of so-called Light Brahma hens, which, except for their black-tipped tails, could in no possible way be distinguished from inferior or degenerate White Cochins.

As to the relative merits, *per se*, of Dark and Light I shall say nothing. The Dark will always be more kept on account of their looking so much cleaner in confinement, but no one can be blind to the exquisite beauty of a really good and pure-bred Light bird. Were I judging a mixed class I should place the birds with regard simply to their merits as Brahmas, weighing well the shape, the size, the build, the comb, &c. These being equal, the cup should go to the pen most perfect in colour according to its own standard; but I can never agree to a cup going to pens, however snowy white, if so weedy, narrow-breasted, bad-combed, and Cochins-crossed, as generally meet the eye. The remedy is in your correspondents' own hands. Let them breed again for size, shape, comb, and feather, and, above all, shun a Cochins cross or taint as they would the plague. I have seen recently a hen belonging to one of the complainants, said to weigh 12 lbs., and she looked it. Her shape, comb, and colour could hardly be surpassed, while her leg-feathering was good, and she had the genuine head—rarest of all. I venture to assure her fortunate owner, that if he will perpetuate that kind of bird, or if he can obtain a cock worthy to go with her, he will not long be "left out in the cold."

While I thus contend, however, that the Dark birds are generally far superior in size to the Light, it is worthy of remark that white birds always look small in comparison with darker; and this fact must be kept in mind by judges in estimating size.—NEMO.

I HAVE been much gratified at the able way in which the claims of the Light Brahmas to equality with the Dark have been vindicated in your Journal during the last few weeks by Mr. Worthington, Mr. Pares, and others.

The growing popularity of the Light birds, and the increasing numbers exhibited at all shows where there is a separate class for them, would, I feel sure, make it highly remunerative to secretaries of shows to insist upon that equality whenever the two classes are competing for the same cup. They would immediately gain a great increase of entries, as Light Brahma breeders will not exhibit their birds in a mixed class as long as it is a notorious fact that these cannot be first, however excellent they may be.

"At the great majority of shows Brahmas have been divided into Light and Dark," as "Y. B. A. Z." writes in your Journal this week. Such, no doubt, is the case; and encouraged by the concessions already made, Light Brahma breeders wish still further to establish the claims of their birds. Dark Brahma breeders are not likely to be dissatisfied when they are always at the top of the tree. Light Brahma breeders will not be dissatisfied when the just merits of their birds are allowed.

"Y. B. A. Z." writes, "Wherever he goes he is struck with the degeneration of the Light birds." Can he have been at the late Birmingham Show? and can he make this assertion after having inspected the fifty-eight pens of Light Brahmas there exhibited?

I trust that there are palmier days in store for the Light birds than any that have gone before, and I do not see why the death of one "old cock," however beautiful he may have been, should daunt the efforts of the Light Brahma breeders.—BENGAL.

[We have several other communications on the same subject, but we can only insert them by degrees.—Eds.]

MEALY POUTERS—MATCHING FOR COLOUR, &c.

The correspondence in your columns respecting Mealy Pouters and their use as crosses appears to be proceeding on a wrong basis to some extent. The question for the breeders of to-day is not so much what may be done in crossing, but what really should be done under the present aspect and condition of Pouters as a class.

I have not had the pleasure of reading Mr. Tegetmeier's work on Pigeons, and therefore approach this subject wholly irrespective of his book or its reviews; but I have had the great advantage of a long practical experience with this class of birds, and for the last two seasons have very carefully studied the great annual Show at Glasgow, the stronghold of the Pouter fancy. On each of these occasions upwards of three hundred Pouters, contributed by the most experienced breeders, were exhibited, and my observation of these birds has led me irresistibly to the conclusion that, in order to obtain great size, vigour, style, and length of feather, a most deplorable deterioration of colour and marking has been permitted; and that, if a radical change in the system of matching be not shortly accomplished, the English Pouter will soon be the worst-plumaged bird of all the Pigeon varieties. Almost any kind of matching promising good results on the side of size, vigour, &c., has been the fashion: hence a very free, not to say reckless, use has been made of Mealies, Chequers, Splashes, and pale birds, for these are commonly to be found of great size and handsome proportions; while colour has become impoverished, the marking more and more wildly inaccurate, and the limb in many instances far too short for the increased length of feather.

Now, what is the remedy for this state of things? and as "colour" is the main feature of this useful discussion, how are we to obtain Blacks of raven brilliancy, Reds rich and lustrous, Blues pure and untainted with chequer, and with bars free from kite marking? Surely by importing into the department of colour those processes of "selection" and mating which have proved so effectual in the domains of size, contour, and vigour; and just as birds have been selected and mated for the production of the one set of properties, must they now be selected and mated for the other, and indeed for any property that may require attention.

While fully valuing advantages already gained, future progress demands that birds of defective plumage should be for a time rigorously discarded; that the soundest colour obtainable should be exclusively used for breeding and crossing; and that the utmost circumspection must be exercised to avoid dilution, or any confusion calculated to impair the colour in richness, smoothness, or lustre.

The revival, purification, and establishment of the standard colours will be a prelude to many interesting experiments and crosses at present wholly impracticable in the very impure

state of the useful strains; and in this revival the Mealy is destined to play but a very subordinate part. His work has been done, and for a while he must be mainly conspicuous by absence. Nevertheless, the object proposed can be accomplished without impairing the Pouter in constitution, size, or symmetry; for in every colour there are many families of grand birds sufficiently unrelated to supply crosses for some time to come, so that little or no plea remains for the continued and direct infusion of doubtful elements, especially as every strain is completely saturated already with Mealy and Chequer blood.

Size and strength exist in profusion, our lofts teem with birds of unsurpassable vigour; it only remains now for the sound fancier to maintain advantages already acquired, and to superadd these properties hitherto neglected and deficient, bearing in mind that his real triumph can never be in one-sided excellence, but in accumulating in one specimen as many or all of those properties which give charm and character to the English Pouter.—W. VOLCKMAN, *London*.

PIGEONS, THEIR COLOURS AND DISEASES.

I CANNOT refrain from adding my meed of praise to Mr. Huie for his able article on Mr. W. B. Tegetmeier's work on the domestic Pigeon.

I think it would add considerably to the benefits conferred by your Journal, if some of our most experienced fanciers would insert an article occasionally on matching, breeding, and rearing the high class fancy Pigeons, their diseases, cures, &c. This would be a great boon to amateurs, and fill a want that has been long felt by young fanciers, seeing we cannot supply it by any of the latest productions published.

I quite coincide with the remarks Mr. Huie made in your Journal of the 16th ult. I purchased a bird on the Continent in August last. On its arrival here I found it suffering from roup; I kept it confined in a cage for six weeks, giving it roup pills, and washing its mouth and nostrils with alum water. I found it made little progress. I caught hold of it and threw it into the loft where upwards of fifty more birds were. It has remained with them up to the present time, taking its food from the same hopper, and drinking from the same fountain as the others, and am glad to say not one bird has caught the disease.

With regard to matching for colour, it is certain, and must be patent to the most obtuse observer, that on matching Yellow or Red, and Mealy together, it is a thousand to one but the produce will be worthless mongrels as far as colour is concerned, while by proper selection of colours you can in every instance depend on obtaining good colour, whatever the colour of the progeny may be. I have seen, I may say, all the best birds in Great Britain, and venture to say I never saw twenty good-coloured Reds and Yellows in the whole collection, which must account for so many bad-coloured birds, if the system in question be persevered in by some of our largest breeders.—A. H. STEWART, 4, *Anderton Street, Birmingham*.

[Our columns are open to Pigeon fanciers, and we will readily insert their communications, for we wish to make this Journal their organ for obtaining and imparting information.—Eds.]

UTILISING AND UNITING CONDEMNED BEES.

(Continued from page 106.)

OPEN driving is somewhat slower in its operation, as the bees can ascend only from one side of the hive; but it is by far the most convenient when it is deemed either advisable or essential to secure the queen. In this case it will be well for the beginner, before commencing operations, to pass the threaded packing-needle just through the crown of the empty hive from the inside, leaving the string hanging. Then commence as before by blowing a few whiffs of smoke into the inhabited hive, invert it on the bucket, put the bee-cloth and decoy hive in their place on the floor-board, cover the inverted hive with the one in which the packing-needle has been inserted, and stand the whole on one of the chairs in some shady spot. Having ascertained in which direction the combs run, stick the skewer into the edge of the lower hive opposite that end of the centre comb towards which the bees appear most to congregate, and turn this part away from the operator, who, with the left hand supporting one side of the empty hive, keeps it upraised in such a manner as to afford a clear view of the interior, and raps away with his right, whilst his gaze is intently fixed on the point of junction between the two hives,

where the bees will soon begin to ascend, and which it is certain the queen must pass. If, as is very generally the case, a number of bees gradually form a thick cluster at this point, under cover of which the queen may, perchance, slip past unperceived, the upper hive should be lifted and so far turned round as again to present a clear surface, which her majesty will scarcely be able to traverse without being perceived. And here, probably, many will be inclined to ask if the queen is not invariably amongst the foremost, since we are told in bee-books that she is always one of the first to ascend, and it is a popular idea that the queen leads the workers on these and similar occasions. All this is, however, a mistake; the queen may make her appearance at any moment, sometimes with the vanguard, oftener amongst the main body; sometimes with the rear-guard, and occasionally, although very rarely, she lingers among the last few stragglers remaining in the hive. As soon, however, as she is perceived she should be adroitly seized by the wings, popped into one of the little perforated boxes,* which is then tied to the loose end of the string, and by means of the packing-needle drawn up to and secured in close contact with the inside of the crown of the upper hive.

The desired object having been attained, the operation may be brought to an end as rapidly as possible, either by close or open driving, and the deserted hive conveyed in-doors. Should the queen escape detection, and it be merely intended to drive the inhabitants of two hives into one with the view of establishing them as a new colony, the same look-out may be kept for the second queen, whilst the bees are being driven in a similar manner into the same hive. If, however, she also escape, it is probable that no great harm will have been done, since bees generally dispose of a superfluous queen under such circumstances without much loss of life. There are, however, exceptions even to this rule, and sometimes both queens are sacrificed. It is precisely to guard against such casualties that I always take the trouble of at least endeavouring to secure the first queen in the manner I have described, and when I miss her (which, however, occurs only in a minority of cases), I do not drive a second colony into that hive, but reserve it for a purpose which I shall afterwards describe. I have stated that a veil or bee-dress is but seldom used, and however extraordinary it may appear to many, it is, nevertheless, a fact that an adept will prefer to practise even open driving with exposed face and unencumbered hands, whilst it is equally true that he but rarely receives a sting. I do not, however, commend this example as one to be immediately emulated by the beginner, who should not disdain the protection of a veil and india-rubber gloves, unless he happens to be constitutionally impervious to the effects of bee stings.

When the inhabitants of two hives are driven into one, it is better, as soon as the operation is completed, to confine the bees by standing the hive containing them on the floor-board of the strongest of the two stocks, and tying them up in the cloth with which it is covered, without regard to the stragglers from the other colony, which are not likely to be very numerous. It is, in point of fact, advisable to adopt this course in all cases if the operator intends to quit the scene of action before nightfall, as the bees will congregate more completely within their new dwelling a few minutes after it has been placed on the old stance than they are likely to do until darkness begins to close in. The safe custody of the bees should be farther insured by a string or small cord tied tightly around each hive and outside the cloth between 1 and 2 inches from the bottom, whilst ventilation should be cared for by standing the hives on an uneven surface, or raising one side an inch or two by means of a stone or block of wood.—A DEVONSHIRE BEE-KEEPER.

(To be continued.)

FISH FAILING IN AN AQUARIUM.

STAUNCHING A CANARY'S BLEEDING.

I HAVE a large aquarium with an almost constant fresh supply of water flowing into it. It contains about ten gallons of water, and I am unable to keep fish of any kind alive in it beyond two or three weeks. Its contents are a brass lacquered tube for the pipe, shingle, washed sand, and the following plants—*Potamogeton oblongum*, *P. gramineum*, *Ranunculus aquatilis*, *Vallisneria*. The fish almost at once become affected with some fungoid growth, and seem to shrink and wither. They are fed occasionally with the small red worm, but soon die. Is

* As the object of imprisoning the queen is generally to keep her alive for a few days in case of accident, it is desirable that a few workers should share her captivity.

this explained by any improper plant, or is the brass tube the cause of my trouble?

I will mention one other subject before I close. I called in a noted bird fancier to cure a deformity in the leg of my Canary. His remedy was to amputate with a pair of scissors close to the joint. Considerable bleeding followed, and he suggested a hot wire, but this I considered adding one barbarity to another, and instead I applied the perchloride of iron, which immediately arrested the hemorrhage. Therefore I recommend it with full confidence as being a potent application in case of injury to the combs of fowls by operation or accident, and one free from pain.—WM. SOPER.

[We know a similar sized aquarium similarly managed, and in the water of which similar plants vegetate, and in that aquarium Gold and other fish, small tortoises, &c., are long-lived. Is there not something deleterious in the water you employ for the aquarium?]

FEEDING BEES.

PLEASE to inform me if I had better feed my bees now (January 25th), or what I had better do. No. 1 weighs, exclusive of hive, 17 lbs.; No. 2, 19 lbs.; No. 3, 11 lbs.; No. 4, 18 lbs.—G. J.

[We should consider the stocks amply provided with food, with the exception, perhaps, of No. 3, which, however, will doubtless do well enough until the latter end of next month, when spring feeding may commence and the deficiency he made good.]

OUR LETTER BOX.

POLISH FOWLS' EGGS (*St. Edmunds*).—We recommend you to consult our advertising columns, and to write to any one of the advertisers who has taken prizes with birds of the variety you require.

HOUANS (*Jemima*).—Write to Mr. Baily, 113, Mount Street, Grosvenor Square, (A. P. C.).—We think you may safely keep Houans if your wall is 5 feet high. We do not find them disposed to stray or to fly.

SPANISH PULLETS' COMB DRYING-UP (—).—Your Spanish pullet is failing in condition. Nothing is more certain evidence of it than the drying-up of the comb; but judging from what you say, we should look for a quick return to health. If she has not a grass run, she should be well supplied with sods of growing grass, with lettuce if to be had, and with cooked meat chopped fine.

DUBBING A GAME BANTAM COCKEREL (*H.*).—The skin under the throat should not be touched at all. The comb, gills, and deaf ears must all be taken off closely—as closely as possible, but the skull must not be laid bare. The gills must be taken off so that when the wound is healed there is nothing to show where they were. They should be cut off the skin under the throat.

DORRING COCK (*J. H. J. S.*).—The bird requires no other treatment than that you are giving him. We do not for a moment believe he is otherwise than a useful bird. Such complaints are common at this time of year, but a little patience proves them to be groundless.

KEEPING POULTRY FOR EXHIBITION (*Maggie*).—If you want to breed prize poultry you must have a larger space for rearing chickens than that you name. You have room for the parents, and sufficient to breed anything of perfect quality; but the chickens want more space than 20 feet square. You may rear good useful birds, but we fear there would be no prizetakers among them. Your other arrangements are good. You will find the knowledge you require in any of the poultry books. Be careful by some means or other to provide your fowls with growing grass.

AMOUNT OF FOOD FOR FOWLS AND DUCKS (*Constant Reader*).—We cannot say what amount of food your Ducks and fowls require, because we do not know how much they find in the farmyard—for instance, whether threshing is always going on, whether hogs are being fed—in fact, whether food is to be had for the looking-for. Ducks do well on oats. The fowls will want barley. Their appetite must guide you as to quantity. As a rule they require more in winter, and less as the weather improves in temperature, and the nights become shorter.

SCURF ON LEGS OF WHITE COCHIN-CHINAS (*Surrey*).—The scurf of which you complain is caused by the action of snow on the legs. It will soon disappear from the legs of the pullets; it will remain much longer on the legs of the hens. In some cases it becomes chronic. Time will cure it, but stimulating ointment accelerates recovery.

OLDHAM SHOW.—In last week's Journal the Messrs. Newbitt are represented to have taken the third prize in Any other variety of Ducks. My Buenos Ayrean Ducks were by mistake penned in their pen, which should have been empty, as they did not send the Ducks they had entered. Mr. Charlesworth's pen of Brown Call Ducks were by mistake put into my pen. They were highly commended, and mine took the third prize.—SAMUEL BURN, *Whitby*.

CHINCHILLA RABBIT SKINS (*W. L.*).—We do not know the present price of Chinchilla Rabbit skins. They are articles of export, and vary in price.

LIGURIAN BEES (*Novice*).—We do not know any one on the Continent to whom you could apply. Advertise for the information.

DEAD BEES TROWN OUT OF A HIVE (*A Subscriber*).—The mortality, about two hundred, is rather large, but so far does not appear to be serious. We presume your bees do not want for food, but a few ounces of diluted honey or simple syrup presented to them in an inverted bottle on fine and mild days may be of service, and can in any case do no harm.

BAR-FRAME HIVES—CENTRIFUGAL MACHINE (*A Lover of Bees*).—We believe the only English patent ever granted for bar-frame hives was obtained by Major Munn. We do not know the date of this patent, but have little doubt that it expired long ago. Mr. Woodbury promises a description of the German centrifugal machine. If you write direct to him at Mount Radford, Exeter, he will furnish the required particulars as to price, &c. We readily answer all queries on apianian subjects, and record all that is new.

WEEKLY CALENDAR.

From observations taken near London during the last forty-one years, the average day temperature of the week is 45.3°; and its night temperature 30.5°. The greatest heat was 59°, on the 16th, 1867; and the lowest cold 0°, on the 13th, 1855. The greatest fall of rain was 0.50 inch.

NOTES ON LILIUMS.

SELDOM seeing in the Journal any remarks relating to Lilies, I fancy they do not receive the attention to which they are entitled by their great beauty and variety. I am aware that since the introduction of *Lilium auratum* there has been a "run" on it, and it has been considered "the thing" to grow it; but still I do not think that it has induced many persons to cultivate the other species. I am foolish enough to still prefer the varieties of the old *Lilium speciosum* to *Lilium auratum*. I am aware that when the flower of *auratum* first opens it is wondrously beautiful and grand, but on the second day it loses its freshness, and by the third its colours are dull, and all its beauty gone. *Speciosum* varieties, on the contrary, increase in beauty and brilliancy for several days. Do not imagine that I underrate *auratum*, I admire it much, and am growing some two hundred bulbs of it, and I feel great pleasure in comparing and noting its numerous varieties, although I have not as yet been so fortunate as to find any red-banded or spotless ones amongst my numerous family. I have been crossing my *Auratum*s and *Speciosum*s, and also some of the rare and little known but very beautiful varieties of the Lily tribe, and I have now a large lot of juveniles, but it will be many years before I can know to what extent I have been successful in producing beautiful hybrids.

I grow all my Lilies in pots, and during the last season I took notes of the best varieties. In the winter I have a "second summer" among my flowers by looking over these notes as I sit by my fireside. I place a few extracts at your disposal, but fear that your readers will see nothing but "dry bones" where I find continual enjoyment in mentally filling up the bare records of dead beauties. I have procured my varieties of *Speciosum* from various sources, and find that they vary very much. Some under the same name would be very fine from one grower, and from another utterly worthless. I have, therefore, given the name of the vendors in each case.

Lilium speciosum Schrymkei (C. Verdier).—Petals very broad. Flowers very large, and of perfect form; dark ground, and very dark spots. Fine habit. Very splendid, the finest of this species.

L. speciosum Harrisoni (Harrison).—Very broad petals. Flower of fine form, flesh-coloured ground, with bright spots. Good habit, but the foliage inclined to curl. The largest flower of this species. Very fine.

L. speciosum atro-purpureum (Laurentius).—Broad petals. Moderate-sized flower, of fine shape; dark rose ground, with dull crimson spots. Splendid habit. Very fine.

L. speciosum album praeox (Laurentius).—Petals broad. Flower large, and of perfect shape. Splendid habit. Very much earlier than the old *album*, free flowering, and very fine.

L. speciosum Flora (Laurentius).—Broad petals. Flower medium-sized, and of fine form; bright ground, with crimson spots. Fine dwarf habit, free flowering. Very fine.

L. speciosum album (E. Verdier).—Very broad petals. Flower very large, and of very fine shape; pure colour. Fair habit. Fine.

L. speciosum corymbiflorum rubrum (Veitch & Sons).—Petals broad. Flowers large, and of fine form; bright rose ground, with dark rose spots. Habit good. Fine.

L. speciosum cruentum (E. G. Henderson).—Long narrow petals, very much reflexed. Flower medium-sized, and of good shape; cream ground flushed with rose, plum-coloured spots. Very distinct and good. Bad habit.

L. speciosum rubrum punctatum (Laurentius).—Broad petals. Flower small, and very much reflexed; pure white ground, dull flesh-coloured spots. Splendid dwarf habit. Very distinct and good.

L. speciosum atro-rubrum (Wheeler).—Petals broad. Flower of medium size and fine form; dark ground and spots. Very good.

L. speciosum atro-sanguineum (Wheeler).—Medium petals. Small flower of good shape; beautiful dark ground and spots. Very fine.

L. speciosum roseum delicatum (E. G. Henderson).—Petals very broad. Flower large, and of fine shape; French-white ground flushed with light rose, dark rose spots. Fair habit. Distinct and fine.

L. speciosum purpureum (Laurentius).—Medium petals, and medium-sized flower of very fine form; rose ground, much deeper in the middle of each petal, forming quite a dark band; also much darker and brighter just beyond the point of the nectary; extremely dark spots. Fine dwarf habit. Very distinct and splendid.

L. speciosum rubrum (E. Verdier).—Petals very broad. Flowers large, and fine form; flesh-coloured ground, with large purple-crimson spots. Good habit. Fine.

L. speciosum roseum (Hooper & Co.).—Very broad petals. Flower large, and of fine shape; ground almost white, with purple-rose spots. Good habit. Fine.

L. speciosum Vestalis (Wheeler).—Medium petals. Medium flower of very fine form; colour dead white. Foliage very dark green. Habit fine. This very distinct and beautiful variety was raised by Mr. Wheeler, of Warminster.

L. speciosum rubrum (Laurentius).—Very broad petals. Flower large, and of fine shape; mottled rose ground, with bright crimson spots. Fine habit.

L. speciosum Hendersoni (?) (E. G. Henderson).—Broad petals. Large flower of perfect form; purple rose ground, with dark, rich, crimson spots. Distinct foliage, and good habit. Splendid. This was obtained as *Harrisoni*, but is very different from that variety.

L. speciosum regale (E. G. Henderson).—Beautifully formed flower of medium size; ground and spots very dark. Very bright and beautiful. Good habit.

L. speciosum monstrosum (?) *roseum* (Barnaart).—Broad petals. Medium-sized flower of good shape; pale flesh-coloured ground, bright rose spots. Good habit.

All the twenty I have mentioned I consider fine, and they are mostly distinct, and some of them are very lovely. The following are good, but not up to the standard of the first lot:—

L. speciosum punctatum (E. G. Henderson).—Large and

well-formed flower of very delicate colours, but rather dull-looking. Habit bad, and a shy bloomer.

L. speciosum corymbiflorum punctatum (Laurentius).—This is one of the monstrous varieties, with the flowers all in a heap, a style which I do not admire, but the freshness and delicacy of colour in this flower induce me to tolerate the hideous stem. — *L. speciosum macranthum* (Laurentius).—Good, large, dark flower, but dull in colour.

L. speciosum compactum (E. G. Henderson).—Flower small, very dark, but dull-looking. Very dwarf habit. Erect flowering. Shy bloomer.

L. speciosum rubrum Extra (Van Geert).—Good-shaped medium-sized flower; ground flushed with rose, dark spots.

L. speciosum album (Van Geert).—Medium-sized flower of good shape; beautiful, pure colour. Fine habit; the bud not liable to twist as in the old album. It is also much earlier than that variety.

There appears to be great confusion in the trade respecting the varieties of *Lilium speciosum*, and when you order from any list it is very uncertain what sorts you will obtain. There are so many different strains of *Lilium speciosum album*, *roseum*, *rubrum*, and some others, that it appears to be quite impossible to keep them distinct.

Although there are many other species to dilate upon, I must conclude this paper, hoping that some other Lily-grower will give us the benefit of his experience, and let us know what choice varieties he has the happiness to own. Perhaps some raiser of seedlings will tell us the results of his labours, and describe the beautiful "bairns" he is the father of, and how many years passed before they showed him their lovely faces.—*HEPHERUS*.

SOILS AND SITUATIONS FOR CONIFERS.

NOTWITHSTANDING all that has been written on Conifers, the question is still often asked, What position should this or that Conifer occupy? Failing to secure correct data to guide us in these matters, except the teaching of Nature, which all of us have not the opportunity of obtaining, perhaps the nearest approach to it would be a statement of the experience and observations of your readers, the particulars of which could be condensed into tables, and, perhaps, the various subjects could be arranged in classes, having regard to situation, soil, &c. An arrangement of this sort would do good service—it would prevent much disappointment, and be far more valuable in my opinion to future planters than details of the effects of frost without such particulars, because in many instances it is more than probable that the soil has caused the mischief and not the frost, and that the position is at fault when trees are blown down, and not the wind. I believe it is often the case that the very preparation of the soil for planting some of the best Conifers is only laying the foundation for their death; not because they refuse to grow in the soil, but because they are forced to an excessive growth.

The havoc made by frost in the case of *Pinus insignis* is in many instances attributable to the soil it is planted in; in short, the soil is too fertile, and, like an overfed child, the tree succumbs to the first attack of cold.

I have seen pits dug deep and broad, and filled with rich compost for this tree. I question if this practice would answer even where the temperature is never below the freezing point. What is the consequence? Long shoots, which before they are properly hardened start into growth again, and before this growth is completed grim winter is upon them. What chance has a tree in such a state to pass through a severe winter?

Again, I have seen this tree treated in a way quite opposite—i.e., having no preparation of soil beyond the breaking-up of the natural one, which was stony and poor. The tree made short shoots yearly, but became thoroughly hardened, and seemed to stand cold or wind as well as *P. austriaca*. Here was an exemplification of consulting Nature, while the other case was an unwise interference with her laws. If a tree is adapted by Nature to grow on rocks and between rocks, adapted to entwine its roots around stones and bore deep down after moisture, why should it be placed in a moist soil prepared with high-feeding ingredients?

The Pinuses, as a class, ought to occupy an elevated position on stony ground, and if it is found necessary that they should be fed, let it be done by mulchings on the surface. The Spruce family, according to my observation, will do best in lower positions; indeed, the best plantation of Spruce I ever saw was in wet clay with a fall sufficient to carry away the water,

which ran out of it through the winter. The trees will take a firm hold in deep soil though it be poor, so long as it is damp; while Larch, for instance, although it seems to penetrate a rock in some situations, will not go through wet clay. I have known the Larch grow to a good size and be at last blown down because it had no hold in the soil, none of its roots being found more than a foot beneath the surface in such situations.

The Arbor Vitæ and Junipers will succeed in low places where the soil is rather damp, better than in high dry places. I am speaking of the natural soil. There is still some doubt as to where the *Taxodium sempervirens* should be planted. Much has been said against low damp situations for planting this tree, and that it will not thrive there. Now, my experience and observation are opposed to this assertion; provided the tree is not overfed with rich matter in the soil, I believe it would even grow in a bog. The first tree I ever saw, which is nearly twenty years since, was planted very near a piece of ornamental water, and it did so well that I have always thought it out of place in any other but low damp situations. Its rusty appearance in elevated positions tends to confirm this view. I have seen it since in similar damp positions doing equally well, and I could point out some trees growing so near the water that many of the roots must be under water all the year round. It is in company with the *Osmunda regalis*, a Fern which delights in moisture. That circumstance alone would at once give sufficient evidence of the nature of the situation; but there is more clay here than is commonly found where this Fern abounds. The appearance of the tree just alluded to is everything one can desire, not in the least drawn-up, but short-jointed and dense, with a dark green colour seldom seen in trees in higher positions. I shall, therefore, put this tree in the class for damp situations.

The east wind is a great enemy to *Taxodium sempervirens*. Having several trees under my daily notice in almost all kinds of situations, I find those exposed to that wind are always brown on the east side, and one-sided besides. The east wind seems to singe the young shoots as they appear, and the trees are miserable, irregular subjects destitute of beauty. Others in a moderately dry soil, although they always look brown in spring, do grow a little every year, but are very poor trees compared with those planted in moist situations. One feature I have noticed in trees in high dry situations, not open to east winds, which I have not seen in those in lower places—is that they blossom; and I have picked a few cones from them, but the seed has not grown. This *Taxodium* is a beautiful tree when well grown, and the timber, I am told, is also valuable; it ought, therefore, to be extensively planted.

I have not had the opportunity of testing the *Wellingtonia gigantea* in wet places, but the tree being from the same locality and so much resembling the *Taxodium* in some respects, I have no doubt it will do in moist situations.

I have found the Cedars do best on high stony ground, while the *Cryptomeria japonica* will grow in a very wet soil. I have seen some trees so near the water that unless the *Cryptomeria* was fond of moisture the roots must have rotted, but this has not been the case, the top of the tree having every appearance of health. Not far from the *Taxodium* alluded to above as being near the water, there are some *Cryptomerias* growing in a manner I have never seen in trees planted in high positions. In colour and character the trees are so different from many growing in similar positions, that one might be excused for taking them to be another variety. Some Cypressess are also flourishing in the same soil. A Silver Fir which is, I should imagine, a self-sown one, is growing in an island in the middle of the water; although it is no better than many others, yet it is a proof it will stand wet soil.

I might enlarge these notes by citing instances which tend to prove that many of the Conifers will not only do well in damp places, but there succeed the best; but my object when commencing writing was to condemn high cultivation, or over-feeding of Conifers, which is often the cause of failure where the trees are in low places, and not the situation. If this matter be attended to, and care be taken to give room, air, light, and as much sun as possible to the top of the tree, there will be less complaints respecting the failure of Conifers.—*H. MILLS, Enys, Penrhyn.*

CATERPILLARS ON BEDDING AND OTHER SOFTWOODED PLANTS.—My bedding and other softwooded plants having been seriously injured by caterpillars, I was induced to feed up several specimens, and found them to be the caterpillar of a moth

which I have no doubt is the cabbage moth (*Mamestra brassicae*), very destructive and common everywhere. The perfect insect appears in May and June.—FRANK FOWLER, *Ravenstale Park Gardens, Newry, Ireland.*

POTATO PRODUCE.

THE extract which you gave from the Journal of the Royal Agricultural Society on Potato produce was exceedingly interesting. The experiments having been conducted on so large a scale, and with the great care and attention which Mr. May bestowed upon them, are, doubtless, entitled to great weight and consideration, and are very important. Very possibly I am wrong; but, still, the deductions derived from the result of his experiments are, to my mind, somewhat contradictory, and it would be a great boon to Potato-growers in general if some of your correspondents would be good enough to give us their experience, or the result of any experiments they may have made in the culture of the Potato. I cannot help thinking that it would have been useful if Mr. May had enumerated the varieties experimented with, the nature of his soil, the quantity and nature of the manure used, and whether the plants were earthed-up or not.

I cannot quite reconcile in Mr. May's *résumé* of the results the following deductions:—

1.—“Every increase in the size of the set, from 1 oz. to 8 ozs., produces an increase in the crop much greater than the additional weight of the set planted.” 5.—“That the weight of the crop is proportionate to the weight per acre of the sets, and that small sets will produce the same crop as an equal weight per acre of large sets.” The remainder of the deduction as to the fact being of limited application, is, of course, indisputable. 7.—“That smaller sets give a larger produce in proportion to their weight than the larger sets.”

Deductions 1 and 5 do not, according to my interpretation of the experiments, coincide with 7; for it would appear that if an acre were planted with small sets, which Mr. May admits may be planted with advantage at less intervals than larger ones (3 and elsewhere), and also assuming that each of the small sets would give a proportionately larger produce (7), would it not clearly be a profit in the produce of the acre, and be particularly important to small growers, who purchase their Potatoes by measure, and who would thus obtain a greater number of smaller sets, and also to those who do not keep pigs, and might thus utilise all their sets, which were too small for the table? The word “produce” may possibly, as used in 7, refer to the number of tubers, which would, of course, alter the case; but the experiments being conducted in general with reference to weight, I should not think that an exception was made in this instance.

I will now state one or two facts which bear upon the subject, and are derived from experiments, or rather the trial of some different varieties in 1866, the following year to that in which Mr. May's experiments were made, and which year was in our neighbourhood rather a good one for Potatoes. It was then that I first tried Potatoes without earthing-up, but my gardener was wedded to the old system; each plan was tried with several varieties, and on the same piece of ground, but although the result was in favour of the old plan, I was convinced that the sets had not been planted deeply enough. In 1867 I took care that they were planted from 6 to 8 inches deep, and the result effected a complete conversion of opinion on that point. I should be glad to hear your opinion, though I feel almost sure you will advise deep planting and not earthing-up. The Potato which succeeded best in this way was Wheeler's Milky White. This is a first-rate Potato. A few Flukes came up the next year, small sets which were overlooked, having remained in the ground, and the average crop of these was 18 ozs. per set. Now, no small sets in Mr. May's experiments could well have produced this weight, none but small sets could have well escaped notice in my case, and the highest average in his experiments with 2-oz. sets was about 16½ ozs. I tried the following Potatoes:—Rivers's Royal Ashleaf, two varieties of Flukes (I do not know their names), Gloucestershire Kidney, Baron's Perfection, Flourball, Pheasant's Eye, and Snowball. According to my experience, small sets of the Gloucestershire Kidney produced a larger crop than the larger ones, and the same with Snowball; but I do not care about this variety, it is not sufficiently mealy. Baron's Perfection gave the largest crop at about 4-oz. sets.

I intend to make some more extended and careful experiments this year; but at present I cannot help thinking that

the best size to plant is from 2 ozs. to 5 ozs., that it is best not to earth-up, and to plant 9 inches from set to set in the rows, each row being from 18 to 20 inches apart.—W. S. R., *The Florence, Coleford, Gloucestershire.*

LAPAGERIA ROSEA AND LAPAGERIA SPLENDENS.

I AM glad to see that Mr. Douglas has been the first to write on the culture of these splendid plants, and I hope his remarks will be followed by others. I am the fortunate owner of two as fine plants as any in England: so says one who ought to know.

They have been left almost to themselves, and had plenty of water summer and winter. Many of my friends recommended rest; but the fact is, they would not rest since 1864, and were growing up to last May. I then experienced a sad fright—I thought my best plant was going to die, but no: it went to rest until the end of June, and in July began to show flower buds, and continued flowering up to Christmas. I bought it in 1857 when a very small plant.

Mr. Douglas speaks of seedlings at 2s. 6d., but I am afraid our friends will have a long time to wait before they flower. My plant above mentioned did not flower till 1866. It is *Lapageria rosea*. It evidently makes strong wiry roots downwards, and likes its crown kept high. I have seen a good many plants of it, but none of the vigour of mine. I do not find that it is subject to the attacks of any of the greenhouse pests mentioned, but in its younger years slugs were sure to find it out; it defies them now, for its stems are as tough as wire. I have just finished repotting one of my plants into a pot 2 feet in diameter—the largest I could obtain—and I carried out Mr. Douglas's advice with respect to soil. I should mention that occasionally I put a little Condy's patent fluid into the water. It sweetens the soil and stimulates the plant; and if any of your readers would try it on their *Primula* plants that have nearly done flowering, they would be astonished at the effect. I put in enough to make the water of a pretty pink.

As to the mode of training, I have the pots sunk into the table at each end, which is 14 feet long; a light wire arch is thrown across, so that one plant meets the other, the flower buds coming through and hanging down like so many scarlet bells. Any one purchasing a plant I recommend to buy a good plant well established.

Lapageria splendens flowers in clusters, whilst *L. rosea* has only one flower at the end of its stalk. The former has a long sharp leaf, whilst that of the latter is more round and something like the leaf of *Lapageria alba*. Any of our friends having plants of either must not lose heart at the growth not being rapid at first, for they will be astonished some day by seeing them throw up something like the head of an Asparagus. Mine last year threw up four the size of a man's little finger, and they are now 10 feet long.

I never knew a flower last so long as that of the *Lapageria* after it is cut. I gave a flower of it to a lady who wore it in her hair at a ball, next night at the theatre, and had it fresh still hanging on its stem a fortnight longer. It does not turn brown at the tips like the *Camellia*.

I have sent you a photograph of my plant. You can make what use of it you like. I should say that sometimes in winter the thermometer in my house has been as low as 32°. The plant seems to live in extremes.—W. A. O., *Sunderland.*

[The photograph shows a very superior specimen of *Lapageria rosea*; and beneath it sits its owner, looking as bright as if care had no chance with him.—Eps.]

IS A DRY OR MOIST ATMOSPHERE THE MORE CONGENIAL FOR SETTING MUSCAT GRAPES?

ON looking over your Journal for January 16th, I saw some remarks on the above-named subject by one of your able and experienced contributors. It has often occupied my thoughts, but I trust that the readers of these few remarks will not suppose that I am about to give a direct answer to Mr. Melville's question, but simply to state a few facts that have come under my special notice at different times.

At my present situation we have a house containing twelve Vines of Muscat of Alexandria, which every year are in flower in the month of April. I have noticed that during the whole time these Vines were in flower we have had dull wet weather;

this I have noticed for two successive years. There would be an occasional outburst of sun for a few minutes in the course of some chance day or two during the time, but nothing worthy of note; yet notwithstanding all this unfortunate, bad state of the weather, as many would term it, we never failed in obtaining a good regular crop of Muscats with well-formed bunches.

Another simple fact I wish to state is this. One end of the house is much warmer than the other part, on account of some extra piping branching from an adjoining house, consequently four of the Vines are rather earlier than the rest. These are in flower from a week to ten days before the others, and during this time the atmosphere of the house is kept in the same condition in respect to moisture as it was previous to the flowering, moisture being only slightly withheld just beneath the four Vines in flower, and these set their bunches much better than the Vines to which a rather drier atmosphere is afforded.

Again. I have particularly noticed that in a dull humid day, on gently shaking the Vine or bunch, the pollen will be seen falling in large quantities to the floor; whereas, on a bright clear day with a breeze blowing, the pollen will scarcely be perceived on shaking, and it appears much lighter, escaping upwards. Whether the pollen is as potent on a dull day as on a drier one is another question. I should for my own part say it is, if we are to take the setting of these Muscats into consideration.—H. BATTRAM, Foreman, Cyfarthfa Gardens.

ROYAL HORTICULTURAL SOCIETY'S EXAMINATIONS.

LAST week we announced the various success that attended the candidates at the last examinations of the Royal Horticultural Society. We now supply the number of marks which each candidate obtained.

CONIFERS FOR A CLAY SOIL.

WHILST thanking Mr. Robson for his hint as regards the fitness of *Taxodium sempervirens* for a clay soil, I beg to say that I have tried it, and that it grows most vigorously. I did not mention it in my last letter, as I was writing more especially about the *Cupressus macrocarpa*; but as my letter seems to have been useful, I will add a few more remarks upon those Pines which I have found grow well in a stiff clay.

As regards the *Taxodium*, the proper name for which I have been told now is *Sequoia* (Is this so?), I find that it is one of the fastest-growing Pines we have, but owing to its shooting very early it is nearly always checked by late frosts, and is much browned by March winds. One I planted in 1858, and moved two years afterwards, is now 17 feet high and 2 feet 4 inches round the stem at the bottom; but it has lost its leader twice if not three times, and in consequence has not increased in height at all for the last two years. Had it not been for this it would have been 4 or 5 feet higher at the least, at the rate of its growth in former years. With this exception it grows as well as I could wish, for neither the frost nor the winds seem to have any injurious effect on the vitality of the tree, and although it has not grown these two years in height, it has in girth. It grows also most freely from cuttings, and I have several specimens about 10 feet high, which I have taken as cuttings from the above-named tree, and which no one could distinguish from seedlings.

One remark of Mr. Robson's surprises me—namely, that in which he says that a specimen of *Cryptomeria japonica* was much injured by frost. Now, I have an avenue of them planted in 1858; and although they have made slow progress, being on an average about 10 feet high only, not a plant of them has ever been injured by frost in the least degree, though planted in the same stiff clay, and I fancied till now that they were one of the Pines that we might reckon as frost-proof. They are just now apparently "taking hold" of the ground, and I think they will make greater progress next year than they have hitherto. Some of them which are a little protected by a wood

near are doing remarkably well, so that the clay (drained) does not seem to disagree with them, though I fancy that they would do better in a lighter soil, but on the whole I have not much reason to complain of them. Now they are accustomed to the soil I think they will some day make fine trees, for in stiff clays such as this I find that one must not be too soon cast down at trees not taking. They are with some exceptions very slow at first, but when once thoroughly established make up for it afterwards. Amongst the trees, then, of the Pine tribe which I have tried that do well in a stiff clay, after *Pinus insignis* and *Cupressus macrocarpa*—which are, perhaps, the most vigorous of all, but unfortunately only half-hardy—I find *P. austriaca*, *Picea pinsapo*, *Taxodium sempervirens*, *Wellingtonia*, *Cupressus Lawsoniana*, *T. Lobbii* (both very vigorous), *Thuja aurea*, *T. glauca*, *Cryptomeria japonica* (fairly), *Juniperus glauca*, and the common Pencil Cedar all thrive.

With regard to what Mr. Chitty says, that his experience tells a different tale, and goes to prove that *Cupressus macrocarpa* is not hardy enough to stand such winters as that of 1867 in all situations—why, that was the very point my first letter on the subject went to prove. No one with his eyes open, after the experience of last winter, could be hardy enough himself to say that; on the contrary, it is quite clear that it is only half-hardy. I endeavoured to point out from experience, besides the fact of its flourishing so well in stiff clays, in what situations it was likely to succeed, and where it would probably fail.—A SOMERSETSHIRE PARSON.

P.S.—I have just planted a *Thuja gigantea*, thinking, on account of its name, that it would grow quickly and to a large size. Can you tell me to what height it is likely to grow? I have also two ten-years-old plants, raised from seed which I gathered from *Cypresses* growing over Shelley's tomb at Rome, that have grown well. One is about 9 feet high; the other, which was the better of the two, was cut very hard by the frost last year, but is still likely to do well, though I have been obliged to cut away 4 or 5 feet of it.

[Gordon in his "Pinetum" gives a very wide range of heights to which *Thuja gigantea* attains. He says it is "a noble evergreen tree, with an umbrella-shaped top, and straight stem when old, growing from 40 to 140 feet high, and from 3 to 5 feet in diameter." Its native habitat seems to be the banks of rivers.

—Eds.]

NOTES AND GLEANINGS.

FROM what we already know, there is every prospect that the ROYAL HORTICULTURAL SOCIETY'S EXHIBITION AT LEICESTER in July next bids fair to rival, if not to excel, that of Bury St. Edmunds last year. According to the last information the amount already subscribed by local effort amounts to £225, as against £197 6s. 6d. at Bury St. Edmunds. It must, however, be borne in mind that Leicester is the centre of a great manufacturing and wealthy neighbourhood, whilst that of Bury is merely agricultural; and we shall be much disappointed if the amount still to come from Leicester be not considerably in advance of that already named. We have no doubt it will be, and that Leicester will not fall short of any effort that may be expected from it.

—THE Midland Railway Company have agreed to convey all plants that may be exhibited at Leicester at the Royal Horticultural Show in July next for a single fare, which must be paid when the plants are sent; and if after the Show they continue the property of the exhibitor, they will be returned free of carriage.

—WE have great pleasure in announcing that the Cotton Supply Association of Manchester has presented MAJOR R. TREVOR CLARKE with an address and the gold medal of the Association for his researches in the hybridisation and culture of the Cotton plant. The medal is a beautiful work of art, and bears the following inscription—"Presented for the Successful Cultivation of Cotton to Major R. Trevor Clarke. Feb. 17, 1863." This needs no comment. All who know how assiduous Major Clarke is in the promotion of all that can benefit art, science, and industry, will rejoice to know that his labours have in this instance met with their just reward.

"CARTER'S PRACTICAL GARDENER."—Under this title Messrs. Carter & Co., of High Holborn, have issued a useful guide-book, arranged in the form of a monthly calendar of the operations in the fruit, kitchen, and flower garden, conservatory,

forcing houses, stove, Orchid house, greenhouse, and pits and frames, together with directions for the management of window plants. There are in addition remarks on pruning and training fruit trees, with several illustrations; on orchard-house management, on the preparation of Mushroom beds, and some other subjects.

MARRIOTT'S SELF-REGULATING BOILER.

In reply to "Rose," we have two of the largest-sized of this boiler at work here. My experience of them only extends to last November, during which time they have done their work so satisfactorily that I have formed a very high opinion of their capabilities and simplicity. I have had a fair share of experience with other boilers, and consider Marriott's superior to any I have before had in giving a more regular heat if attention is paid to the regulator. You can then have the water at the boiling point by opening the regulator to its fullest extent, or by closing it you can completely stop combustion, and, therefore, stop the circulation of the water in the pipes.

The economy of fuel is also great in comparison with the old saddle boiler, as we are enabled to prove by having three of them at work as well. One of Marriott's boilers can work 1700 feet of 4 inch piping as well as our largest saddle boiler can work 500 feet, and not consume any more fuel, although I must acknowledge that the former is rather more particular in regard to the quality than the latter. On the other hand, Marriott's when filled-up in the morning, if the weather is mild, requires no more attendance till about nine o'clock at night, than to set the regulator at whatever degree of temperature you require; whereas the old saddle-boiler may be set down as requiring to be looked to at least from eight to ten times in the course of the twelve hours.

Another great advantage of Marriott's boiler is its requiring no brickwork in the setting, as the tubes are encased in sheet iron and merely set down in the stokehole. Many thought the casing would become so hot that there would be a great waste of heat, but we find it quite the reverse, as so much heat is not given out as by an old furnace.

There are, however, a few drawbacks to this boiler. The first is the great depth of stokehole required; the second is, where coke is scarce, that I am afraid it will be difficult to burn coal in the furnace, but of the latter fuel for it I have had no experience.—JAMES STEWART, *Nuneham Park*.

THE ROYAL HORTICULTURAL SOCIETY'S EXHIBITIONS.

I HAVE read with much interest the observations of "ANOTHER F. R. H. S." in last week's Journal, on the Royal Horticultural Society's Exhibitions for 1868, and although I do not agree with him in all he has said in his communication, there is a great deal in which I quite concur, and which is in my opinion well worth the consideration of the Council and Fellows of the Society. The point to which I mainly refer is the encouragement that the Society has for some years past given to horticultural exhibitions.

Now, there are two views in which these exhibitions are popularly regarded—the one is as a source of revenue, and the other as an encouragement to horticulture. Let us see how far these popular views are correct. The former so long as it is successful is defensible; but whenever exhibitions become unremunerative, and a burden to a Society, then not only prudence but common sense would dictate their abandonment. So long as the Horticultural Society's Exhibitions were without a rival, and had the advantage of novelty and fine weather, they contributed very largely towards the Society's prosperity and usefulness, and after a successful season it awoke like "a giant refreshed," full of vigour, and, no doubt, well-intentioned designs. But the evil days of rivalry and competition arose, and from that time the Exhibitions both of the Society and its rivals, while they became important features in their constitution, were but the insidious flush that betokened disease and decay. All experience has proved this, and hence the popular idea that great exhibitions, as at present conducted, are advantageous to any society, is an erroneous one.

With regard to the second idea, that great exhibitions, as at present conducted, are an encouragement to horticulture, I hold it to be to some extent also erroneous. I should be sorry to say that they have no beneficial effect on horticulture, because I believe they have; but the question that suggests itself to me is, Would not smaller exhibitions, such as your correspondent ad-

vocates, be equally as stimulating to horticultural taste? If we take the magnificent specimens that constitute the collections exhibited at our great shows, we find that very few of them are grown by private individuals, but are shown by nurserymen and others with a view to trade advantages, and without any feeling whatever as to the advancement of horticulture, except in so far as they themselves are advanced also. Those that are generally shown from private gardens will on investigation be found to have very much of the same stimulus infused; the prizes obtained forming not unfrequently an important element in the gardener's wages, while the employer derives both the pleasure and the merit of having produced them. So far as horticulture, therefore, is affected by these large (and bear in mind, I am speaking only of metropolitan) exhibitions, I am of opinion that this second popular view is also erroneous. I am of opinion that smaller and less pretentious exhibitions would have even a greater effect in diffusing a horticultural taste, and encouraging the spread of practical horticulture than these great exhibitions have. When it is considered at how much cost and trouble the gorgeous plants exhibited at these great shows are produced, I am inclined to believe that so far as the masses of amateur horticulturists are concerned, they are rather deterred from following the example than encouraged to imitate it. Hence it is that I agree with your correspondent in advocating smaller shows, where smaller growers would have a field suited to their means, on which to enter the lists with each other, and contest the honour of having produced exhibitions not less meritorious, because they are less demonstrative and produced at a smaller cost.

It is upon this ground that I always advocate, while I admire and derive so much more pleasure and instruction from, the minor shows of the Fruit and Floral Committees, and the spring shows of the Royal Horticultural Society, than I do at any of the great exhibitions; and I am sure that if the shows indicated by your correspondent were to be submitted for the approval of the exhibitors, they would meet with a large measure of success. I refer more particularly to those which have been distinguished by the name of "Sweepstakes," and I venture to say that the forthcoming "Pelargonium Sweepstakes" will be the most exciting, as it will be one of the most interesting competitions of the season. And why should we not have more of these sweepstakes, augmented it may be in some way or another by the Society, in the same way as is done at horse races? There is something analogous to this practised in most provincial horticultural societies. Before an exhibitor can enter his plants, he must pay his "entry money," which goes towards the prize fund of the society. To me it is as unreasonable to expect the Royal Horticultural Society to bear the responsibility of all the prizes, as it would be for the Jockey Club to bear that of the Derby Stakes, which are well known to attain the enormous amount they sometimes do by the subscriptions of the owners when they enter their horses being added to the amount offered by the Race Fund.

As an amateur ardently devoted to the pursuit of horticulture, and one deeply interested in the prosperity of the Royal Horticultural Society, I hope that the time has come when something will be done to promote the extension of the one, and to secure the permanency of the other, and it is with the hope that both may be secured that I have ventured to trouble you with my views on the subject.—S. T. P.

GALVANISED WIRE TRELLISES.

WHEREVER galvanised wire trellises are attached to walls and employed for the purpose of training fruit trees upon, I think it may be safely stated that they have always given the utmost satisfaction to the fruit-grower. I have seen the trellis in use in several fruit gardens myself, and in not one instance did I ever hear it condemned; but, when the number of fruit gardens that there are in the kingdom is taken into consideration, how seldom is the trellis used for the above purpose. This consideration prompts me to ask the question—Why is it so seldom employed? I have tried to find a suitable answer, but without success. Its many good qualities make it appear to be almost faultless, for in whatever way it may be viewed, it shows a decided superiority over the other systems of training.

To those who have not given the subject any consideration, I hope it may be of service to them if I first say that the principal methods of attaching fruit trees to walls are by nailing with strips of cloth, and by fastening the branches to studs, which are fixed in the wall; and, in the second place, I will

mention a few of the points of superiority possessed by the trellis, and then compare it with the other methods.

I think I shall not do much wrong in mentioning the points of excellence in the trellis, if I begin by speaking of its appearance, for at the present day appearance goes a long way in almost everything. Now, no one can say that a well-wrought trellis neatly fitted and properly fixed to a wall, has otherwise than a neat appearance. For my own part I consider that it tends to improve the look of a wall rather than the contrary; but, independent of my own opinion, let a number of persons compare a well-trained wall of trees on a trellis with a wall of trees trained in either of the other modes, and I venture to state that the majority would be in favour of the trellis. However, as it is a point of taste, I will proceed to speak of the cleanliness of the trellis.

Every fruit grower makes cleanliness a most important object; for we all know that without cleanliness in fruit-growing success cannot be expected. Among fruit-growers it is a well-known fact that the strips of cloth which are required in nailing form excellent harbours for all kinds of vermin, their eggs, nests, and the like, all of which give the fruit-grower who trains his trees in that way continual work in order to keep them from overpowering him, while the trellis affords not the least shelter for anything of the kind. In this respect studs stand on about the same level as the trellis.

I will say no more about the cleanliness of the trellis, it would be useless after pointing out its excellence in that respect, but I will follow the subject to the next step, which will be the advantage the trellis possesses in assisting the trees to ripen both wood and fruit. In the first place I will mention that trellises are fixed about an inch, and sometimes more, from the wall, according to the kind of fruit cultivated. We are all taught that if well-flavoured and well-coloured fruit is expected, a good supply of air and light is essential. Now, by having the trees fixed a short distance from the wall, a good passage is allowed for currents of air to flow, and from the reflection of heat from the wall the air becomes nicely warmed, and this is highly favourable to the fruit and wood. This advantage is entirely lost in both the other methods, and the consequence is we find green, unripe blotches on one side of our fruit, as well as soft unripe wood on the back of the shoots.

At the present day economy of time and labour is so much studied, that a few remarks on the subject in connection with the trellis cannot be out of place. The use of the trellis in this respect is admirable. A great many persons, I know, hold as their firm opinion that the trellis is very expensive; but a well-wrought trellis may now be bought for a trifle, and when bought and fixed it is ever afterwards almost inexpensive; while in nailing, every year the nails are drawn and a fresh stock is required, as well as cloth, and it takes much time to cut up the cloth to the proper lengths for nailing. I feel sure that our young men could get through much more work in a given time by tying to the trellis than by either of the other modes, so that in this respect it may be justly said that the trellis is superior. As far as expense goes, the trellis amply repays the outlay in the excellence of the fruit.—*AGRICULTURIST*.

ROYAL HORTICULTURAL SOCIETY.

THE second Tuesday in February is always an eventful day in the history of the Royal Horticultural Society. Like all mundane things, societies never really stand still, but are either getting better or worse, and unless they be subjected to the process of reparation, there is no permanence or stability in their constitution. In these particulars the Royal Horticultural forms no exception. It is, however, to the elements infused in this process on which the healthful and enduring character of reparation depends, and hence this day on which the Society makes choice of the new elements that are to enter into its composition is one fraught with good or with evil for the future. That the choice which has been made is a good one, we believe is generally admitted; and with a Council so constituted, and with a statement so cheering as was on Tuesday submitted to the Annual Meeting, we look forward very hopefully to a career of great and lasting usefulness in days to come.

It must have been apparent to all who have given serious heed to the course the Society has recently been pursuing, that for some time past far more consideration has been given to subjects of a purely horticultural character than had for years previously been the case. Horticulture is in itself, perhaps, the cheapest and the most easily attainable of all luxuries, and

does not require a very large income to indulge in its pursuit; and so long as all superfluous expenditure is strictly watched, and no extravagant accessories indulged in, horticulture itself will never bring either a society or an individual to beggary. This the Society has found to be the case, for during the past year it has done more to identify itself with its legitimate object, and expended more money on purely horticultural matters, than it has done for years before; and yet in looking at the state of the finances as they are presented to us in this year's Report, we find that it has actually, taking the assets of the year into account, a balance in hand to begin the world afresh. This is, indeed, a novel state of matters, and indicates the beginning of a new existence. Three years ago—that is, at the close of 1864, there was a balance due to the Treasurer of £2784 10s. 3d., and liabilities amounting to £3000 on the revenue of the year; or, in other words, the expenditure exceeded the income by £5784. In that year £1984, including rent, rates, taxes, and insurance, was allowed for the maintenance of the Society's Horticultural garden at Chiswick, while £3702 was the portion allotted to the keeping of the ornamental garden at Kensington. At the close of 1865, there was a balance in hand of £12 3s. 2d., with outstanding liabilities of £369 2s. 8d.; and in that year Chiswick received £2236; and Kensington £3323. In 1866, there was due to the Treasurer, £203 17s. 7d., with assets to meet it of £375, and in that year Chiswick received £2475, and Kensington £3238. And now we come to this last year—1867, in which we find that in addition to the current expenditure, no less than nearly £1000 of old debts have been paid off; and although there is a balance due to the Treasurer of £375, there are assets on the year of £120 to pay it with. In this year £1387 was allotted to Chiswick, and £2526 to Kensington.

Nothing can be more cheering to the Fellows and to the lovers of horticulture than to see the old Society emerging from its long-enduring difficulties and again making its influence felt in that direction in which its mission lies. In giving these financial statements, we have done so, not with the view of making any invidious comparisons between the two garden establishments, for we consider that each has its own special object to effect, and we would not depreciate one at the expense of the other; but there is no disguising the fact, as will be seen from the statements we have made, that in former years the grants that were made to the one were out of all proportion to those of the other; and when it is considered that Chiswick is in fact the garden of the Society where its legitimate operations are to be carried out, and the results of its agency exhibited, where the whole of the plants are propagated and grown for the ornamentation of Kensington, and where so much is derived from the sale of the produce to the Fellows themselves, it did seem strange that a sum so paltry should have been doled out to it, while its more aristocratic sister received so large a portion. These facts show that so long as the Society confines itself to its own legitimate work, and limits its expenditure to those objects which come most within its province, there is no inducement and less temptation to fall into difficulties than when trying experiments on the best methods of amusing a miscellaneous multitude.

And now, after what passed at the Meeting, it is our duty to refer to the agency by which this new condition of things has been brought about. It would have been a pleasure to have done so even if the question had not been so publicly raised; but after the observations which Mr. Liggins, for his own sake, so unfortunately made, it is only justice to Colonel Scott that it should be publicly known that all this beneficial change in the Society's condition is due entirely to his hard work and skilful administration since he was elected its Honorary Secretary in the spring of 1865; and when we have said that, we consider it a sufficient reply to Mr. Liggins's inquiry as to Colonel Scott's qualification to hold the office which for the Society's interest he fills so well. If Mr. Liggins has, as he says, been "a Fellow for years," and has manifested during all that time the interest in the Society he now professes, it should have been part of his duty to have at least been able to identify Colonel Scott, and to have assured himself of the services he was rendering, before he made such allusions towards a gentleman who gives so much of his time, and, as we know, sacrifices much of his comfort to serve the Society.

Mr. Liggins, in his speech, said "they wanted to know if he was skilled in horticulture," and "they wanted a man at the head of the department who was practical." He did not state in what sense he intended his observation to apply, nor what direction the practice should take. If he meant it in a general

sense, we do not know any one to whom the term is more applicable than it is to a highly educated Engineer officer, whose training in science and administration, as much as in engineering, is essentially practical. But if he meant it to have a professional signification, and that the Secretary of the Royal Horticultural Society ought to be a professional horticulturist, he is asking for what, during the whole existence of the Society, has never been. One of the most popular and useful Secretaries the Society ever had was a brother of the present General Sabine. This gentleman was not a professional, but an amateur horticulturist, as Colonel Scott is; and his profession, we believe, was that of a Surveyor of Taxes. Dr. Henderson was not a professional horticulturist, and we are sure that neither Mr. Benthall nor Dr. Royle would acknowledge to be "skilled in horticulture;" indeed we doubt very much if either of the latter knew as much about horticulture as the present Secretary does. But we need not go through the lists for the purpose of showing that the office of Secretary need necessarily be filled by a professional horticulturist. What the Society really wants is a gentleman of administrative ability, who can and will bring that ability to bear on the management of its affairs, and particularly on its finances; and we have no hesitation in saying that never since the Society was instituted has it been so highly privileged in this respect as it is now, not even excepting that period when its affairs were under the direction of the much-lamented Mr. Sabine.

ANNUAL GENERAL MEETING.

The Annual General Meeting of the Royal Horticultural Society was held on Tuesday, and there was a rather smaller attendance of Fellows than usual.

In the unavoidable absence of his Grace the Duke of Buccleuch, K.G., President of the Society, the chair was taken by Mr. W. Wilson Saunders, who was supported by General Grey, Lieut.-Col. Scott (Secretary), Major Trevor Clarke, Rev. J. Dix, Messrs. F. Brandreth Gibbs, G. F. Wilson, A. Murray, and H. Cole, C.B.

Mr. G. E. Blenkins and Mr. R. Fortune were appointed Scrutineers of the ballot for the election of members of Council and officers for the ensuing year.

The Assistant Secretary, Mr. James Richards, read the minutes of the last meeting, which were approved and confirmed. The Assistant Secretary then, at the request of the Chairman, read the Annual Report.

The CHAIRMAN said it became his duty to move "that the Report just read be received and adopted;" but before doing so he would be glad to hear anything which any of the Fellows might have to say upon it.

Sir ROBERT MONTGOMERY, Bart., observed there was a notice given of a Horticultural Exhibition at Leicester, and it would, he considered, be necessary for the Fellows to have some details.

The CHAIRMAN was anxious to afford all the information in his power, and begged to inform the hon. baronet, that as regarded the Exhibition at Bury St. Edmunds, the Council were very much satisfied with it, although, as set out in the Report, there were several drawbacks. The weather was very bad, but at the same time the number of people that flocked to the Horticultural Show was so large, that a great deal of money was taken, and some £200 or £300 added to the funds of the Society. There having been a good profit there, it was thought by good management a similar show might be carried out at another place, and, with increased experience, at a less expenditure. The Council, therefore, did not hesitate to throw themselves in with the good people at Leicester, and there they were received with open arms. They (the Royal Horticultural Society), had made every preparation to carry out the Show, and the thanks of the Society were eminently due to one member of the Council, Mr. Brandreth Gibbs; and they believed it would be, and should be glad to see it, up to any show hitherto held [hear, hear]. The Leicester people have come forward in a very handsome manner. The Society had received a letter from there, which he (the Chairman) would read, and which would show the earnestness that was being thrown into the matter. The letter was as follows:—

"Leicester, 10th February, 1868.

"MY DEAR SIR,—We have a meeting to-day to receive the collecting books for special prizes for the Royal. The total amount to the present time is £225, and many books have yet to be returned. I intended to have sent a copy of the prizes by to-night's post, but the meeting lasted so long, and I find it will take some time to arrange, that I must defer it. Several of the collectors asked for more time. I told them that it was imperative that the Schedule should be issued at once. I intend having something for the *Chronicle* this week, to stir up our Nottinghamshire neighbours. I invited Mr. Lowe to be with us to-day, but he did not turn up, nor did he write. Messrs. Ingram, Sage, and Henderson gave us a good account. The guarantee fund is complete.—I remain, yours truly,

(Signed)

"James Richards, Esq., Royal Horticultural Society."

So that the Society would see that at the present time they had more prizes already than last year, and he (the Chairman), believed that the £225 spoken of in that letter would be largely augmented. As far as appeared to the Council, all the arrangements at present seemed

very satisfactory; but there was another letter, which he (the Chairman), would like to read to the Meeting, as it would show still further how well the affair was working. That letter was in the following terms:—

"Midland Railway, General Manager's Office, Derby,
10th February, 1868.

"SIR,—In reference to your letter of the 18th December, addressed to the Secretary, I have pleasure in informing you that in the case of plants, &c., intended for exhibition at the ensuing Show of the Royal Horticultural Society, the Midland Company will be able to afford the usual special facilities granted on such occasions—viz. the full ordinary rates to be charged to the Show, but the plants, &c., to be returned free, providing they remain the property of the sender.—I am, your obedient servant,

(Signed)

"JAMES ALLPORT, Manager."

"James Richards, Esq., Royal Horticultural Society, South Kensington."

All that showed a great desire on the part of those connected with the Show at Leicester in any way to make the visit of the Society as satisfactory as possible, and he (the Chairman), had no doubt it would tend to the production of horticultural exhibitions in other parts, which must do great good, for it would extend into the provinces a knowledge of many of the Society's finest plants; it would enlarge their sphere of usefulness, and increase their funds. He (the Chairman), should add that these Shows were held on the principle of taking an equal risk and dividing an equal share of the profits with the local Society. This course would be adopted at Leicester, so that the members would see the Local Committee were as much interested as the Horticultural Society themselves in promoting and extending the usefulness of the Show.

Mr. HENRY LIGGINS rose to make a few observations on the Report. They had had before them a report of considerable length, embracing many features, and there were also voluminous accounts. These he considered might very easily, and without any great stress of work upon the officials, have been circulated among the members some time before that meeting. That not having been done, he did not think they were in a position to criticise the accounts; and these ought not to have been put into their hands at that meeting for the first time, thus leaving them without the opportunity of perusing them. He thought that in future (and he was not placing the slightest opposition to the passing of the Report), the Report ought to be circulated a fortnight at least previous to the meeting. It was the practice at railway meetings to do so, and he thought it would be more satisfactory in their case. With regard to the money paid to their officers, he did not see a single reason in the world why they should not appear on the balance sheet. He should like to know what they paid their Secretary (Lieut.-Col. Scott, of the Royal Engineers), who might be in the room and yet had not the courtesy to read the Report, but placed it in the hands of the Assistant Secretary. The latter gentleman he always found doing arduous, important, and serviceable work for that Society. They wanted a man at the head of the department who was practical, and who should consider it his duty to attend the meetings and read the Report. For what he knew, the Council might have got the best man, but he (Mr. Liggins), did not know anything of him. They wanted to know whether he was skilled in horticulture, and whether he was skilled in general management. What were his avocations and salary? At present there was an unfavourable silence about them out of doors, and he felt he could not answer that silence. He should like to speak in the highest praise of every officer of the Society, and that was the reason why he asked his present questions. It behoved them to take care of their resources. They stood on a very precarious footing, and they should not allow themselves to be lax in their dealings, seeing that they were opposed so strongly by the Crystal Palace, the Botanic, and other Societies. They might find themselves in an unpleasant position with their great work at Chiswick, which, however, at present was in a state highly creditable to the Council, to whom they were also much indebted for the great diligence they had displayed in getting up those very charming afternoon meetings.

Mr. HENRY COLE, C.B., said he was not sure that they had had the advantage of the last speaker's presence before; but at all events he (Mr. Cole), had been present at a great many meetings of the Society, and if he was not mistaken he had never before seen him at the meetings, so that it was not surprising he (the last speaker) had not seen Colonel Scott.

Mr. LIGGINS.—I have been a Fellow for many years.

Mr. COLE did not know whether his observation was apt or not, but he was stating a fact that he did not know whether they had had the benefit of that gentleman's experience. He dared say if the last speaker had been present on other occasions he would have seen that they were following the ordinary precedent with respect to reading the Report; and within his (Mr. Cole's) experience, the Society's accounts had always been presented in the way they were now. He rather agreed with Mr. Liggins, that if they had not all been great conservatives it might have been expedient for them to issue the accounts before the meeting; but so long as he (Mr. Cole) was a member of the Council he should vote against any change in that respect. Mr. Liggins had objected to there being nothing in the accounts about the salary of Colonel Scott, of whom he very properly said he "knew nothing." They were asked why they took Colonel Scott as Secretary, and what was the stupendous salary they paid him. It was very desirable to have a gentleman who would pay a great deal of attention to his duties; and he also might consider, as probably Mr. Liggins

did, that paid services were much better than unpaid services. Mr. Liggins had considered it right to throw a slight upon their Secretary because he had left the reading of the Report to the Assistant Secretary. If his (the speaker's) memory was not bad, the Assistant Secretary had always read the Report, and he recollected that Dr. Lindley when Assistant Secretary always read it. Now, he would give a reason why their Secretary should not read the Report, and it was this—Colonel Scott had been doing them the favour of looking over their affairs, and they paid him nothing for doing so [applause]. They therefore had no right to call upon him to do anything. Of his own good will and competency Colonel Scott was prepared to do anything for them; and instead, therefore, of asking inquisitorial questions of "What duties did he discharge?" and "What amount of salary was he paid?" Mr. Liggins ought to have informed himself whether he *was* paid, and ascertaining the fact that he was paid, Mr. Liggins might then have been justified in asking how much. But it happened that Colonel Scott was paid nothing, and he did not think Mr. Liggins was entitled to ask any questions about the duties discharged. He (Mr. Cole) had no doubt that services to be responsible should be paid for. They had been asked why they had chosen Colonel Scott to fulfil the duties of Secretary. He answered, because Colonel Scott was the best man, and he was willing to give his services unpaid. Colonel Scott was a man of science and administrative ability. "The proof of the pudding is in the eating;" and he (Mr. Cole) did not hesitate to say that, long as the Royal Horticultural Society had been established it had never as favourable a balance sheet as at the present moment, and it was the first time in his recollection that the Society had cleared off a great deal of its liabilities. He was much obliged to Mr. Liggins for being inquisitive and giving him (Mr. Cole) an opportunity to vindicate the character of his friend. In the matter of elections they had followed the course adopted for a great number of years. Their Secretary was not a paid Secretary, and it had been the custom for years for the Assistant Secretary to read the Reports; and if they spent a fortnight in investigating the accounts he did not think they would be in a more satisfactory position than at present. He thought it would be sufficient to take the fact as it stood, that during the past year they had paid off £900 without incurring any liability [applause].

Mr. LIGGINS did not think it was right of a fellow "Fellow" [a laugh], to stigmatise his inquiries as "inquisitorial." He thought he had a right to ask questions; and really he knew no more about Colonel Scott than "the man in the moon." He (Mr. Liggins) had always found their Assistant Secretary a gentleman of intelligence, energy, and activity, and who was always at his work. He did not like honorary service; and he should like to have a paid secretary. He wanted a gentleman who was able to draw up a report; and he did not see any particular merit in the drawing-up of that Report. What he (Mr. Liggins) wanted was that the accounts should be furnished earlier, so that the members might see what was in them, and the same with the Report. It was no use telling him that things were as good as they used to be, he wanted them better than they were [hear, hear] even at present, and it was clear that others on his (Mr. Liggins's) side of the room adopted similar views. He remembered Dr. Lindley, who was a very able scientific man, giving lectures some twenty-five years ago, and he thought it was quite proper that he should have the assistance of a younger man to read; but, if he was not mistaken, he had heard their late Secretary read the Report. By his previous remarks he did not intend any offence, as he was entirely ignorant, and was simply asking for information; therefore he did not think it right for a member of the Council to say that he was impertinent.

The CHAIRMAN said they had never had a more efficient Secretary. Colonel Scott was a man of science, capable of mastering accounts, and thoroughly devoted to the advancement of horticulture.

Mr. BLENKINS had been present at nearly all the Committee Meetings, and he only knew their Secretary to be once absent from his post.

Mr. LIGGINS.—I do not know Colonel Scott; I never knew him, nor do I know any gentleman on the platform.

Mr. BLENKINS wished to say a few words respecting the report of the Chiswick Board. He observed that the Directors said "They would have desired to have effected something more than has been found possible in regard to the keeping of certain portions of the garden; but the labour rate at their disposal has proved insufficient for the purpose, and they therefore recommend a slight increase of expenditure under this head." He (Mr. Blenkins) had no doubt—indeed, there could be no doubt, they had all enjoyed their visits to Chiswick; but whenever they had done so they would not have failed to observe the quantity of waste land at the sides, which might have been brought into successful cultivation. He thought it was extremely desirable when the finances of the Society were better, that something more should be given to the support of Chiswick Garden. They would be glad to see that waste land cultivated, and they would find it to be a remunerative step. He saw the revenue was greater than on former occasions, and he thought a few hundred pounds spent on the waste land that was now perfectly unproductive, would bring in a good amount of funds to the Society. These who made periodical visits to Chiswick Gardens would appreciate the advantages of such a step, and he therefore trusted that the recommendations of the Chiswick Board would receive the support they deserved.

The CHAIRMAN said as far as their means went they would endeavour

to carry out the recommendations of the Chiswick Board. They, as a Horticultural Society, would not be able to carry out their labours without Chiswick, and the more money they expended on Chiswick the more they would advance horticulture. He should be glad to see them have the means at their command to do so. If they were successful (and their funds were gradually increasing, so that they would have more at their command), he thought the Council would put to the Chiswick account more than ever.

Mr. EDGAR BOWRING, C.B., was anxious to say a few words as to the admirable way in which the duties of Secretary were fulfilled by Colonel Scott, although he (Mr. Edgar Bowring), could not go quite the length of some previous speakers, implying that the gallant Colonel was the best Secretary they ever had, for he remembered the able tenure of that office by their esteemed friend and Chairman, Mr. Wilson Saunders [hear, hear]; but that the duties were most efficiently performed by Colonel Scott no one could for a moment doubt. He (Mr. Edgar Bowring), was glad to be able to speak of the amicable arrangement that had been come to with the International Horticultural Committee, and the satisfactory proceedings which had resulted, but had hardly seemed probable. Both parties had done him the honour to invite him to attend, *amiciis curis*, in which capacity his first advice was to let bygones be bygones. All agreeing in that spirit, the upshot had been the investment of the balance of £1850, which had been devoted to the purchase of the library, which he said would prove of the greatest possible service to the Horticultural Society. It had been invested in trustees, and would remain their property as long as the Horticultural Society remained tenants of their present grounds. He hoped they would have its contents added to by gifts and bequests. Referring to the accounts, he did not see any balance in their favour, but they had got off a great deal of debt. Their receipts had been influenced by the doubtful weather and the continued effects of the financial panic. He trusted that their future financial position would be satisfactory. He presumed the Council had not been able clearly to see their way whereby the debenture-holders at 4 per cent. could be altered in favour of the Society by giving more free admissions; but he (Mr. Edgar Bowring), had no doubt that if anything could be done it would [hear, hear]. The only item of expenditure that he took exception to was that for repairs, which he considered a good deal too small, and they might depend upon it that if they did not keep up their repairs their negligence would find them out some day. He might remark, adverting to some observations by a prior speaker, that according to their bye-laws, the accounts were to be ready a week before the day of meeting, when any gentleman, by applying, could have a copy of them supplied to him.

The CHAIRMAN said the sending-out to the members a copy of the accounts before the meeting would be taken under the consideration of the Council.

Major TREVOR CLARKE in referring to what fell from Mr. Liggins, said he had no doubt that gentleman had spoken in honest ignorance of what Colonel Scott had done for the Society; but when allusion was made to a certain number of persons behind him having a fellow feeling, he (Major Clarke), would say that the vast majority of that Society knew Colonel Scott very well, and they would endorse the opinion that the Society were much indebted to Colonel Scott for the financial and social position they enjoyed, and they must feel convinced that he had saved the Society a great deal [applause].

Mr. LIGGINS would merely observe that there could be no difficulty in the accounts and Report being sent to the members, as they were ready, it now appeared, a week before the meeting.

Mr. MURRAY.—It was purely a question of expense of postage, and whether it was necessary.

The Secretaries then delivered in the balloting papers, and the list of officers declared to be elected for the ensuing year is as follows:—President, His Grace the Duke of Buccleuch; Treasurer, Mr. John Clutton; Secretary, Lieut.-Col. Scott, R.F.; Expenses Committee-men, Mr. John Clutton, Lieut.-Col. Scott, R.F., and Mr. Henry Cole, C.B.; Auditors, Mr. James Nicholson, Mr. John Gibson, and Mr. Robert Hudson, F.R.S.

The retiring members of Council being Viscount Sandon, Mr. Wentworth W. Buller, and the Rev. Joshua Dix, the gentlemen elected to succeed were Mr. John Clutton, Mr. J. Russell Reeves, F.R.S., and Mr. William Marshall, of Enfield.

Mr. LIGGINS having seconded the motion for the adoption of the Report, it was carried unanimously.

Mr. LIGGINS then said he had much pleasure in proposing a vote of thanks to the Chairman, Council, and Lieut.-Colonel Scott, the Secretary [cheers], for the advantages which the Fellows had derived from their services.

Captain DOWNMAN seconded the motion, which was carried by acclamation.

The CHAIRMAN, in acknowledging the compliment, said he believed the interests of the Society were well cared for by the Council, who spared no trouble to fulfil their duties.

The business of the Meeting then terminated.

REPORT OF THE COUNCIL TO THE GENERAL MEETING.

1. The Council is happy to be able to make, on the whole, a satisfactory Report to the Fellows of the present state and future prospects of the Society. The subscriptions received from Fellows during the

past year amount to £8027, as compared with £8176 in 1866, £7975 in 1865, and £7840 in 1864. One gratifying sign of growing confidence in the future of the Society is the fact of twenty-five old Fellows of the Society, who had resigned, having again become members.

2. A new and most legitimate and promising source of future income has also been opened, while a wider sphere has at the same time been given to the operations of the Society. The Exhibition at Bury St. Edmunds, which was announced in last year's Report, has more than answered the most sanguine expectations of its promoters. In spite of unpropitious weather, it proved not only eminently successful as a Horticultural Exhibition, but also as a financial speculation. The Council confidently anticipates a still more decided success from the Show which it is proposed to hold this year at Leicester; for there is no reason to doubt that the interest, great as it was, which was taken in the success of their Show by the horticulturists of Bury St. Edmunds and its neighbourhood will be at least equalled at Leicester, while the population of the latter town is very much greater. The deputations which was sent by the Society to make the necessary arrangements there met, moreover, with the most gratifying assurances of support; a guarantee fund was raised in the town without any difficulty, and special prizes to a large amount have already been promised. The Autumnal Provincial Shows thus bid fair to become one of the most effectual and popular means of furthering the objects for which the Society is incorporated; and, while they may be expected to add considerably to the funds of the Society, will tend to encourage and promote the study and love of horticulture throughout the country.

3. The Council refer also with the most lively satisfaction to another evidence of the increasing usefulness and spreading influence of the Society. There are now no less than fifty-two Floricultural and Horticultural Societies in union, and of these twenty-four joined during the past year.

4. The accounts of the Society, which have been placed in the hands of the Fellows, will further show that the Council did not take too hopeful a view of the affairs of the Society when at this time last year they expressed the opinion that, though requiring strict economy, its affairs were in an encouraging position; notwithstanding all the drawbacks arising from the serious monetary depression of the last two years, it will be seen that its revenue for 1867 has considerably exceeded the outlay necessary to carry on its work. The only items on which the Council have permitted any increase of expenditure over that of former years are those relating to Chiswick Garden; and the Fellows will observe that the Chiswick Board state in the annexed Report that, even with this increase, more funds are wanted to bring the Society's working at that place into full efficiency. The Council, therefore, in the belief that a judicious outlay in the manner suggested in the Report alluded to will result in increased produce, as well as increase of general usefulness, have made some further additions to the Chiswick labour item for this year.

5. The labours at Chiswick during the past season have met with much success. M. Bausé, the foreman of the Floral Department, has succeeded in the production of an entirely new race of golden-leaved Caladiums; and in the Pomological Department many interesting trials of varieties of Fruits and Vegetables have been carried out, including one of a valuable collection of Figs. The Fellows are referred to the Report of the Chiswick Board of Direction for fuller information on these subjects, and their attention is particularly called to the request of the Board that any Fellows of the Society who may possess uncommon and attractive species of hardy herbaceous perennials will aid the Chiswick collection of plants of this character by contributions of such as they can spare, or by gifts of seeds.

6. The Council call attention to the annexed Report of the Examinations in Horticulture for the past year. The success of the Chiswick students is particularly gratifying; and the Council have now, in compliance with the recommendation of the Horticultural Directors, arranged for providing a few Lectures and Demonstrations in aid of the practical studies of these young men.

7. The Meetings of the Fruit and Floral Committees have been as usual very well attended during the past season, and the Council have reason to believe that the valuable labours of the gentlemen composing these Committees greatly influence the progress of Horticulture throughout the country. The Afternoon General Meetings, also, which follow the Committee Meetings, have been most successful, both as respects the appreciation of them by the Fellows and the subjects which have been discussed. The results of the various Meetings and Exhibitions of the Society will appear in the forthcoming number of the Journal, edited by the Rev. M. J. Berkeley.

8. The four days' Show of June last, held in the Great Tent, was a great success in a Horticultural point of view. Various opinions for and against the continuance of a Show beyond the first or second day have been offered; but as yet the Council see no reason to regret that they have made the experiment, and they propose to repeat it this year. The Exhibition of June last was indeed continued for a whole week, the greater number of the Exhibitors having at once (in many cases at considerable inconvenience), acceded to the Council's wish to have it kept open on the Whit Monday. The Council have also added a second day to the Special Prize Show. The only other alteration of the last year's programme is the breaking-up of the two Spring Shows into three, with a slight addition to the total amount offered in prizes. The charming fortnight's Show of Spring Flowers will be re-

peated on an increased scale. The Society is under great obligations to Mr. W. Paul for the spirit and energy he displayed in this Exhibition, which has now become so prized a feature of the Society's yearly arrangements. Messrs. Lane & Son, Berkhamstead, will also make an Exhibition in the Arcades of their Plants and Flowers during the month of April; and Messrs. Waterer & Godfrey's Exhibition of Rhododendrons, discontinued last year in consequence of the damage done by the severe frosts, will, the Council hope, again be counted this year among the attractions of the Gardens.

9. The Council have, in former Reports, made known to the Fellows that the Exhibitions of the Society are no longer a source of income as formerly, but now involve a considerable loss. Each season renders a recovery from this condition of things more unlikely. The expenditure on last year's Exhibitions was £1727 18s. 3d.; the receipts only £1102 7s. 6d. It is manifest, therefore, that the Society must proceed with caution in again attempting any increase in their number. Nevertheless, the Council think very well of the proposition that has been made to them to add to their programme some small Shows of special subjects, which would otherwise escape competition, owing to their time of flowering not coinciding with the London season; and they will be quite prepared to give facilities for holding such minor Shows as may appear to have interest for a sufficient number of cultivators and admirers to give a probability of success. The best test of such interest would be a proposition on the part of horticulturists to make special Shows, as has already been done by the cultivators and admirers of Zonal Pelargoniums. The Zonal Pelargonium Show of last season, will this year have grown into a very important Exhibition.

10. The Committee of the International Horticultural Exhibition have generously applied the whole of their remaining surplus funds to the acquisition of a Library, to be held in trust for the use of the Society. The only condition annexed is one which the Council are very glad to accede to—viz, that the Library, under proper restrictions, shall be open for consultation to all Horticulturists and Students who may wish to refer to it. The Trustees consist of three officers of the Committee and three officers of the Council, who are to appoint a seventh member. The arrangements of the Board include the purchase from the Society of the Lindley Library. This Library, and also a collection of works the property of the Society, will shortly be placed in the Council Room.

11. In their Report, presented in the year 1866, the Council made allusion to the contemplated erection of the Royal Albert Hall of Arts and Sciences, as likely to add an additional attraction to the gardens of the Society. During the past year the foundation stone of the building was laid by Her Most Gracious Majesty the Queen, and its walls are now fast rising. The Council are making arrangements with the Provisional Committee of that undertaking, from which mutual advantages will be derived. These arrangements will include convenient access to the Hall from the Society's Conservatory.

12. In conclusion, the Council have pleasure in announcing that the claim put forward by them for the recognition of the important services to Horticulture of the old and valued officer of the Society, Mr. Thompson, has resulted in a subscription which at present amounts to £360. Some account of his labours, and a list of the subscribers, were given in the Proceedings of the Society issued last month.

REPORT TO THE COUNCIL FROM THE CHISWICK BOARD OF DIRECTORS. DECEMBER 1867.

1. The Directors have the satisfaction of reporting that the Chiswick Garden has been thoroughly utilised during the past season, and that the cultural results, under the efficient superintendence of Mr. Barron, have been fully equal to those of former years. They would have desired to have effected something more than has been found possible in regard to the keeping of certain portions of the garden, but the labour rate at their disposal has proved insufficient for the purpose, and they therefore recommend a slight increase of expenditure under this head.

2. The experiment which has been made with reference to the employment of Students for the performance of a portion of the work of the garden has, so far fairly answered the expectations of its promoters; and the Directors, but for the outlay involved, would willingly extend it, so as to offer its advantages to a larger number of young men anxious to use the best means of advancing themselves in their profession. They, however, having past experience in view, think it would be advantageous to provide for the entry of somewhat younger men than the present regulations will admit. They also think that a few Lectures and Demonstrations in aid of the practical studies of these young men, such as were originally contemplated, would now prove a valuable aid to them.

3. The Directors trust that the Society may rely on a continuance of the aid which has been so generously and efficiently afforded to the Chiswick collection by those gentlemen who have obligingly contributed novelties for the various trial collections, since they believe that these experimental trials have more effectually and widely diffused a correct knowledge of the recent acquisitions for the Flower, Fruit, and Vegetable gardens than could have been brought about by any other ready means. They are highly gratified to be able to state that these trial collections, and the standard sorts grown for comparison with them, are sought for with much interest by numerous visitors at the proper season.

4. As regards the Floral Department, some new houses have been completed, and others efficiently repaired, so that the Superintendent has now better accommodation than formerly for growing flowering plants, the chief demand for which is to aid in the decoration of the conservatory at Kensington throughout the year. With this latter object in view, various additions have been made to the collections of stove and greenhouse plants.

5. During the past year, 7571 plants have been grown for distribution to the Fellows by ballot, and 125,512 packets of vegetable and flower seeds have been also made up and distributed; besides 1714 plants and 12,512 packets of seeds which have been sent out to the various Societies in union.

6. The provision of material for the decoration of the garden at South Kensington has been greatly extended, and has correspondingly increased the expenditure at this establishment, both as regards labour and glass accommodation. No less than 15,227 plants thus reared have been contributed by Chiswick for this purpose during the present year.

7. In addition to the plants referred to in the foregoing paragraphs, 927 varieties of plants, old and new, such as Pelargoniums, Verbenas, Tropaeolums, Calceolarias, &c., have been grown for judicial examination by the Floral Committee. The groups of the older kinds, grown as standards for comparison, were very attractive in their season; but the newer varieties have been less successful, owing chiefly to two causes—the late date and weakly condition in which, in too many cases, the plants are received, and the unpropitious weather of the past summer. It is hoped that in future the plants may be obtained earlier in the season, in better condition, and that more extended and useful results may be obtained.

8. Attention has been given to Hybridising, and the rearing of novelties for the use of the Fellows; and the Directors are highly gratified to be able to report that M. Baume, the foreman of the Floral Department has won for himself the credit of having produced an entirely new race of golden-leaved Caladiums. A very large number of hybridised Caladiums has been reared, showing great variety in the colouring and marking of the leaves, and including amongst them several highly ornamental novelties; but the production of the golden-leaved forms (which include some three or four distinct variations), has been the most marked instance of success. Besides these, some promising Variegated Zonal Pelargoniums have been obtained; as well as a crop of hybridised forms of Coleus, and of some other plants, which, however, are not as yet sufficiently developed to show whether any improvement has been gained.

9. Sympathising heartily with the expressions of regret which are frequently heard as to the neglect into which hardy herbaceous perennials have been allowed to fall, to the curtailment of the bounty and interest of English flower gardens, the Directors have set about the formation of a collection of these plants, with the view to revive the taste for them, by facilitating the selection of those best adapted for particular seasons and particular situations. To this end, they hope to secure examples of all the more ornamental and really interesting species. As plants of this character are frequently preserved in country gardens after they disappear from general cultivation, and thus become difficult of access, the Directors trust that the Council will urge upon any Fellows of the Society who may possess uncommon and attractive species the advisability of adding to the Chiswick collection, or contributing plants or seed of any such which they can spare. The Directors anticipate that much interest will be excited by this collection, and that it may induce many Fellows to introduce into these Gardens that much-maligned institution, "the mixed border," from which, however, they feel satisfied that a large amount of interest may be derived by the lovers of flowers.

10. A collection of subterranean plants has been brought together, and during summer forms a very interesting feature along one of the principal walks in the garden.

11. In the Pomological Department, the Board have to report that, by the removal of the house from South Kensington to Chiswick last spring, the valuable collection of Figs has been properly accommodated, and almost the whole of the variety are in full bearing. During the past season several new and excellent varieties have been discovered, and numerous synonyms have been detected. A report on the varieties which have fruited is in preparation.

The collection of Strawberries, to which reference was made in last year's report, as having recently been acquired and planted, is now in a most satisfactory condition. Last summer the greater number of the varieties produced fruit, but as it is anticipated that from the vigorous condition of the plants and the encouraging prospects for next summer, the whole will then be in bearing, it will be better to make a report on the whole after comparing them with each other and ascertaining their relative merits.

12. During the past year the Board instituted a trial of all the varieties of Grapes that are included under the group of Chasselas. These were grown in pots in a heated pit, but the experiment was not sufficiently successful to warrant a report being made on the various varieties forming the collection. It is, however, intended to repeat the experiment next summer.

13. A trial of all the varieties of garden Peas, as highly successful, and tended to the acquisition of much valuable information relating to the different varieties, and especially to those of recent introduction. The same success attended the trials of Broadbeans.

and Lettuce. On all of these subjects complete reports have been prepared.

14. Another of the most important functions of the Chiswick Garden has been liberally worked in the distribution of grafts of fruit trees, of which no less than 1,500 parcels have been received by Fellows of the Society during the past season.

15. The demolition of the old and diseased fruit trees which occupied some of the belts in the kitchen garden having been attended with beneficial results to the garden, the Board would suggest to the Council that the greater portion of the old orchard of unproductive standard trees should be trenched over; and the ground appropriated to the reception of the young trees raised from scions of those which had been destroyed, along with others forming a numerous collection which have been obtained at various times from the pomologists of the continent of Europe and the United States of America. These old orchard trees, as they at present exist, are perfectly worthless, and occupy a large extent of ground, which is thereby rendered unproductive. If this were done, not only would there be room for the young plantation of pyramidal and bush fruit trees, but space available also for the production of vegetables and the more common fruits for which there is an increasing demand by the Fellows; while there is less inquiry for Grapes and the higher class of fruits.

16. The Peach wall, which at one time was the pride of the garden, has for some years been gradually losing its interest; the trees, many of which are equal with the wall itself, having fallen into the decrepitude of age, and occupy space which might be more serviceably employed. The Board would suggest that these old trees be removed, and their places filled with young trees of choice varieties, which will serve not only as a source of income by the sale of the fruit, but as examples of the different methods of training and the most approved modes of pruning wall-fruit trees. As the trees at present exist, they afford no instruction in this latter respect; and it is most important in an establishment like the garden of the Society, in which experimental and educational purposes form so important a feature, that the training and pruning of fruit trees should be on the most approved and modern principles.

EXTRACT FROM THE REPORT OF THE POMOLOGICAL EXAMINER

The examinations of gardeners as candidates for the Society's certificates, which were commenced in 1866, have been continued during the past year with the most satisfactory results. One of these took place at Midsomerham last, when seven candidates presented themselves, six of them being students at the Society's garden at Chiswick, and one from Battersea Park. Of the former, three took second class in fruit and vegetable culture, one a third, and two were unsuccessful.

At the examination in December last the number who presented themselves had risen to fifteen, and this shows the growing popularity of these examinations. In this case six of the candidates were Chiswick students, four were from Kew, and the remaining five from various gardens throughout the country. Of these, two (Chiswick students), took first class in fruit and vegetable culture, five took extra seconds, three seconds, three thirds, while the remaining two did not pass.

The marked improvement that the Chiswick students exhibit at the successive examinations shows that, as a school for horticulture, Chiswick supplies all the requirements necessary for that purpose; and the steady progress that the young men have made who entered the school when it was instituted is an evidence of the earnestness of purpose with which they are actuated, as well as a proof that the instruction communicated is of such a character as to enable the young man to take a high position in the gardening world.

I have to observe with pleasure that the great national establishment at Kew has sent up so large a proportion of the candidates at the last examination, and that the endeavour of the Society to establish a sound horticultural education is so well seconded by the authorities of that establishment. It is very desirable that not only in all public, but in all private establishments where young men show indications of ability and a desire to distinguish themselves, the heads will use their influence to induce the young men to prepare for these examinations, thereby affording them a stimulus which cannot fail to operate for their advantage. The establishments from which the other young men have come up are, the gardens of the Royal Botanic Society, Regent's Park; Battersea Park; Earl of Abercromby's, at Bridge Castle; Berham, Park, Newham; and Court Yard, Eltham, Kent.

EXTRACT FROM THE REPORT OF THE EXAMINER IN FLORICULTURE.

In the department of Floriculture the students have shown that they possess a very satisfactory amount of practical information. Their answers generally indicate an intelligent, and in some cases a thorough and intimate acquaintance with the subject propounded, especially if it be of a practical nature. Experience has shown that questions on practical subjects are more fully and clearly responded to than those which have a more scientific bearing. Thus, for example, it is found that a more complete answer will be given as to the mode of treating any particular plant or family than when the question relates to such points as an enumeration of the species or that particular family, or the popular features of difference between them. While it is thus gratifying to be able to report that these young men are acquiring a good practical knowledge of this branch of their profession, which will fit them hereafter to occupy situations where such knowledge would be called for and necessary, it is to be regretted that it would

be well for them also in their youth to master as far as possible the elements of theoretical horticulture.

2nd February, 1868.

Examined and found correct.

JOHN GIBSON, } Auditors.
ROBERT HUDSON, }

CUPRESSUS MACROCARPA AND OTHER CONIFERS.

I AM glad to be able to give Mr. Robson and your other readers a favourable account of *Cupressus macrocarpa*. There are two specimens of it here, one of which is 41 feet high, and in point of symmetry is all that could be desired. The frost of January, 1867, did not harm them in the least, while *Taxodium sempervirens*, 50 feet high, growing a few yards off, was much injured. *Cryptomeria japonica* at a short distance from

them was slightly injured, but has now recovered. *Pinus insignis* still exhibits a reddish brown tinge; but a fine specimen of *Thuja Lobbi*, 22 feet high (I have been told by nurserymen who have seen it that it is the finest they had ever met with), did not suffer in the least. *Araucaria imbricata*, 25 feet 8 inches high, growing on higher ground a little way off, had the bottom branches somewhat injured. *Picea pinsapo*, 19 feet high, and covering an area 39 feet in circumference, was unhurt; and on high ground and in a very exposed situation, *Wellingtonia gigantea*, 20 feet high, and with a stem measuring at the base 5 feet 8 inches in girth, was likewise uninjured. *Cupressus Lawsoniana*, 14 feet high, *Thuja borealis*, 12 feet high, *Picea nobilis*, and *P. Nordmanniana* were uninjured; and our *Retinospora pisifera aurea* and *R. lycopodioides* were injured at the points. *Thuja dolabrata variegata* was hurt a little.

The situation is considerably exposed to winds from the east and west, and more injury is done by wind than frost. Last week a fine *Cedrus deodara* had 2 feet of the leader broken off. I think *C. macrocarpa* is safe here, having withstood the winters of 1860-61 and 1866-67 uninjured. It is a beautiful tree, and succeeds well here. The soil is heavy, on a hard, red, marly subsoil.—J. G., *Garrison's Castle, Herefordshire*.

ARNOTT'S STOVE.

I THANK "R. F." for his practical review of my article on Arnott's stoves. Criticism and comment when prompted solely by a desire for increased information seldom fail in their object. With this motive ever in view, the pointing out the weak parts of a proposition is the soundest mode of adding strength to it, and if its weakness is so great that it cannot stand the test, the service rendered is equally useful. On a field of ice safety is best insured by breaking in the weak parts. In this case the issue is a sheet of iron instead of a sheet of ice.

When I sent the section and elevation (see page 28) of the stove, I had no idea that the Editors would have them engraved. I sent them merely for comparison with the written description of the stove, and was not quite so accurate in my drawings as I might have been. The section shows too much sand, and withal is not engraved in exact accordance with the drawing sent. The sheet-iron arch is moveable, and simply rests on the edge of the firebricks. A new piece of sheet iron has just been put in the stove. The old piece had been in use seven or eight years.

The stove in another viney is somewhat different from that just referred to. Inside, and 2 inches from the top of the sheet-iron case which encloses the stove, is a lip or flange, half an inch wide, on this rests a flat square of sheet iron, which may be termed a false top. This 2-inch space is filled with sand, and the cast-iron or top proper of the stove rests on the sand, fitting tightly over the top of the case. There is not the slightest escape of smoke here. The firebricks being only carried upwards 18 inches there remains about a foot of the sheet-iron casing which would be exposed to the action of the fire; but this is shielded by another piece, which is bent from just underneath the lip which supports the false top of the stove to the inner edge of the firebricks, simply enclosing so much air. This shield has not to my knowledge been replaced since the stove was put up twenty-five years ago. In less than five minutes after the stove is lighted, the upper part of it is quite hot, and, indeed, continues so long after the fire has gone out, from the naturally ascending heat from the firebricks being enclosed in the space between the outer case of the stove and the sheet-iron shield. Thus the heat from the outer wall and the top of the firebricks has no direct outlet to the chimney. This stove is only used to give sufficient heat to exclude frost in winter, to dispel damp, and to ripen the wood of the vines in autumn. The square of sheet iron on the top of the stove has not been replaced for at least fourteen years, and it is now sound. The greater or less perishability of the sheet iron exposed to the fire, doubtless, depends to a great extent on the quality of coke used as fuel. Here it is very good. In constructing a stove certain modifications may suggest themselves to those interested. The firebricks, or what are preferable, fire "logs," moulded about 2 inches in thickness, may be taken the entire height of the stove, and a square "log" put over the top. This stove is the same size, and the house in which it is placed is of the same dimensions as that figured in page 28. The stove also occupies the same position in the house, and is quite large enough for its work. To ripen Grapes in July, a larger stove would be preferable. It is easy to calculate proportions to any extent on the data given. The back wall

certainly not the best position against which to place a stove, so far as the equal and economical diffusion of heat is concerned.

Much depends on the construction of the house, as to where the stove is placed. To say that it answers well in a bad position, is to say that it would answer better in a good one. A long horizontal pipe must, however, be avoided, or the pernicious products of combustion will not escape freely. An important point to be attended to in construction, is to make the stove air-tight. No air should find its way to the fire except at will, and through the ventilator in the ashbox door. The ventilator then serves the purpose of a damper. For five or ten minutes after the fire is lighted, to insure quick ignition of the coke, the door is left quite open; there is then a corresponding escape of heat up the chimney. The coke once well alight, and the ventilator duly regulated, the bricks will absorb the heat, which is again extracted by the atmosphere of the house, and the pipe above the stove will gradually cool to a lower degree than the stove itself. The ventilator thus acts efficiently as a damper. My experience is the same in substance as "I. F.'s," and from what has been written there can be no difficulty in constructing a stove to act admirably and economically. I may add that economy was not necessarily the object of the proprietor in adopting this mode of heating. He had thought much on the subject, and saw his way clearly that it would answer. Prognostications of failure were made by gardeners and others, and in order to determine whether they or himself were right, the stoves were and are retained. Twenty-five-years trial has proved him right. The system has answered well.—J. W.

PEARS.

8. ADELE LANCELOT.—A seedling raised by M. Van Mons, but not brought out until after his decease. Not superior. Ripe in October and November.—(*Hogg's Fruit Manual*, 237.)

8. Adele Lancelot.

9. ADELE DE ST. DENIS.—Of good quality, and ripe from early in October until early in November.—(*Hogg's Fruit Manual*, 238.)

9. Adele de St. Denis.

10. AH! MON DIEU.—Its original name, *Belle fertile*, is appropriate and unobjectionable, and that now applied ought not to be tolerated. It is said to have been bestowed because Louis XIV., when he saw the superabundant crop it bore, ex-

10. Ah! Mon Dieu.

claimed, "Ah! mon Dieu." Ripe in September, but does not continue good longer than a fortnight.—(*Hogg's Fruit Manual*, 238.)

11. AMANDINE DE ROUEN.—Fruit medium-sized, $3\frac{1}{2}$ inches long, and $2\frac{1}{4}$ wide, pyriform, rounded towards the eye, and tapering towards the stalk. Skin at first of a bright green colour, dotted with grey, but changing to lemon colour as it ripens. Eye half open, with small, stout, often blunted segments, and placed on a level with the surface of the fruit.

11. Amandine de Rouen.

Stalk about an inch long, slender, woody, and firm, obliquely inserted on the apex of the fruit. Flesh fine-grained, very juicy, and melting, with a rich sugary flavour.

An excellent and rather richly-flavoured Pear, ripe in the end of September and beginning of October, but not superior to many in season at the same period.

It was raised by M. Boishunel, a nurseryman at Rouen, from seed sown in 1846, and the tree first fruited in 1857.

MISTLETOE ON THE OAK AND POPLAR.

PERMIT me to inform your correspondent, Mr. Robson, and your readers generally, that there is growing in the park here a large Oak tree, on the thick branches of which there are several pieces of the above-named parasite.

The tree in question had several limbs blown off about four months ago, on which were some pieces of Mistletoe. I also noticed some young shoots, apparently of one season's growth.

I may add that there are quantities of Mistletoe growing on old Hawthorn trees close by the Oak referred to; and although there are other Oak trees whose branches nearly touch that on which the Mistletoe is growing, I have failed to discover the parasite on any but the first-mentioned tree.—H. J. CLAYTON, *Hackwood Park, Basingstoke.*

[In the rectory house of Ashley, in Buckinghamshire, lives a rector, genial and pomological, qualities when combined rendering a man irresistible. The said rector tries many experiments, and among them on the Mistletoe. His details of some of the results are in the following extract from one of his letters to one also genial and fond of asking questions of Nature.]

"My Mistletoe is certainly a most extraordinary specimen.

There are fifty-three bunches, varying in size from 18 inches to 7 or 8 inches in diameter, and thirty-seven others about an inch, and half an inch long in their shoot, now starting in different points of the Poplar. The same answer you received from Professor Lindley, or one very like it, Professor Paulsen gave to me, when I mentioned to him the circumstance of the Mistletoe breaking out in so many places on the tree (they then numbered forty-six). He said, 'Oh, yes, deposited by birds.' I replied, 'No, Dr. Daubeny, had it been so I should not have troubled you on the subject.' The fact is, the young plants for the most part show themselves underneath the branches of the tree. No birds could place a seed there. I have never been in counties where the Mistletoe is very abundant. It may break out more or less on Thorns and Apple or Crab trees there. Some few years since, Mr. Adams, a clergyman in Warwickshire, sent to the *Times* a description of a Mistletoe growing on one of his Apple trees. He thought it wonderful that he could count some fourteen distinct plants. What would he say to my specimen?

"Directly opposite my Poplar, about 15 yards distant, is another plant growing on the same sort of Poplar. This is a male. The seed was rubbed on at the same time with the other. I mean the same day. The lower branches growing in the neighbourhood of this plant I cut off, and there is no branch within 4 or 5 feet of it. This bunch of Mistletoe, though of twenty-years growth, is not larger, or so large, as the finest plant on the other tree. The seed was rubbed on the north side of the tree. I rather think I rubbed two on. I certainly did this on my wonderful specimen tree, one seed east, the other west. I allowed the lateral branches of this tree to remain, and it is on these that the Mistletoe is playing such pranks.

"You will be glad to hear the tree is healthy, while the other one gives signs of decay. This may be owing to locality. It is closely surrounded by evergreen trees and shrubs, such as Firs, Arbor Vitæ, Portugal Laurel, &c. I keep the latter cut back so as not to conceal the Mistletoe growing upon the Poplar. On my grand tree there are male plants mingled with female; at least, there are those which produce no berries, and as they are of considerable dimensions, I conclude from their giving no fruit that they are male plants.

"It is somewhat curious that I have rubbed some hundreds of berries from my finest bunches on Thorns and Apple trees, but have failed in getting them to grow. I have succeeded only on three Whitethorns. Thousands of seeds have I given away, but still I only know of one instance in which a plant has appeared. Last year I rubbed seed in each month from January to April, and even May. I shall repeat the experiment again this year. Can there be any imperfection in the fruit, think you? I have a few fruit on a Thorn, I shall try these, as well as the fruit from the Poplar. In point of size there is no difference. Both are fine.

"You are wrong about the variety of Poplar on which my Mistletoe is growing. It is not the Ontario Poplar, but, as I think, though you did not when you saw it, *Populus tremula*, or certainly a variety of it."

PATERSON'S VICTORIA POTATO.

SUCH reports as that in the *Journal* last week cannot fail to be of great service and interest to every one who grows a Potato; and as "D." of Deal's account in one particular differs so much from my trial, I should like to know the circumstances under which the trial was made. Were the sorts grown in a close-walled garden with shading fruit trees? also what is the nature of the soil? I believe both these conditions have much to do with the crop and quality of Potatoes, and to give them a fair trial ought to be considered; and, if we are to gather any good from reports, these circumstances ought to be mentioned.

"D." of Deal, states that Paterson's Victoria "is the best of all Mr. Paterson's much-vaunted seedlings." I agree with him in this (excepting *Economist*, which I have not yet tried); but when he says "it is no great thing," I entirely differ. "D." of Deal, says "it is large"—quite true; "rampant in growth"—also true; and if grown in a close warm garden with shady trees, or on very heavy stiff soils, it is very rampant. "Prolific enough"—also true, every tuber keeping close at home (a considerable advantage), "but not mealy." I could wish "D." of Deal, were nearer the west of England; I would ask his acceptance of a dish, not caring whether they were cooked by a professional or a kitchen maid. I am positive he

would at once confess, that if the Victoria did not possess the good quality of being mealy in his own garden it obtains it somewhere, for a dish of mine is a sight fit for the most fastidious to see, and having seen, makes one long to taste, but having tasted—well, good-bye to the meat.

Now, is "D." of Deal's, opinion of this Potato borne out by others who have tried it in and around the neighbourhood of Deal? for any kind may not do well in one garden, and yet succeed well in the neighbourhood in general. Having a good opportunity to find out, I must say that the Victoria is not only liked, but very highly prized by hundreds who have tried it in Somerset, Dorset, and Wilts. I believe I could in these three counties procure samples from almost every parish, except North Wilts, equal in quality to my own, and from persons who would endorse my high opinion of it. My description of it is, it is large, a strong grower, very free from disease, exceedingly prolific, crops very close at home, keeps well, is very mealy, of finest flavour, and a first-rate sort for the garden or field.

I was going to say something about Prince of Wales Kidney, but enough at present. I took some trouble last season in testing the worth of some fourteen sorts; and if my report would be of any interest to the readers of the Journal I shall be happy to give it.—D., of SOMERSET, DORSET, AND WILTS.

[We shall be glad to receive your report.—EDS.]

PLANTS IN FLOWER DURING JANUARY.

NUNEHAM PARK ONION—VARIETIES OF BEET-ROOT.

THERE has been much said and written with respect to the Nuneham Park Onion, and, as is often the case, some speak well of it, whilst others are of a different opinion. Be this as it may, and whether it is identical with Trebons as some say, or with selected White Spanish as others affirm, or whether it is related to the Giant of Madeira, or whatever else they may assert, it is a fine Onion. The only fault I find with it is having too little seed for my money. I have no objection to sealed packets, but in this case I should like to see a little more in them.

We are having a move among the Beets, too. We have some fine kinds in the market now. So far as I am concerned, Dewar's has the preference; it is a fine-sized compact root. If we had it of a deep crimson instead of a crimson red, I should like it still better. I hope the stock will be selected and improved in colour. There are many more kinds of Beet that are really good, such as Nutting's Dwarf Red, Henderson's Pine Apple, Carter's St. Osyth, Covent Garden Improved, and Whyte's Black, which is the darkest Beet I have seen.

The following are a few plants I have noticed in bloom during January:—

Jan. 4. <i>Arabis albidia</i>	Jan. 20. <i>Cheiranthus</i> , German
<i>Erica ramentacea</i>	" 24. <i>Corylus avellana</i>
<i>Helleborus niger</i>	<i>Jasminum nudiflorum</i>
" 10. <i>Ulex europaeus</i>	<i>Omphalodes verna</i>
Daisy	Double White Primrose
Rose Fabvier	" 28. Rose, Crimson Chiffre
" 17. <i>Alyssum compactum</i>	<i>Viola odorata</i>
<i>Erica medeolifera</i>	<i>Erantthis hyemalis</i>
" 20. Rose Giant des Batailles	<i>Erica carnea</i>
<i>Viola minor</i>	<i>Galanthus nivalis</i>

—M. H., Acklam Hall, Middlebrough-on-Tees.

COVERING FOR ROSES.

PERHAPS I can render some assistance to "Q. Q." (page 109), as to the covering and uncovering Roses and other half-hardy trees and shrubs. Many persons, probably, are familiar with and able to make what is used to ornament stable floors in front of horses' stalls, in the shape of tailed-straw braiding. Well, during a wet day in the autumn, I and my man Friday set to work and made lengths of this, though not caring to throw the very perfection of art into our proceedings, but using, according to the thickness of protection which the trees might require, a layer of from three to twelve straws. For out-door protection wheat straw is preferable to oat or other softer descriptions of straw, as it does not absorb and retain moisture. My man grasps a layer, or weft of, say, a dozen straws, and to them I attach a piece of tarred cord around their centre, loop it on to the key-handle in the lock of the door, or to a hook in the wall, and bend part of the right-hand half of the straws upwards, and part of the left half of the straws to the latter. Now, a fresh feed of straw is brought and laid centrally,

having the ears to the right, and the remainder of the first weft of straw is brought over the second weft, and then the top remainder over it, and another weft immediately banded by my man to continue the woof of braid, thus forming a tail from every weft, remaining out obliquely from the centre of the braiding, and so on. Without assistance the operation can be performed by one person by previously placing the wefts of straw to the right hand of the worker. It is well also in the latter case not to form the braiding much longer than 2 yards for each piece, and to finish off at the ends by tying with about 1½ foot of tarred cord. Thus proceed with both thick and thin braids, and stow them away in a dry place till wanted, which they will be in the beginning of November. Then prepare to put them on by collecting the branches of the trees or shrubs requiring protection into loose cones, to be first secured in this shape by tarred cord, and attach a thin braid at the bottom of—say a Fig tree, and wind it around and obliquely upwards, and tie again at the apex of the tree with the piece of tarred cord which is attached to it. Next, wind a thick braid of straw similarly over the thin one, and then you have a dry, perfectly frost-resisting protection, and a very respectable-looking thatch, placed there without litter and with all the ease imaginable, and if the operator lives in the outside edges of all the cyclones, as we appear to do here, a lashing around of tarred cord will make all quite secure.

When the danger from winter frosts is over, unwind the thick braid from the tree, and there remains the thin one for all the air to circulate through, and yet sufficient to ward off the spring frosts without weakening the young growing shoots. Store the braids away in a dry place, and they will last for years.

As wheat straw is expensive and difficult to procure in this place, I take care to harvest my Pea and Asparagus haulm. The former is stored in large long bundles, which I sever across with a large sharp knife, and then form it into coarse braiding after the manner specified above, and during periods of sharp frosts I place these braids along the tops, on each side of my orchard-house pot trees, and take the tails of the braiding down by their sides: a few pieces of string and a packing needle secure the braids together upon the surface of the soil, and the roots never become frozen. The braids are quickly placed and taken away without litter, and the Asparagus haulm during severe frosts takes its light, dry, and airy position amongst the branches in my orchard house, without injury and with perfect protection to the blossom.—UPWARDS AND ONWARDS.

INJUDICIOUS COMPLICATED COMPOSTS.

IN times long gone by, when the mysteries of our calling were held in high estimation by those who assumed to possess them, an acquaintance with the exact proportions of the ingredients necessary to form a compost favourable to the growth of a particular plant was considered by no means the least important. Receipts for the mixing of the proper soils for the growth of the Carnation, Ranunculus, Tulip, and other plants, were regarded much in the same light as a druggist's knowledge of compounding liquid and solid medicines for the benefit of mankind. Fortunately the day for such secrets is gone by, so far as the gardener is concerned; it is well that it is so, for at the present day we can afford to lose some of the secrets which those of the past age refused to bequeath to us. In this way it is said we have lost a compost for growing Auriculas, which was known to one eminent grower, and of which nothing further is known than that it consisted of nineteen different substances. Perhaps it is as well that the secret did die with him. Other secrets have existed concerning various classes of plants, but occasionally the possessors were much disappointed on finding that greater success was achieved by those not initiated, or who adopted other means. All that is really worth knowing respecting the cultivation of most plants and fruits is made known from time to time, and although now and then mixtures more or less complex may be met with, these and other matters have been very much simplified.

Although the mixing on the day it is to be used of a mass of materials for the growth of a particular plant, is now generally abandoned, the practice still exists in many cases, but its propriety is doubtful. An appeal to Nature would certainly appear to condemn all mixtures but what she had made herself; and although it would not be judicious to entirely abandon the practice of mixing together two substances differing chemically as well as mechanically from each other, in order to form a

useful whole, can we hope to balance the materials so nicely as they are when the mixture is effected by natural agencies? Take, for instance, our best examples of peat or alluvial soils; both are in a condition more favourable to the growth of certain plants than any ordinary mixture artificially prepared. We ought, therefore, to pause before we attempt to blend into one mass substances incompatible with the effect desired to be attained. That great results sometimes are attained by artificial compounds, there can be no question, but are we certain that such results are to be permanent? Most likely not. Nature alone stands pre-eminent for the durability of her works, and be assured the nearer we can approach her in copying her works, the greater the success will be; and in no instance, perhaps, is this more apparent than in the mixing of soils, and their failures after a period of years.

As an exemplification of what is meant by the above, let the reader refer to a paper on Vine borders, by Mr. D. Thomson, which recently appeared in the Journal, and it will be seen that Mr. Thomson formed his borders entirely of the ordinary soil of the garden, and the results are such as any one might be proud of. In like manner other Vine borders have been formed out of unmixed soils, or rather of soils already prepared by Nature for the purpose. Contrast this with such mixtures as are too often formed on the potting bench. A mixture of peat and loam is recommended, but the latter varies more, perhaps, than any soil. Many loams contain a large amount of chalk or lime, and though eminently fertile, and rich in the substances necessary for the growth of a large number of plants, are, nevertheless, unfit to mix with peat with advantage. Perhaps, too, a siliceous sand may be used as a mixture with both, and this is more frequently done than it ought to be. Possibly when our knowledge of chemistry shall be farther advanced, the impropriety of mixing certain substances will be better understood. It is, however, certain, that at the present time composts are too often thoughtlessly made up, and with a total disregard to those natural laws which cannot be violated with impunity. It would be well to bear in mind that when we can use a material already prepared to our hand, it is not advisable to tamper with it by any addition, and when, as for instance, in the case of a Vine border, it is expected to last a good many years, it would be advisable to have it of a porous nature, so as to receive enrichment by liquid or solid substances, without getting into a stiff, sour condition. Some of the very best borders receive very little assistance indeed, and in their formation a material mixed by Nature centuries ago, forms the basis. By-and-by we may get to adopt the same practice on the potting bench.—JOHN ROWSON.

MANY THINGS AND LITTLE ABOUT THEM

Touches of practice make the whole world keen. We have heard something lately about the "perpetuity" and "non-perpetuity" of fibrils; also about cordons, their forms and nomenclature. I am glad of it, because the correspondence must tend towards progress. I have enjoyed the "chaffing," although it was occasionally slightly flavoured with gall. I remember poor Beaton's remark the last time I spoke to him on his way from a Committee Meeting, South Kensington, the last time, I believe, he ever attended there. In the course of our conversation I felt he was sore at heart, and he said, "They say my writings are all chaff." I placed my hand upon his shoulder, and replied, "They say your writings are all chaff, do they? Well, your writings enliven us, and I am very thankful to you for it; but besides all that, you may depend upon it, amongst your chaff there can be found a measureful, and running over, of uncommonly good sound wheat." My answer sent my good old friend on his way rejoicing.

Now, among recent contests was one about root fibrils. I know Hardwicke Hall, near Bury St. Edmunds, and I am known to the writer who so often instructs us from thence. I saw some young cordons in a border at those gardens a few months ago, and the fibrils were then alive, and fulfilling their transitory offices unharmed by delvings, which brings me to a point. Probably you are aware of my success in fruiting orchard-house trees in pots. I have from the beginning adopted Mr. Rivers's advice (plus syringing my trees with heated sewage), as given in the successive editions of his work, "The Orchard House," as well as by going and taking hints with my own eyes at Sawbridgeworth. Now, contrary to his usual practice, some are advocating surface-dressing in the spring, *or* "top-dressing" in the autumn. I have determined to try the

result of surface-dressing, and did not "top-dress" my pot trees last November. The buds are now becoming plump, and are very satisfactory in number, and it is time for me to think about watering the soil in the pots. So after what Mr. Fish and Mr. Rivers have lately written, I thought it might prove interesting if I sent you some examples of what the fibrils and young roots are now in reality, as a touch of practice and as proving the "non-perpetuity" of the fibrils plainly enough. The inference I am at present able to draw is this: the fibrils of my pot plants being as dead as so much cocoa-nut fibre, and the young roots just pushing out fresh tiny spongyoles—fibrils in nonage—would not fresh compost applied in November prove better for them than the soil wherein the dead fibrils have been revelling, exhausting it of its properties, during the last year? We shall see, but you may feel certain that I shall not neglect surface-dressing under these circumstances.

Every tree and bush in this garden is, and has been for years, made to undergo the pinching, or cordon plan in shapes most questionable, and I could refer to many to inform you whether they considered any Frenchman, who cultivates his soil, would be likely to produce more or better flavoured fruit from a given space. If he could, then so much the better for France. Here the females of the household have taken to do all the pinching part of the business within their reach, as a pleasant recreation. It is highly satisfactory besides, for they are so led to take more interest in garden matters, and the trees always look clean and neat. Nothing contends against the aphid tribe more effectually than the constant deprivation of the points of the young succulent laterals.

It was curious to hear the plan so much talked about, as if it were something new, when I was in London. The cordon system and Mr. Standish's new Royal Ascot Grape—and what a capital Grape it is!—were the decided horticultural lions.

I have yet another subject, of which I am fain now to unburthen my mind. At the Royal Horticultural Society's Show, at Bury St. Edmunds, last July, there were three cups not competed for—viz., the Ladies' of Bury first and second-prize silver cups for Orchids, and the Town of Bury silver cup for Ferns. It was at my tongue's end at the time to beg of the subscribers and the authorities to consider whether those cups could not be given to others, worthy exhibitors, in connection with the then Show, and I now ask whether cups or medals not competed for at the great shows of the Royal Horticultural Society in the provinces, could not in good faith be awarded to those who are worthily competing in other classes.—UPWARDS AND ONWARDS

WORK FOR THE WEEK

KITCHEN GARDEN.

Cabbages, where there are not plenty of autumn-sown ones, sow some seed on the warmest border you have, or in a Radish frame. *Celery* and *Cauliflowers*, sow on a slight hotbed, the latter to succeed those sown in the autumn. A pot of Celery may be put into the Cucumber frame, as but a small quantity of seed will be required to be sown thus early, if fine heads are expected in September. *Carrots*, the ground intended for them should be well turned over and pulverised before sowing. *Cucumbers*, sow seeds or procure a few plants from those who force early. The temperature should range from 65° to 75°, allowing 5° more for sun heat. *Potatoes*, plant in a frame, and forward tubers by putting them in any warm place for planting under straw covers and hurdles. *Peas*, a sowing of these and also *Broad Beans* should be made during the present favourable weather. *Radishes* and other salads, with Cauliflower plants, must be looked over occasionally, to see that no failure occur from damp or vermin.

FRUIT GARDEN.

The Apricot and Peach trees have received a most reasonable check without sustaining any injury. No time should be lost in having them pruned and nailed. Look out what netting, canvas, or bunting you have to protect them with by-and-by, and if you are short of these materials, have spruce boughs or fern ready in case they should be wanted. These trees seem in a ripe and healthy state this season, and if wet weather do not occur at the time they are in blossom, a few degrees of frost will do them little injury. Where there are inferior sorts of Apples and Pears, or too many of one sort, procure scions of superior varieties, and keep them in a cool situation till wanted. Strawberries in succession will be brought into frames and houses according to the means at command. The whole stock for forcing this season should be looked over and placed

in some litter at the foot of the houses or south walls, if they have not indeed been there all the winter.

FLOWER GARDEN.

As soon as the ground is a little dried it will be a good plan to fork over all the vacant beds in the flower garden, so as to have the soil properly pulverised prior to planting out the autumn-sown annuals. Preparation must also be made for a general sowing of the more hardy kinds, such as Larkspurs, Godetias, Clarkias, Nemophilas, &c., which should be made on the first day the ground is sufficiently dry to admit of sowing them. Proceed with the pruning of shrubs and common Roses, but leave the more tender kinds until you are sure they will not be injured by frost. Proceed with planting out biennials, and prepare a little ground in a warm corner for sowing Stocks and some of the best of the annuals for transplanting. As a matter of course, all floricultural calendars must, to a certain extent, be acted on only as the weather is favourable for the operations therein detailed as necessary. During spring and summer the experienced florist finds it comparatively easy to point out in the previous week what is requisite to be done the ensuing week; but at this uncertain season we must be guided by circumstances. If the weather continues mild draw the lights completely off the Auricula frames during the day, examine the plants minutely, and see that all is going on well; should any mild rains fall during the week they will be benefited in the middle of the day. When the lights are drawn out, tilt them, so that the grass may become as dry as possible before night. Still cover Tulips with sand as they appear. If the beds for Ranunculuses are sufficiently dry, they should be immediately planted.

GREENHOUSE AND CONSERVATORY.

Orange trees if now removed to an early vinery or stove and kept in-doors all summer, will come into flower next Christmas with very little forcing. Camellias that have not formed flower buds may also be introduced in succession from this time. Some of them may be expected to flower about the end of next September. Plants of *Fuchsia corymbiflora*, if cut back last autumn and preserved through the winter, will flower in May if they are removed to a forcing house. The night temperature of the conservatory should now be lower than through the winter, say about 40°, in order that the plants may be started slowly at first. This should be attended to by all who regard the proper cultivation of their plants. There is nothing more injurious to the blooms in this house than currents of cold damp air. The Camellias are the first to indicate this. When forced hardy bulbs are done flowering, cut off their flower stems, remove the bulbs to the reserve pit, turn them out of their pots, plunge them in a light moist compost, and protect them in cold weather. In the greenhouse, if you guard against frost there is no danger of the temperature of this house falling too low, and air should be admitted on any fine day in order to keep the plants from growing too rapidly at this season. Owing to a drier atmosphere being thus produced, the plants will require constant attention with regard to watering.

STOVE.

Many plants will be soon fit for repotting; and fresh labeling, tying, and training pot plants and climbers will require attention for some time.

FORCING PIT.

That variety of the common Lilac, called Charles X., is the best of them for forcing, as it retains its high colour better than the old purple Lilac. The following plants may be obtained now from this structure:—*Azalea indica* alba and varieties, *Rhodora canadensis*, *Acacia armata*, *Calla aethiopica*; *Pelargonium Album multiflorum*, Admiral Napier, General Washington, Ne Plus Ultra, and some Scarlet varieties; Tulips, several early varieties; Narcissuses, Soliel d'Or and double Roman being the earliest; Hyacinths, Jonquils, Crocuses, Lily of the Valley, Violets; Roses, Fairy, Chinese, Tea-scented, Bourbons, and Hybrid Perpetuals. Fabvier, a Chinese Rose, is one of the best for bouquets at this early period.

PITS AND FRAMES.

Here there will be no want of work for the next three months. Some of the Stocks and other annuals sown some weeks back will require potting-off, putting three or four plants in a pot. Pot-off Verbenas, and put in cuttings of kinds of which you have not enough. Divide and make root-cuttings of *Bouvardia triphylla* and *angustifolia*, and get the plants forward and strong for planting out. Put *Salvia patens* into heat to produce cuttings, and see that everything is in order for the spring,

which will soon arrive. After such a comparatively mild winter, the plants here are not in a condition to be shut up closely during damp or rainy weather. All you can do is to give air at the top and bottom of the sashes. If any amateur wishes to try experiments in inarching Camellias, this is a good time to remove his stocks into gentle heat to set the sap in motion before the operation is begun. It is also now a good time to graft little Orange trees for forcing and blooming in the drawing-room or conservatory. The growth of the young stocks for this purpose ought to be pushed in advance of the seasons by a gentle heat. A few Wallflower seeds might now be sown to raise plants for forcing next winter, for which purpose they are well adapted, as they may be had in flower from Christmas until they bloom in the open ground. Another good forcing plant is the *Philadelphus coronarius*, or Mock Orange, which forces as well as the Deutzias.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Sowed a lot of Peas on banks, covering them with a little fine soil, and then strewing the ground thinly with ashes as a preventive, and covered with a width of wire netting to each row, as without that we should expect few seeds to be left after being sown forty-eight hours. This season in sowing we have resorted to a plan we adopted with advantage many years ago. Instead of one shallow trench for Peas, we drew one on each side of the line, so that these two rows would be about 6 inches apart, and sowed the Peas in both, but more thinly than if one row were used. We thought long ago that with the same quantity of seed the gatherings were thus larger, as the seeds had individually more room, and the staking was the same. Were it not for the enemies that attack Peas at this season before they appear above ground, and afterwards before they can yield their produce, we would sow much thinner than we do, or is generally done. When the seeds and the young plants could be secured, we have gathered heavier crops from a row with the seeds 2 inches apart, than when three or four seeds occupied that space. We use the thicker sowing to meet casualties; not because we consider it to be the best in other respects. When we hear from some gardeners, we cannot help thinking they are so far fortunate whose work chiefly consists in sowing, planting, and gathering. In how many other places have these operations and the due preparation of the soil become of less importance than taking means to protect from many enemies which now find a comfortable home about the garden?

Beans.—Sowed a piece; and we mention this chiefly that those with small gardens may be induced to try the Royal Dwarf Fan or Cluster. A heavy crop of small delicious Beans may be gathered from rows only 14 or 15 inches apart. The Dwarf Green Gem is also a sweet Bean when used young, as it ought to be, and occupies less room than the Mazagan Bean, also valuable for its earliness. We like to see the fine individual seeds of the Windsors, and the noble pods of the Wonderful and the Monarch of the Longpod race, but the produce is not in proportion to the great size of the pods. These huge Longpods when little more than half grown, green, and brittle, and the beans inside not half their full size, make a rich dish when boiled and used in the pods, just as Kidney Beans are treated.

Cauliflowers.—Stirred-up the soil under glasses, and top-dressed a little. Notwithstanding the severe frosts, owing to the dustings of snow, a number of rather large plants have stood on a bank uninjured, and did they go on, would come in before those under hand-lights. We fear, however, that some check will cause them to button prematurely, and then they will be worth little or nothing. We have still a good supply for use from the plants raised in the end of October and protected in an earth pit.

Celery has stood well, but we protected with litter in the coldest weather, and removed it when the weather was fine. When Celery is grown in beds, a little long litter or dry clean straw put on before a heavy snow, is also an advantage, as, if the snow lies long, and there are changes of thaw and frost before the snow disappears, the weight is rather much for the Celery, and the leaves are broken, and the moisture finds its way more readily to the heart of the plant. The slight covering of litter equalises the weight of the snow, and when removed there is little breakage of the leaves. When such leaves are much frozen without any protection, the exposed part de-

cays, and the decay extends downwards until the eatable part is injured or lessened in bulk.

We will not sow much in the open air for several weeks, except Parsnips, which we will sow in a week or so if the ground is in good order. This is much harder than most of the roots we cultivate, and is always the better of being a long time in the soil. We have had fine crops, however, that were sown at the end of March. We will turn over and re-turn our heavy land on all favourable opportunities.

For Sea-kale, Rhubarb, Asparagus, and Cucumbers, see previous notices. Turned over ground intended for Carrots and Potatoes. Prepared for planting the latter under shelter or protection, and sowed Radishes, Horn Carrots, and Lettuces in a bed under glass. Radishes sown late in autumn and protected in winter are becoming rather hard now. Just like late Turnips, their tendency now is to throw up a flower stem, and after that the roots lose their crispness and sweetness. As to hotbeds we would have done more, but a press of other matter, as planting trees and shrubs, has prevented our collecting leaves on which we much depended, and in cold places it is scarcely possible to obtain early crops of some vegetables without a little bottom heat beneath them. In warm places with borders of dark-coloured light soil well exposed to the sun, crops may be had nearly as soon as those helped with a slight heat beneath them in colder places. Potatoes will produce much earlier on warm borders, such as those referred to, if the tubers have been placed in small pots, or thinly in shallow boxes, with rough leaf mould and soil about them, and sprung strong for a couple of inches before planting with all the roots. In doing this place a little warm soil round the roots, and choose a warm sunny day for the operation. In all such planting it is important that neither the roots nor the tops should receive any check, or as little as possible. The plants, therefore, should be well hardened before planting, and a suitable time as respects the weather chosen for the operation.

The principle of avoiding checks is one of those simple matters which are not yet sufficiently considered. With Cucumbers and Melons at this season, it often makes all the difference between success and the want of success, between the pleasure of looking on clean healthy plants, and the pain of seeing them the prey of insects uncountable. Growing such tender subjects in houses heated by hot water, however good in itself, is apt to lessen the care in this matter. When all the operations of shifting, planting, &c., can be done inside, there is less need for extra care, and in process of time less care will be manifested. We have seen Melon plants left for an hour in a cold shed in March, a proceeding which would have horrified one of the particular old gardeners. He would as soon have gone out in a frosty night without clothing. They succeeded with their frames and pits so as to be little behind those with the improved appliances now, but the care they took in shifting and training, so as to give no checks, would be a good lesson to the moderns. We have helped to pot and arrange many Cucumber plants in frames, when it would have been impossible without injury to have carried them even into a close shed, but a man attended, covering us and the open space of glass with double mats, so that no keen draught should reach the plants before it was heated by passing through the moister and warmer air. Air-giving was also a matter of more consideration, than in the slap-dash routine often seen at the present day. Except in the dead of winter, when the hot water heats the dung, unless there is almost an unlimited quantity to fall back upon, we like to see even now the common frame heat the hot water; and where there is enough of material it will often do so with moderately early Cucumbers and Melons.

FRUIT GARDEN.

Pruned in favourable weather, and as, after settling a good many bullfinches which have come in wonderful force this season, the fruit buds of Pears were disappearing, we washed a number of hush pyramids over with lime, clay, and a little soot, not enough to take off the whitish appearance when dry. We like lime very well by itself, as the white appearance is a great annoyance to the birds. A little soot makes the buds more unpalatable. We have seen no tomtits of late, but two months ago they visited us in flocks. We fastened on the trees some parings of meat slit up the middle, had arsenic placed between, sandwich-fashion, and though but little of it was eaten, and we found no dead birds, we have seen none of them since. We never can be sure, however, as the tomtits generally come in flocks. We have often noticed that, though one will not be seen for months, some day we have the pleasure of seeing them on almost every tree. When the bloom is

set we let them do as they like; we would not even begrudge their nibbling a few of the best fruit, if they would only let the buds alone. Last year we put some boughs over an early Pear full of buds, and next day there was nothing but the remains of the buds below the tree.

The Vine border which we covered having yielded a gentle heat which it was a pity to lose, we made a wall from the material, back and front, about 10 inches in height, on that laid a rail flat, and on the rails put some old sashes, and then filled the space beneath with fresh-potted Scarlet Pelargoniums. It was in a similar place the plants did so well last year in pieces of turf reversed, about 3 inches square, with a hole scooped out in the centre, and the roots put in along with some light rich soil. These were planted turf and all. In such a case the plants should be moved, and placed on a hard bottom when the roots have extended an inch beyond the turf.

Cut the Grapes in the late viney as we wanted the room very much, and when thoroughly cleaned, as respects glass, woodwork, Vines, &c., it will be filled with plants, that other places where more heat is now wanted may be freed. Grapes keep longer on the Vines than by any other plan, though they may be kept a considerable time with the wood stuck in beetroot, and suspended in a place neither damp nor too airy; but in most places where every inch of glass has to be made the most of, it will not do to keep a house comparatively empty for a few bunches of Grapes. A week or so ago we cut the last Grapes from the forward orchard house.

Peach house.—We mention here one simple fact for the benefit of beginners, who become nonplussed with the directions about giving plenty of air, &c. The trees being in bloom, of course air was very essential, but during cold frosty days we gave only a little very early, and that kept the temperature from rising much, or suddenly, and we did not give more unless the thermometer rose to about 75° or 80°, but let the heating apparatus become cooler instead. In the late terribly boisterous days we gave no air at all, as plenty would find its way in at the laps, and gave no more heat than was merely sufficient to keep the house at a temperature of 50°, or a little more, when there were a few gleams of sunshine. Obtaining early Peaches economically in a great measure depends on using as little fire heat as possible, and taking advantage of the cheaper and better sun heat. Thus the fire heat at night may average from 45° to a little over 50°, and in dull, sunless days may rise to from 50° to 55°, and even to nearly 60°; but when there is the prospect of a sunny day, it is best to dispense with fire heat, and give a little air early, so that the temperature shall rise gradually, but not greatly to increase the air until the temperature rises above 75°. Provided there is air regularly on, a temperature at midday from sun heat almost alone of from 75° to 80°, will in every way be much better for the plants than a temperature of 60° at night from fire heat. The great point is to give heat in proportion to sun light. Sun heat with air on, however small the quantity, to prevent the accumulation of confined vapour, will never draw or weaken plants if kept at all moderate.

Amateurs tell us that they are puzzled because they see good crops of Peaches obtained by the following plan: The house is shut up late in the afternoon, good fires are put on, and at bedtime the temperature is 60°, and higher before morning. Next day, if dull, fire is kept on to maintain the heat, with air given, and if the day is sunny the house is nearly half open, so great is the quantity of air given. Well, we know such a plan often answers, and amateurs must adopt it if so determined. To our mind the great quantity of air in a sunny day is necessary to counteract the mere extension produced by a high temperature at night, not to speak of the inroads of insects thus encouraged. We merely wish to show that by a more natural system they may save their coal heap, take advantage of sun heat, and secure longer-continued health to their plants with less labour and expense.

We would just advert to two principles in early forcing, where no great heat, as in the case of Peaches, is required, but which have several times been alluded to. First, avoid allowing a strong heat from fuel and a bright sun heat to occur at the same time. Second, be more particular that air shall be always given, however sparingly, early in the morning, than about the mere quantity admitted. These points are chiefly important to amateurs who must leave their pet houses for many hours during the day, as by breakfast time they can calculate with tolerable correctness what the character of the day will be. When we first managed houses on our own account we went regularly out to attend to them every Sunday forenoon, and we

never had a single mischance from overheating, or too little or too much air on these occasions. Just let cultivators watch how gradually the thermometer mounts in a house when air is given early, and how gradually it falls if the sun should be clouded when there are only a few inches of air-opening.

ORNAMENTAL DEPARTMENT.

Besides planting in pleasure grounds, &c., heavy work with planting for cover and timber has been going on. This would have been better done in November, but the time has not come when it is possible to do everything at the right period. A few remarks may be useful for those engaged in or contemplating such work.

1. Unless where very large plantations are to be made, it will always be more economical to purchase trees than to rear them at home, because those whose chief work is to attend to them, will do it better than those who have much and various other work to do.

2. Where much is to be done in succeeding years, and trees are to be brought from a distance, the best plan is to obtain the trees young, plant and grow them in rows for a year or two, and then plant them as wanted, by this means insuring that the trees shall not be long out of the ground; or the latter should be mulched, and the roots properly secured from drying. It is a great drawback when the roots are as much dried in the air as the branches are. Then, of course, every fibre is destroyed.

3. When small young trees are used, and the roots are small, planting by merely making a double slit with the spade, slipping the roots in and treading firmly, will be the most economical method; but when the roots are good and the trees from 3 to 4 or more feet in height, it will be the best plan to make holes from 12 to 15 and 18 inches square, according to the size of the roots.

One great advantage in taking trees up at home, even when obtained young from a nursery, is that the roots can be somewhat cared for. We have seen good-sized holes made for trees 4 or 5 feet or more in height, and for all the roots they had they might have been inserted by slit as well as by holes.

4. Whatever arrangements may be made for preparing the ground and making holes, unless there is a sharp overlooker constantly present, we would not be inclined to make a piece job of the planting, as the object of the hole being made is to give justice to the roots, that these may be spread out, and the best soil placed immediately about them, and, whilst firmly secured, that the stem of the tree should be scarcely lower in the ground than it stood before being raised by transplanting. When the work is paid for by the number of trees put in, there is a temptation to let the roots be buddled together, and to bury the stem considerably above the collar, as thus the tree is more securely and easily fixed in the ground, something in post fashion. If the collar of many plants is much buried—that is, the point whence roots descend and a stem ascends, it often proves a great drawback, if not ruinous.

5. For profitable planting, quick growth, and quick returns, the old rule holds good, "Plant thick and thin quick," but in doing so the permanent trees need not be too close together, nor yet when perching is required, and for that nothing is better than the Spruce for concealment from the sharp eyes of marauders. This, either at first or by suitable thinning, should be so treated as to allow the lower branches healthily to cover the ground; and therefore undergrowth, as Privet, Bramble, Hornbeam, &c., would be of no use near them.

6. Where game, especially rabbits and hares, abounds, it is mere waste of money to plant to any extent, unless the animals are kept out until the plantation is established. It is of little use to talk of keeping them down. The only effectual plan is to keep them out, and the most economical plan we know is to surround the whole with wire netting, and keep it round the plantation for several years. Daubing the trees with nasty washes will be some preventive, but not thoroughly deterrent. Wire netting kept upright by firm sticks, and an inch or two in the ground, as lately recommended, will keep them out, unless when blocked with snow, and then the place must be hunted.

For small plantations and particular trees, we have seen nothing so effectual as a small handful of wheat straw put round the stem close to the ground, brought upwards the length of the straw, and fastened round with two or three small bands of the same. A small ball of cord would do some hundreds of trees in the hands of those not accustomed to binding with straw. The plan is none of ours, but that of a young gentleman greatly interested in planting, and all we can say is, that the Oaks thus treated are growing well, and though the places

are swarming with rabbits and a good many hares, not a tree thus treated has been touched; no attempt has been made to go through the thin layer of straw, and in most cases the straw seems as likely to remain as when it was put on three years ago. What is rather singular, we have not noticed that even mice have touched them, though they have barked Lantanas and other trees near them. In the case of a few hundred Oaks, they may thus be quickly, and so far as we can judge from three years' observation, effectually secured; but in all cases where many acres are to be planted, and four-footed enemies to the young trees abound, we know of nothing alike so economical and efficient for protection as wire netting, about 2 inches to the mesh, and less if small young rabbits abound.—R. F.

COVENT GARDEN MARKET.—FEBRUARY 12.

In consequence of the fine open weather we are well supplied with both home-grown and foreign produce, and there is very little variation in prices. Excellent Broccoli continues to come from Cornwall and the Channel Islands.

TRADE CATALOGUES RECEIVED.

E. G. Henderson & Son, Wellington Road, St. John's Wood.—*Catalogue of Flower, Vegetable, and Agricultural Seeds.*

W. Rollisson & Sons, Tooting, London, S.—*Catalogue of Floricultural and Culinary Seeds, Sub-Tropical Plants, &c.—List of New Roses for 1868.*

W. Hooper, New Wandsworth, London, S.W.—*List of Vegetable, Flower, and Agricultural Seeds.*

T. Sampson, Preston Road and Houndstone, Yeovil, Somerset.—*Catalogue of Vegetable, Flower, and Agricultural Seeds.*

W. B. Jeffries, Ipswich.—*The Useful Garden Guide, being a Catalogue of Stove, Greenhouse, and Hardy Plants, Trees, Shrubs, Flower and Vegetable Seeds, &c.*

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix upon the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

Books (*Eucanas Ayres*).—The "Garden Manual." You can have it free by post from our office if you send twenty postage stamps with your address. (R. S. S.).—Kearse's "In-door Gardening" and "Out-door Gardening," post free from our office for 1s. 8d. each.

PRUNING ROSES (J. C. R.).—When roses are worked on a Briar stock the shoots must be cut hard, say, to two, three, or four eyes. This applies to them whether they are for pots, walls, or standards. If they are on the Manetti stock, as a rule not absolute, cut the shoots but little—say, to one-third their height or even less, according to the character of the wood. If the Manetti plants are highly cultivated they will break from the base and all over abundantly without the necessity of cutting them hard at planting time. If they are cut hard at the head, they must be cut very hard at the roots. This observation applies to all trees.—W. F. RADCLIFFE.

PRUNING NEWLY-PLANTED HYBRID PERPETUAL ROSES (J. H.).—“Merely thin out small useless wood, shorten the main stems to the first good eye on firm wood, and cut in the side wood a little to a good eye—in short, when you plant, and ever afterwards, prune them as if they were Hybrid Chinese roses.”—W. F. RADCLIFFE.

MANURE FOR ROSES. PRUNING MARSHAL NIEL (St. Denis).—“Night soil when fresh is a dinner unless the uric acid in it is destroyed. You must mix it with ether 1 oz. if used at once. A small quantity of the mixture would be sufficient. I should mix it with earth, turn it once or twice, and put it on next November. Cut the Marshal Niel Rose slightly. You may leave 12 inches, or all the wood if you like. Tea-scented Noisettes require but little pruning. I am uncovering mine here, and shall prune them at once.”—W. F. RADCLIFFE.

SHREWSBURY'S GAS-BURNING APPARATUS (R. H. F.).—You had better write to Mr. Shrewsbury, stating what you want. You will see his advertisement in the Journal.

WHITE FLY (E. F.).—This is a very active insect, and not easily destroyed by fumigation; but that is the only means we know of keeping it in check. In fumigation with tobacco smoke, the insect, after the first few puffs of smoke, flies to the ground, where it lies comparatively out of harm's way, and after the house is clear of smoke it is not active as ever. Previous to fumigation the floors and other surfaces should be made quite wet, but avoid wetting the foliage of the plants. The house should then be filled with tobacco smoke, which will destroy all it reaches; but as the insect multiplies very fast, the fumigation should be repeated two or three times, and again whenever one is seen. If the insect do not yield to a second fumigation the plants may be dipped in a solution of 4 ozs. of soft soap to two gallons of water, to which has been added one pint of tobacco juice.

POTTING CALADIUMS (D. R.).—In potting, one or more rhizomes may be put in a pot according to the size of the pot and of the rhizomes. One large rhizome is sufficient for a pot of moderate size. Of the smaller sorts three or more rhizomes will be required to make a good potful.

COMPOST FOR ORCHIDS (Idem).—Most Orchids succeed in a compost of equal parts of chopped sphagnum and fibrous brown peat torn in pieces with the hand, but not in the very small, with the addition of about one-fourth part of lumps of charcoal from the size of a hazel nut up to that of a hen's egg, and a little silver sand. The pots should be half filled with coir, and the compost raised high above the rims. The compost for Orchids in baskets should be well rounded, and made rather high, but not so much as for pots.

PROPAGATING LOBELIAS (Idem).—A stove will answer well for propagating Lobelias if they are kept moist and shrouded from bright sun. When pricked-off they should be continued in heat until established, and may then be moved to a greenhouse, and hardened well off in a cold frame before being planted out.

CINERARIA CULTURE (Broughton).—Cinerarias may be had in bloom in January by potting-off the offsets early in summer and growing them for that purpose. Plants from seed grow more freely than those from cuttings or offsets, and are best for early flowering. One offset or plant from seed should be grown in a pot. By stopping, dwarfier and bushier plants are produced. The sorts now grown are superior in every respect to those grown some years ago, being dwarfier and larger in flower, and better-colored. Cinerarias bloom best in March and April.

CAMELLIA CULTURE (Idem).—In a house where no more heat is given than is sufficient to exclude frost Camellias bloom from February to April inclusive. Young plants bloom quite as well as old plants, but being smaller have fewer flowers, but these are equally fine. Plants infested with scale may, with superior cultivation, be expected to recover and bloom well, but we cannot say whether they will do so in a year or not, but it is probable. Camellias, instead of being improved by being placed out of doors in summer, are in most cases thereby injured. To name early and late-blooming sorts would be useless, as they vary so much with the temperature, and as a rule there is but little difference; two plants of one kind do not always bloom at the same time. There are few, if any, basket plants that bloom at the times you name. Some of the Tropaeolums might. Triumphant de Gand is one.

BIRDS EATING FRUIT TREES (Leontus).—You may to some extent render the buds distasteful to the birds by making the trees or bushes thoroughly wet by watering or syringing, and then scattering fresh-shaken lime and dry soot upon them, which will adhere to the trees or bushes. A better plan is to string the bushes or trees with worsted from branch to branch in all directions, forming a network with large meshes, which, though irregular, will scare the birds.

COMPOST FOR HYACINTHS (Carole).—A good compost for Hyacinths is loam from turves six months old, cut 2 inches thick from a pasture, and torn in pieces by the hand, with the addition of one-fourth part of very rotten old cow dung, and plenty of sharp sand. There is no particular culture required for the production of show Hyacinths, and the subject has been frequently treated of fully in our columns. The bulbs that are very firm and heavy are those most likely to produce the best spikes, and, as a rule, the moderate-sized bulbs are best. Large bulbs that are soft and light, with the scales open, are the least desirable, for they invariably have open spikes of bloom.

HISTORY OF PLANTS (A Subscriber).—Stephanotis floribunda is a native of Madagascar, introduced by Mrs. Lawrence, of Ealing Park, in 1842. Streptocarpus ovatus was introduced in 1777 from the Cape of Good Hope; Pergularia odoratissima from the East Indies in 1784. Of Clorodendron fallax we have no notes.

CUCUMBER-GROWING (Pulborough).—Mr. Hamilton died many years since.

EPACRIS MAGNIFICA (R. M.).—The flowers are pink, tipped with white.

VINES IN POTS (A. Z. Y.).—Your Vines in No. 6-pots we would advise you to top-dress and start as soon as you like. Those in 16-sized pots, if you wish fruit from them, we would plunge, or partly plunge, or place the pots, after making holes in them, in others of larger size. If you wished to bring them in late, you might put into 12 or 8-sized pots, making the soil firmly, and then plunge the pots in a bottom heat of from 75 to 84°, whilst you left the tops exposed to the cold for six weeks before you put them into heat.

FLOWER GARDEN PLAN (Jacobs).—You may sow all the seeds you mention, and have flowers in time. Of course you have the Pelargoniums of which you speak. We would make your three little beds more interesting, say the circle 3 filled with Bijou, with a band of purple Verbena; and 2, 2, scarlet Verbenas, with a string of Cerastium, or Blue Lobelia. No. 1 we would plant with Delphinium formosum and Aceratum mixed, then a band of Calceolarias, then Anemones, followed by Bijou and edged with Calendraria uniflora. No. 1, plant as proposed, and if you use Lobelia for 2, 2, use your Pansies instead for edgings.

HOUSE SEWAGE (Idem).—We would not use chamber slops for a lawn. If diluted with five times their bulk of water they will benefit all growing crops if applied to the roots and kept from the foliage. When used at all strong on lawns, these will become brown and patchy. All the Cabbage tribe will be much benefited by the application.

VINEY BORDER (Lore).—A 12-feet border will do for a 12-feet-wide house. Plant inside if you can manage it, and let the roots go out. Every day we find the inconvenience of outside planting. In making an outside border, raise it as much as possible above the general level. However made, have a drain in front; if there is a cold clay bottom, concrete it, and place from 6 to 9 inches of open rubble over it, and on that turf reversed, if not straw, to keep the soil from the rubble. If the natural soil is good add fresh to it. If all is to be new, choose the top spit from a pasture, or such fine loam as may be obtained from the sides of the highway. To every curbed, or cubic yard of this, add a barrow-load of rotten dung, a bushel of fine rubbish, and a peck of broken bones. If too much at once, you may make the border in three pieces instead of all at once. Many garden soils, with the help of a few broken boiled bones and a mulching of dung every year, the old being taken away before the new is applied, will grow Vines as well as the new soil. For such a late house we would recommend white Grapes—Royal Muscadine, White Frontignan, Buckland Sweetwater, and Trebbiano; and three Black Hamburghs, one Black Champaign, one B-perone, and one Trentham Black.

VINE-PRUNING (A Notice).—In your case we would take up your Vines 6 inches from the front glass, rub off all the buds on the stems, and only leave one or two at the top—i.e., at the bottom of the rafter, cutting back to that length when longer. We advise this on the supposition that you do not mean your Vines to fruit in front, but to have a clear stem as far as the lower end of the roof rafter. This is desirable when the front glass is to be used for other purposes, as plants, Strawberries, &c. If you meant to fruit your Vines from the front border up the front glass, as well as under the roof, then, as the Vines have been planted only six weeks, we would cut to within 6 or 8 inches above the border, and take only one stem from each in summer. By this means you will have bearing wood in front next season. The treatment in either case will be good just in proportion as you wish the Vines to bear in front or not. If to be in front, the stems there should be a foot from the glass.

LENGTH OF HOT-WATER PIPES (Squire Ficker).—We have had little experience with 2-inch pipes; we like 3-inch better, and would say that unless made hot your 2-inch pipes will not be sufficient in severe frosts if you cannot cover up part of the house when such severe frosts occur, say from 20 to 30 below freezing point. Instead of your 12 feet we would prefer 60 feet of 2-inch piping, as then the piping would not require to be so hot. Little piping soon becomes waste, as you need more fuel to make limited piping warm. For having a boiler in the house we do not think you can better Kiddell's. We presume you light it outside. For such a small house, merely to keep out frost, a brick stove would be sufficient; but we have no doubt the pipes and boiler would answer. You can easily add another pipe if necessary.

ICE NOT KEEPING (L. McAl.).—We presume that your house, like No. 2, as shown in the number for July 19th, 1874, is all below ground. If so, and your roof is thick enough, and you have double wall, with a space of 12 inches between them, we cannot tell how it is, the ice does not keep if you put plenty in. At the first raining we thought your house was above ground, and in that case the keeping will entirely depend on the walls being airtight, and the roof double, or thick enough to keep heat out. In one such case the outer wall became open, holes made ingress for air, and then the advantage of the double wall was destroyed. Care should be taken to have such an ice well open as short a time as possible in summer. We do not advise you to fill up the 12-inch space between the walls with charcoal, coconut fibre, &c., or even sawdust, which would do as well, because if the house is of any size it would require a large quantity of material to do so. To keep the ice, to prevent the ice being exposed as now to a temperature in summer of from 50 to 55°, and from being enured in such a steaming vapour as comes out of the door every time you open it, we would advise the following: 1. Make sure that all melted ice in the shape of water shall pass off from the bottom without letting air in, by means of a trap always filled with water. 2. Make sure that the walls are sound, especially the outer one, so that in no point, above or below, shall air enter the hollow space. 3. Pack the ice well, but use no straw at the sides. 4. As soon as the ice subsides a little, say by March, cover the surface of the ice with a foot of clean, dry straw, and change when it becomes damp. 5. Have a pipe of 14-inch bore passing through the roof or over the doorway, with a cowl over it to keep moisture out, and fitted with a cork or plug, which you can open in close, warm, moist weather, so that all vapour shall escape freely. Nothing melts the ice quicker than such vapour.

BURNING CLAY (J. N. S., York).—It is easily practised. Farmers call it “parring and burning.” Gardeners call it “charring,” and under this title, at page 310, of the 5th volume of our First Series, you will find full directions.

VINES FOR ORCHARD HOUSE (Orchard House).—There is no better variety for growing in pots in an orchard house than the Black Hamburgh. White Muscadine or Buckland Sweetwater will succeed planted outside and trained up the rafters inside. Lady Downe's would not ripen Grape in such a house.

PEACH TREES IN POTS (*W. S. Chelton*).—We are not much surprised that your Peach trees in pots did not fruit last summer, after being taken up and potted from the open ground in the previous winter. To succeed, you would have required to have assisted the roots out of doors with a little bottom heat before the tops were excited, as lately detailed by Mr. Fish in "Doings of the Last Week." We like at least to half-plunge such pots in a cool house, as it saves watering. It is never a bad plan to set the bloom; but the best security for that is soil, not wet nor dry, but genially moist, plenty of air, and the absence of frost. If these little matters are attended to we have no doubt the trees will be fruitful this season if the wood is matured. We are not sure of the Black Grapes. For Mrs. Pollock Pelargonium, fibrous sandy loam and a little rotten sweet leaf mould and silver sand bring out the colours well.

MUSHROOM BED IN POTTING SHED (*A Very Old Subscriber*).—If the pottling shed is exposed and has no artificial heat, the bed should be at least from 15 to 18 inches in thickness. For this, horse droppings will be best. If these are scarce, dung such as is used for a Cucumber bed will worked up to admirably, and all the better if 2 or 3 inches of droppings can be placed on the surface. Whether the bed be made at once or in several layers, with an interval of some days between putting them on, it is important that the bed should not heat violently, and one of the best means of preventing that is to make it as firm as possible; and the spawn should not be inserted until the heat has declined to 85°, and is likely to remain at that. Then insert pieces of spawn of the size of a walnut, about 7 inches apart, an inch under the surface, and beat firmly down again. Watch that the heat does not rise; if not in a day or two, cover with 1½ to 2 inches of fresh loamy soil, and beat firm, leaving the surface quite smooth. If the trial-stick shows the heat is gently declining, then cover with a little clean litter, or old useless hay, and before the Mushrooms appear regulate the covering so that the bed in the centre shall be about 70°, the surface of the bed from 60 to 65°, and the air around at from 55 to 60°. Many minute directions, and with different materials, have been given, and if you tell us exactly how you are situated we will advise you.

RIDGE CUCUMBERS (*Idem*).—These will in many seasons grow out of doors in the open ground. The dung from a Rhubarb or Sea-kale bed, thrown into a heap and fermented, and then placed in a trench with the soil over it, will generally give heat enough for out-door Cucumbers. Lately the atmosphere has been more in fault than want of heat. If the locality is cold we would keep hand-lights over the centre of the plants all the summer.

TWELVE SELECT VERBENAS (*W. H. M.*).—Mrs. Deans, Foxhunter, Le Grand Boule de Neige, James Walton, Goliath, Inimitable, Reine des Roses, Champion, Rose Rendatler, Monsieur Gourdault, Mrs. Wood, and De Precy.

TWELVE SELECT DAHLIAS (*Idem*).—Imperial, Fanny Purchase, Beauty of Hilberton, Edward Spary, Bob Ridley, Andrew Dodds, Anna Keynes, Criterion, Paradise Williams, Vice-President, Lotty Atkins, and British Triumph.

MARÉCHAL NIEL ROSE (*R. S. S.*).—You should at once shift your small plants into larger pots, using a compost of rich light turfy loam, enriched with one-fourth part of thoroughly rotten manure or leaf mould. Afford them an airy, light situation. It will not be necessary to prune them, but you may, if you wish for a better, stronger growth, cut the shoots back to within two or three eyes of the old wood.

LILY OF THE VALLEY AND VIOLET PLANTING (*C. L. K.*).—You may procure plants of any nurseryman. You may plant them in good, rich, light soil in an open situation, 6 inches from plant to plant, in rows 1 foot apart. The earlier they are planted the better. The Violets you should also procure at once, and plant in rows 15 inches apart, allowing 1 foot from plant to plant in the row. The situation should be partially shaded, and a liberal addition of leaf mould may be made to the soil.

TRANSPLANTING LAURUSTINUS (*Nemo*).—You may remove the *Laurus* at the end of March or early in April, taking care to lift it with a ball, and to water if the weather prove dry afterwards. It may it may be cut-in if at all irregular in growth, and will grow all the better for it.

PORTUGAL LAUREL NAKED AT THE BASE (*Idem*).—You may cut it in as you propose, but not to the extent you name. In cutting it back leave as many of the small shoots as you can, for they will put out fresh shoots more freely than the stronger branches. Early in April would be a good time to move the Myrtle.

VARIOUS (*C. E. S.*).—Your Pelargoniums that have been kept dry through the winter should not be watered until next month, and then you must not supply moisture in excessive quantities, but by degrees, increasing it as the plants grow. It is too soon to bring *Fuchsias* and Pelargoniums from a cellar. Early next month will be a good time. We would mix the horse droppings with the straw from the stable, throwing them into a heap, and turning over once or twice before forming a hotbed, and at each turning sprinkle with water if the materials appear likely to become dry. In this way the heat will be milder and more lasting, and the rank steam will be dissipated. Separately the horse droppings will not do well, nor the straw, but mixed they would answer well. Fowls' dung is an excellent manure, and you may use it in your garden. You cannot sow *Calceolarias* seed now and have the plants in bloom this year for bedding purposes. Cuttings put in now would do well. (*A Young Gardener*).—"Kitchen Gardening" will suit you, and Keane's "Out-door Gardening." You can have them free by post if you enclose five postage stamps for the first, and twenty postage stamps for the second. There is no better chance for a gardener in the island of Jersey than in England. If you need employment there you must advertise in a Jersey paper. If you write to Mr. Richards, Assistant Secretary, Royal Horticultural Society, South Kensington, asking for information, he will send you particulars. Any gardener can go in for examination.

PRUNING ROSES (*Idem and B. Burlington*).—"Cut the Manetti-stocked Roses to the first plump eye in sound wood at the tops of the shoots; cut in the side wood to a sound eye, and thin-out all useless wood. Do not let the centres of the plants be crowded. A free circulation of air promotes health. Cut back at once the Manetti stocks which are budded. Mr. Gill, at Blandford, cuts back his budded Manetti stocks at the fall. My Manetti Roses were thinned-out and shortened after the blooming season. Very little need be done now. I cut back very short this week what few Briar-stocked Roses I have. The sap is very abundant in both Briar and Manetti Roses here. Roses in England generally are not pruned early enough. Much depends on the character of the year.—*W. F. RADCLIFFE*."

NAMES OF FRUITS (*J. S.*).—*Apples*: 1, Scarlet Nonpareil; 4, Embroidered Pippin; 5, Royal Russet; 6, Hanthouse. *Pears*: 1, Geodebien; 2, Benrie Diep.

NAMES OF PLANTS (*T. Bevan*).—The specimens were not numbered, so we cannot refer to them.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending February 11th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

GAME COCKS' TAILS.

In reply to the remarks of "EXETER," I have to state that I have noticed the "whip," or "switch" tails in three articles at least, and intend to notice them further. I consider, and always shall consider, the hard, stiff, fanned or spread tail, when neat, to be the gamest form of tail, as the very act of carrying the tail up and fanned, or spreading, shows spirit, and contrasts best with the proper, short, close, hard body and hackle feathers; and the drooping or rather drooping-compressed tails approach the Malay type too closely, and show less spirit and pride in my opinion.

As to the drooping tails, I have never seen a good Game cock with a drooping tail. I certainly do condemn black marks in Brown Red cocks' breasts, and hens with black bodies as not pure or as being cross-bred birds, but all Brown Red hens have striped hackles. I condemned only the yellow-hackled Brown Red hens, and advocated the dark copper red hackle in good

Brown Red hens; if pure-bred, both have, of course, striped hackles.

The original colours cannot, in my opinion, be improved by crossing colours, and the proper way to cross is to "breed to match" with different but good blood. Crossing different colours only produces vulgar mixed colours and spangled mongrels, I think; and though I like "crossing to match," I decidedly object to crossing different colours in breeding, and so do most of the best breeders.

I consider that the term "Partridge" is far more correct than "Grouse," for the hens of the Black-breasted Red cocks, and is also far more generally used.

By crossing different colours you will generally obtain far less handsome markings, and less correct markings, than by "crossing and breeding to match." As to which are the true original colours of Game fowls of each variety there are diverse opinions, but all seem to agree that Brown Reds and Black-breasted Reds are original, but differ as to the exact original type of these two old and favourite colours. As to tails there are, of course, various forms, and at exhibitions I believe the whip or switch tails are the better general

favourites at the present time. The close form of tail has nothing to do with hardness or closeness of body and hackle feathers in my opinion. To call the Duckwing hens Partridge-coloured would be, indeed, an absurdity, I think.—NEWMARKET.

P.S.—In my description of the cup and prize Brown Red hen, at page 81, I omitted the colour of tail, which should be of a dark blackish brown colour.

LIGHT AND DARK BRAHMAS.

"THE exception" is said to "prove the rule." The chorus of just dissatisfaction at the treatment of the Light Brahmas is interrupted by a solitary voice, raised by one who has left his old love, the Light variety, for its rival, and who is well contented with the present *régime* under which the cup invariably goes to the Dark Brahmas.

"Y. B. A. Z." is a doughty champion, and one may well admire his pluck as, wearing the honourable scars of so many combats, and dealing, as he has done, with such a variety of subjects, he places lance in rest for a tilt at the Light Brahmas.

Having expressed, through your kindness, my views at some length, and seeing no reason to change them—being, moreover, fully convinced of the justice and ultimate success of the cause of the Light Brahmas, I would not trouble you again were it not that I feel it courteous to "Y. B. A. Z.," as he has appealed to me more than once, to make some reply to his letter, and this I will do as briefly as I can.

I do not take exception to your correspondent speaking of Mr. Worthington and myself as enthusiastic admirers of the Light Brahmas; but I would remind him that Mr. Worthington, as well as Mr. Crook, who wrote so ably in page 83, are breeders of Dark Brahmas as well as of Light, and therefore are not likely to be partial to the one breed over the other, and that both these gentlemen are loud in denouncing the present system as unfair to the Light birds.

"Y. B. A. Z." says, that as shows are sometimes not successful, it is hard upon secretaries to expect them to give cups to both Light and Dark. Mr. Worthington and I both meet this difficulty by suggesting separate prizes, less in amount if need be, for each variety; in other words, the same money given as now, but more fairly divided.

"Y. B. A. Z." asks why, if both varieties of Brahmas have a cup, should not all the breeds of Cochins and Hamburgs have one also? forgetting that these latter have a far more equal chance in competing one variety against another for a cup, than the Light Brahmas have against the Dark.

"Y. B. A. Z." goes on to speak of the improved position of Brahmas in the prize lists, and asks, quaintly enough, whether Dark and Light Brahma exhibitors are to be still dissatisfied? The answer is obvious: the Dark which always take the cup have no cause for dissatisfaction, the Light which never take it have much! He goes on to speak of the "degeneration" of the Light Brahmas. The judges will tell a very different tale. In numbers, in correctness of points, in beauty, they are far ahead of what they once were. I shall not forget Mr. Hewitt's pleased comments on the class (of over twenty pens) at Southampton last autumn, when such was the general excellence that birds which had won many a prize had to be content with commendations!

I am grateful to "Y. B. A. Z." for his allusion to my old cock, which was indeed declared by the judges to be as near perfection as possible, but I am bound to say that the general average of Light Brahmas is much improved; and were he still alive, he would have to compete, though, I doubt not, still successfully, with a larger class of "foemen worthy of his steel."

"Y. B. A. Z." objects in the case of the Brahmas to the judging of two or more classes competing for a cup on the only true and possible principle of equity—namely, the comparison of each specimen with the standard of its own breed. He candidly admits the justice of the principle in the similar case of Geese and Ducks.

Lastly, he imputes inferiority in many respects to the Light Brahmas, and then builds upon this supposed inferiority a theory that the breeding for colour has done all the mischief. He will forgive me, if I say that he does not seem to see that by so doing he puts himself out of court in the question at issue between the two varieties, for how can he be a judge of the comparative merits of Light and Dark Brahmas who substantially denies that there should be any difference of colour between them, or, at all events, makes colour a matter im-

material, and who looks upon them as one and the same breed? Clearly he would not be the best judge of the relative merits of blue and green who deemed blue and green one and the same colour!

Before concluding, let me say how delighted I am to see what sympathy Mr. Worthington's appeal has met with in your columns. From England and Ireland, from London and Southampton, from Alton and Limerick, from breeders, exhibitors, and secretaries of shows alike, comes the same unanimous voice, that Light Brahmas ought to be placed on an equal footing with the Dark.—JOHN PARES, *Postford*.

P.S.—Since writing the above, I have read the letters of "NEMO," and "BENGAL," in the last Journal. The remarks of "BENGAL" are most just and forcible. Secretaries will be wise if they adopt his advice, and that of Mr. Warren, the able Secretary of the Southampton Show, and establish equality between Light and Dark, giving, if possible, cups to both varieties, and, in any case, separate prizes.

"NEMO" is, I think, right in maintaining that the under fluff of Light Brahmas should be, not white, but of a bluish grey. My old cock, Sampson, so often mentioned, and whose merits all your correspondents seem to have recognised, possessed this characteristic. Plenty of good birds at the present time possess it also.

"NEMO" is also right in saying that the theory of the Light Brahma being a "cross" originally, is utterly untenable. The original imported birds depicted in Miss Watts's book, were Light Brahmas, not Dark, and may connect the latter variety with the Coloured Dorking in origin; the similarity has frequently been pointed out to me by careful observers at shows. Be this as it may, I should be very sorry to introduce White Cochins into my yard, with a view of "improving" what "NEMO" most justly calls such "exquisite beauties" as pure Light Brahmas. "NEMO" concludes with a most valuable remark—he most wisely calls the attention of judges to the fact that Light birds look smaller than Dark ones, when they really are not so.

Though a breeder of neither the Dark nor Light birds, and therefore writing without favour or affection, may I be allowed a few words on the question now agitated in your columns? When Mr. Pares speaks of "the best relatively of its own variety," I imagine he means the same things as "Y. B. A. Z." does by the "comparative merits;" for if a cup be given to two varieties, we may fairly assume that there is one ideal standard of excellence for both—that is, if a represents such standard for Dark, it does also for Light; for if we say the standard for Light is A—B, then an inferiority on their part is assumed, and it is a farce to offer a prize to the two varieties when one is assumed to be necessarily superior to the other. It is as though a competitive examination were open to black and white boys, and a certain number of marks allowed to the black; or as if a cup were offered to black and grey horses, with an understanding that the grey must be the worse; in this case the dark horse would be sure to win, and no one would "bet on the grey," no one would even enter a grey. But in point of fact it appears that judges will assume this superiority on the part of the Dark birds. The fairest thing would therefore be, instead of giving a cup, to divide the money between the varieties, or what would, perhaps, be better, to give the cup in alternate years to Dark and Light, and then we may say to the breeders of both—WHY BE AFRAID?

HAMBURGHS *versus* BRAHMAS.

It requires some audacity in the face of the prevailing worship of the feathered Brahma to come forward and proclaim him as great an impostor as his Hindoo namesake, but if you care to have the experience of a convert you may insert this communication.

At the commencement of last year I was red hot for Brahmas. I spent a fair amount of money in purchasing a cock and ten hens and pullets of various strains. Of the hens six were allowed to run with the Brahma cock. The remaining four, with three half-bred Cochin hens, were put in a separate run with a Dorking cock. I also had a third run, in which I had a Golden-pencilled Hamburgh cock, two hens, and a pullet. The runs were side by side, and the fowls all had exactly the same treatment, each lot being let out alternately for a run in a large field, generally for half the day. As I could not always distinguish the eggs of the Brahmas from those of the half-bred

Cochins I must class them together, but as far as I could judge the latter were the better layers. By the end of the year the three Hamburgs had laid 476 eggs, and the thirteen Brahma and half-bred hens 734 eggs—i.e., the Hamburgs averaged 158.66 eggs per hen, and the Brahmas, &c., only 56.46 eggs per hen. Of course, some of the latter were occasionally occupied with sitting and rearing chickens; but allowing for the time it would have required to break them off from sitting if they had been wanted for laying only, this would not have made very much difference in the result.

I may add, that I reared a good many chickens of both breeds, and could not discover the slightest difference in the matter of hardiness. I do not think I lost a chicken of either breed from disease.

As for the superiority of Brahmas for winter laying, the simple fact that for some time the only eggs I have had are from my Hamburgs, while the Brahmas content themselves with consuming vast quantities of barley and afford no return, is the best answer I can give.

Undoubtedly Brahmas are larger fowls for the table than Hamburgs, but as they eat at least in proportion to their greater bulk, there is not much economy in that. They are also decidedly superior in every respect to Cochins, which I have also kept, and where the poultry-keeper is compelled to keep his unhappy fowls in a small back yard, he cannot do better than keep Brahmas, especially as they resemble nothing so closely as a small heap of cinders on two legs, and can, consequently, be warranted not to show dirt.

If, therefore, the amateur who keeps fowls principally for their eggs has sufficient space, I should strongly advise him to keep Hamburgs; if he has room to keep two kinds separate, or prefers pure breeds, then Brahmas also, as they will do the hatching and rearing part of the business as well as any fowls. If he wants a good and handsome table fowl, he will find a cross between a Brahma cock and a Silver-Grey Dorking hen first-class. The hens from this cross are almost exactly like the parent hen, except in the shape of the comb and in having a few feathers on the legs. I have seen an old hand deceived by them, thinking them to be pure Silver-Greys. Of course, they are vastly more hardy than pure Dorkings. The opposite cross of a Dorking cock with Brahma hens is not so good, as the chickens are more leggy.—OORNILUS.

P.S.—Not the least objection to Brahmas is the appalling ugliness of the chickens, contrasting strongly in this respect with Hamburgs.

FOUR-TOED HOUDANS.

MR. SCHRÖDER has suggested what I have no doubt will appear to many, including myself, a step "forward," by breeding out the "backward" toe of the Houdan. Is it not, however, written in chronicles immemorial that the Dorking must have the useless monstrosity too, and how can his Houdan offshoot want the same? Did the supernumerary create speed, like the "seven-leagued boots," or strength as in the six-digitated giant of Gath, or delicacy of taste, or beauty of form, then indeed the excrescence would be tolerable; but failing all these, is this wonderful member to be venerated and conserved as a relic of the primeval and barbaric age of poultry?—JAMES C. COOPER.

MERITS OF BRAHMA POOTRAS.

IN this, my first epistle to the Journal, I will just jot down the doings of a few of my strain of Dark Brahmas; it may, perhaps, interest some of your thousands of readers.

I coincide with your remark, that a fowl cannot lay eggs and make feathers at the same time. I have one that has laid ever since the 30th of October, 1866, only excepting the time she hatched and reared nine chicks, which process occupied just seven weeks and two days. Now, up to to-day she has laid 279 eggs, all good, but she has been in moult for the last five months, and at the present time she is without feathers under the wings and breast; notwithstanding, she looks hearty and well, and to all appearance is likely to go on laying for some time yet. Our clergyman thought, although she was so good a layer, it did not follow that her produce would be as good. Now, to show that she has been beaten in her first fifty, we possess one of her pullets which has laid fifty-five eggs in the same number of days—that was from the 1st day of September up to the 1st of November, just two months. She then took to clucking, and sat for a few days, and stragge, as it seems to me, took to

moulting when only about eight months old. She has had a thorough shift, has recovered from it, and has laid ten eggs since. I also possess a pullet which laid ever since the 10th of November, with the exception of missing four days in the time. One more is worthy of mention—the smallest hen we have laid forty-one eggs in forty-one consecutive days!

Time will not allow me to further transgress, only I would like to remark that we never see an advertisement for the sale of Brahma eggs, except of those of some strain that has taken a prize. Now, if such a thing as a competition were to take place for the best Dark Brahmas for egg-producing, I should, perhaps, stand a chance, although, probably, it might be a small one. However, all who see my fowls declare them very good; whether they are judges or no I will not say.—J. P.

A NATIONAL ORNITHOLOGICAL ASSOCIATION.

I HAVE read with much interest the article emanating from Polefield Hall, which appeared in your issue of January 16th, as well as that by my coadjutor in the south. The idea of forming a—what shall I call it?—perhaps, an All England Ornithological Association—has long forced itself upon my mind as being an object to accomplish which no effort should be spared, and I hail with great satisfaction the munificent offer which accompanied Mr. Bedwell's pithy but most expressive suggestions.

I am not writing officially, but I think I can safely say that the Committee of the Association I have the honour to represent will supplement Mr. Bedwell's offer with another £20, and I am open for any amount of work to assist in giving this project some tangible form. With this view I shall be glad to hear from Mr. Bedwell his idea of the framework of such an Association, with some details of its objects, and the best methods of giving effect to them. Till then I feel as though it were, perhaps, rather premature to offer any suggestions; I will, however, follow up Mr. Warren's remarks if you can spare me a little more space.

I regard the formation of an All England Association as a great means of doing what very few, if any, isolated societies in England can do unassisted—that is, offer year after year to the United Kingdom a complete schedule, and a liberal scale of prizes. I do not think it fair that any one society should be called upon to do so from its own immediate resources, should find the sinews of war, and throw the doors of its exhibition open to all the breeders in the kingdom; but a combination of societies can do this, and do it on a very grand scale too; they would be in a position to issue a schedule embracing all varieties of birds: they would not be hampered by considerations as to whether such and such a class would pay, but rather by supplying such a prize induce exhibitors to compete for it. This would of necessity give an impetus to breeding, and it would soon be patent to those concerned that commercially it would pay as well as "breeding Pelargoniums or bees." I need adduce no plainer proof of this than the fact, that the introduction of certain classes into the schedule of the North of England Ornithological Association at the last Sunderland Show created a position for birds hitherto comparatively worthless, and that many were claimed at prices from 25s. downwards. The idea of being able to do collectively what cannot be done individually is to me the most prominent one. The mode of organisation, method of government, &c., will soon suggest itself if gentlemen who take an interest in our feathered favourites will assist in ventilating the subject in these columns.

A "Standard of Excellence" and a method of judging by it will each be a *sine quâ non*, nor do I see any difficulty in arriving at such. If the most celebrated breeders of any given class of birds had each of them a certain number of points to divide among the different properties of such birds, the mean result of the aggregate would give a standard at once. That there are men fully competent to judge upon sound principles I am confident, and an extension of the basis of operation would as a natural consequence develop their talents. I am not acquainted with many public judges, but those I have come in contact with appear to be men quite up to the day, and thoroughly able to perform their duties—to mention names would be invidious.

I should like to call the attention of all likely to take a part in furthering this most interesting scheme to one very important matter, and that is to the imperative duty of enacting the most stringent laws to insure common honesty in showing birds. Perhaps that is rather too strong, and a libel on the

many sterling exhibitors who would scorn to tamper with a bird. Well, I apologise, as a friend of mine always says after uttering a disagreeable truth. "But until managing committees and hon. secretaries act resolutely," writes a gentleman to me who was victimised at the Crystal Palace last February, "do not look for support from those who would esteem it a privilege to help you."—WILLIAM ANTHONY BLAKSTON, *Secretary, North of England Ornithological Association.*

CLASSES FOR DUCKS—RETURN CHARGES.

Is it right that Mandarins, Carolinas, Shell Ducks, Wild Ducks, &c., should be exhibited at shows which are only for domestic poultry, and are in most schedules so entitled?

We find that the prizes are mostly given to these varieties, and that tame domestic varieties, such as Black East Indians, which breed well, and are such splendid birds not only on the pond but on the table, where it is said nothing can equal them, are now never looked at. I think it is time some attention should be devoted to this matter.

Again, is it right that in the Any other variety class judges should give the prizes all to one variety, ignoring the presence of first-class specimens of another variety? I find much written now in "our Journal" with respect to separate classes for Brahmas, but in my opinion the time has now come when a separate class should be given to the Black East Indian Ducks. At only two of our best Shows is this done—Birmingham and Manchester. At the former I have noticed that the amount of the entry fees exceeds the prizes offered by pounds, thus proving that a separate class would pay committees of shows; and such is, I think, the due of the large numbers who now keep this variety. Much more to the purpose it must be to give more varieties in a schedule than to subdivide the varieties already named in schedules.

I quite agree with the letter signed "PARTRIDGE COCHIN." I sent two pens to Oldham Show; they cost going, 1s. and 1s. 6d.; coming back, 1s. 6d. and 2s. 6d., and in every instance of late have found the same thing. Surely something ought to be done to remedy it.—S. B.

CANKER AND ROUP IN PIGEONS

HAVING read the inquiries made whether the diseases of Pigeons are infectious, I may mention that I have been a Pigeon-fancier for the last thirty years, although I think that this will be the first time my attention has been so attracted as to cause my name to figure in print, and I do so now merely to state my experience.

Some time ago I purchased a lot of twenty birds from a gentleman who advertised in your Journal. I had ten the first time all right. I afterwards sent for five other pairs, which were duly delivered in three days, they having to travel 150 miles. When I received the last lot they were, as you may imagine, more dead than alive. I had them all cleaned, and put them by themselves until they recovered from their late travelling. After they had been some time mixed with my stock, which consists of high-flying Tumblers, several pairs of Carriers, and Antwerps, I found one or two moping about. I immediately examined them, when I found to my sorrow that they had the canker. I took them away from the stock, and endeavoured to cure them, which I did by using the only way that I think they are to be cured. I had a stick furred out at the end, and I removed all the yellow matter which collects where canker is, and which would, if not stopped, spread, and in a very short time suffocate the bird, such being the termination of the disease. I then procured Johnson & Son's improved mounted caustic No. 8, in wood; with plug or screw tops, they are to be obtained at any chemist's, and excellent they are; no fancier should be without one, which he can carry in his waistcoat pocket without annoyance. With the caustic I touched the parts affected, taking care to cleanse the mouth with a soft cloth.

I was very unfortunate, for out of the ten birds I destroyed six, the others I made a cure of; but, worst of all, many others of my stock caught the canker, which I attribute to their drinking out of the same fountain, and they were all very healthy birds and in fine feather, and that denotes a Pigeon's being in good health. I have lost ten or twelve birds since, and I have taken every care of them, but the canker has spread among them; therefore I firmly believe that it is infectious. If time would permit I could relate many such cases.

As regards the cause of the disease, I think the birds being penned up so closely, and being short of food, they naturally eat their own droppings; and probably there may have been food put in the hamper in the first place, which had become mixed with the droppings.

Of roup I have not the same dread as I have of canker, for I believe it is not infectious. I have seen dozens of cases similar to that which Mr. Huie has pointed out, in which one bird has had it, the other not, and all the billing they did, did not affect the healthy bird. I am trying the recipe Mr. Heath recommended for it, hoping it may be the means of curing many of my birds at present suffering from it—a circumstance I attribute to the very damp season and to my Pigeon house having a stone floor, instead of a boarded one, which is very much better.

I think there is another cause of birds having the canker, and that is drinking from out of leaden spouts on the roofs, where the water lodges.

About five years ago I had a stock of 120 birds, consisting of Tumblers, Carriers, and several pairs of first-rate Antwerps, which were imported to me direct from Antwerp. My fountain is a self-feeding one, holding about three gallons of water. I took upon myself to clean it one day. My shot-pouch being at hand, and thinking that would just do, I emptied it into the fountain, and after giving it a good shaking, took out all the shot, as I then imagined. After some time my birds began to show signs of sickness—no apparent disease, but a gradual falling away, and many of them fell dead when in the act of flying. I am sorry to say I lost upwards of thirty birds before I found the secret out, which was I had left some of the shot in the fountain, and if I had not found it out in time I believe that I should not have had one bird left.

I have always through the moulting season, and, in fact, all through the winter, used the herb rue; taking a handful, and letting it remain covered with water in an earthen vessel by the fire, afterwards pouring it into the fountain, and it assists the birds to moult freely, and keeps them warm in winter.

Weak birds when moulting I always assist by pulling feathers from both their wings and tails, and always with success. I feed my birds on broken Indian corn mixed with barley, and I have them always in good feather.—R. PRITCHARD, *Ludlow, Salop.*

AN AMERICAN APIARY.

I HEREBY make a statement of the proceeds of an apiary owned by myself and son. We had at the time the honey harvest began about 115 swarms, very lightly stored with honey; in fact, three-quarters of them had none, for we fed them daily on cheap sugar to keep them from starving through the spring. They began swarming June 14th, and ended August 11th, the Italians taking the lead by at least two weeks, and swarmed later by three weeks: the last one that came out was from a young Italian swarm, and gathered honey enough to winter. We now have 201 swarms, and sold one, making ninety young stocks, worth 10 dols. each, and 7225 lbs. of surplus honey.

The account stands thus:—

Honey sold in glass caps, to date	6155 lbs.
Honey strained and sold, to date	350 "
Honey strained, and on hand, to date	240 "
Honey in boxes and on hand, to date	380 "
Honey used in the family, and given away	100 "

Making in all

I think the above statement is not far from correct, as we kept the account. Our bees are mostly Italian, and I believe are as pure as can be found anywhere, bred by Wm. W. Carey, of Coleraine, Massachusetts who possesses superior advantages for keeping the Italian bees pure, and is a man perfectly trustworthy in all respects.

I think we have greatly increased the value of our bees by the introduction of the Italians; it seems to give new life and energy to all their movements, however slight the mixture. I have given the amount of honey our bees have collected; and now I will give the product of a single swarm of hybrids I have in a large box hive, which cast a swarm June 20th, that I put in a hive in which I use four glass boxes, and from which we took fourteen full boxes, of 7 lbs. each. The mother stock cast a second swarm, from which we took four boxes, making eighteen boxes, or 126 lbs. from the two. I then transferred the old stock, and should think it would weigh 100 lbs., there being no young to hatch. I think the contents separate from

the hive would weigh 75 lbs., which, added to the surplus above, made 201 lbs., and three good swarms for wintering. We had other Italian swarms that did equally well; one cast a swarm and made fourteen boxes, and the new swarm made five boxes, besides some parts of boxes, and cast a swarm; another came off July 2nd, and filled twelve boxes. Our honey was mostly from white clover, and sold for 30 cents a-pound.—DORR BRIMMER, Hoosick, N. Y., December, 13th, 1867 (*Boston Cultivator*).

A BEE FLOWER.

AN excellent bee plant is the *Phacelia tanacetifolia*, or Tansy-leaved *Phacelia*. It is a tolerably hardy annual, some seeds of which were brought into this country from California in the year 1832. Although but little cultivated, it is remarkable for its elegant foliage and fasciated spikes of violet flowers, which continue to blow during the greater part of the summer and autumn months, but chiefly in June, July, and August.

This plant is easily raised from seed, which should be sown in the spring in ordinary garden ground, and it requires no protection after the severe frosts are over. Besides being a great acquisition to apiarians and to amateur bee-keepers on account of the special attraction of its numerous flowers for bees, it is highly ornamental, and deserves to be generally grown in flower gardens, and in the neighbourhood of apiaries.—W. T. C.

ECONOMY IN COAL.

LAST spring (*ride No.* 318, vol. xii.) I brought before the readers of "our Journal," the plan of flooring grates with sheet iron, which I had then, on good authority, recently adopted. My notice was supplemented by a few approving words from the Editors, and some lines which conveyed in rhyme a speech of Serjeant Warren, who was the originator of this plan for economising coal. I am now, having practised the plan one full year, able to speak of results.

In the years 1866 and 1867, I have had the same number in family, and the same fires in the house, and when examining the two coal bills, I find that for 1867 just one-quarter less than that for the former year, and the coals have been the same price per ton each year. Thus a decided advantage is gained, the expense of fuel being reduced one-fourth, consequently a coal bill of £12 would be reduced to £9; one of £8 to £6; one of £4 to £3. I have been particularly careful in my calculation, in order that there should be no possible exaggeration. Newspapers and common report stated that the cost of coal would be reduced one half; but this is not the case, but a reduction of one-fourth is certainly worth obtaining by so small an outlay as 2s. for a piece of iron wherewith to floor each grate. I press this plan, therefore, upon our readers, whether wealthy or poor; the former to adopt it in order to increase their charity purses, the latter for the sake of economy. I have found during the last year that we have had as much or even more warmth, and that the fires do not go out for hours. Even occasionally a fire lighted at noon one day, has without any intention been found still burning the next morning. In this case, most probably, it was packed together, and added to late in the evening.

Now I am speaking of economy, let me add, as an old house-keeper, I have found that the pig tub and the cinder pit are the two receptacles for the extravagances of the cook and the housemaid. If the master is known to have an eye over both these (the pig tub and cinder pit), he will prevent a great many things being made away with, which ought to be eaten or used in the kitchen, which said things too often are put in a pig tub. And, oh! the large cinders that are thrown into the cinder pit. In this new plan of flooring grates with sheet iron, not a single cinder ought to remain, except these taken off before going to bed, and which serve to make a fire with in the morning, and light more readily than coals. Except these lumps there ought to be only ashes.—WILTSHIRE RECTOR.

OUR LETTER BOX.

PREVENTING HAMBURGS FLYING (*T. H. N.*).—It is one of the amusements of Hamburgs to fly over any wall. Anything is preferable to cutting their wings, as that not only disqualifies, but it spoils their appearance. You must either put an upright netting on the top of your 8-feet wall after the manner of a tennis ground, or you may, and we think it a more effectual remedy, put up the netting leaning over towards the inside. We have known birds confined by this that would have flown over any upright fence.

FOWLS DYING OF INFLAMMATION (*Sarbiton*).—We think boiled liver chopped-up with pepper is enough to account for any inflammation. We can give no better advice to any poultry-keeper than to follow nature. Where would a fowl find boiled liver dressed with pepper? and what state of body would require it? All such feeding is bad, and will cause only sickness and disappointment in your yard. Feed on meal, alaked with milk or water; vary it with barley, Indian meal (rarely), kitchen scraps, table sweepings of crumbs. Supply garden refuse, especially lettuces, freely; if the fowls' run does not afford it, let them have some heavy seeds of growing grass, cut with plenty of fresh earth hanging to them. Eschew stimulating and unnatural food.

POINTS OF HONDANS (*Leicester*).—We give you the points of Hondans taken from the best French authorities and endorsed by our best judges. We will answer your questions as they occur. They must have five toes, and beards, and small top-knot or lark crest. Yellow feathers are a disadvantage, but red ones are a disqualification. Amateurs should insist on all these points. To ignore or overlook the lack of them, is to open the door for the introduction of crosses and mouscadescripts, the drafts and refuse of yards, that cause disappointment to amateurs, and bring an otherwise good breed into disrepute.

PRIZE POULTRY (*K. Hall*).—It is quite possible to rear prize-taking Brahmas or Cochins-Chinas in a space 36 feet by 40 feet, with the run of a quarter of an acre for six months annually. The earlier they are hatched the better.

TEMPERATURE OF INCUBATOR (*R. B.*).—The temperature needful for hatching eggs is 105.

POULTRY FARM COMPANY (*J. Wright*).—If such a company exists it is a simple contract debt, and you must sue them in the County Court. If the company does not exist, then goods have been obtained under false pretences, and you ought to employ the police.

SELLING EGGS (*Hemcliffe*).—The price you speak of is a retail famine price. Few can afford 3d. for an egg, and there is only sale for a limited number at such a sum. In addition to this, the scarcest time is past. You could have sold for a fortnight before Christmas, and for a fortnight after, at high prices, but the supply now increases daily. If none of your friends can buy a fresh egg for less than 3d., it will pay for three or four to club together and have them from you. A basket of eggs will come from a long distance for less than a shilling.

SENDING BUTTER AND EGGS BY RAIL (*R. B.*).—Put the butter in an earthenware jar, and the eggs in bran.

FAILEN COMES (*A Northampton Bee keeper*).—Slightly raise one side of the crown board and blow under it a few whiffs of smoke from a cigar-charred fumigating tube, or a smouldering roll of linen rags. Then in about a minute boldly lift off the crown board and take out all but one or two of the frames and detached combs, brushing the bees off them and back into the hive with a stout feather. Having replaced the crown board the abstracted combs should be conveyed in-doors, and there secured in their frames in the manner described in page 84 of the "Gardener's Almanack." When all are fixed they may be replaced in the hive, and the operation repeated on a smaller scale with the one or two remaining combs. Keep a sharp look-out for the queen, and carefully protect her from injury during your manipulations. Select a fine mild day for the operation, and do not on any account resort to fumigation.

SAVING AND UTILISING CONDEMNED BEES (*E. H.*).—No honey runs out of the cells, and, consequently, none is lost by inverting a hive for the purpose of driving.

FEEDING BEES (*Querist*).—There was an error in the reply to "G. J." in our last number. The latter end of this month (February), should have been the time named for the commencement of spring feeding, instead of "next month," as therein stated.

LONG-FARED RABBITTS (*T. W.*).—If you refer to our No. 537, published on the 12th of last September, you will find stated the essentials for breeding them. You know that warmth is essential, yet you "expose them to all kinds of weather!" Their hutchies should be kept in a warm outhouse; and if it be kept artificially warm—about 60°, all the better.

ASTHMATIC AND BALD CANARY (*M. C. Dixon*).—The asthma and baldness from which the Canary is suffering is the cause of cold, or most likely it has been kept in too warm a place, and not had sufficient water. If it has been hanging too near the ceiling, and gas or coke has been burned in the room, the same effect would be produced. Change its situation, and give some egg boiled hard, chopped fine, and mixed with a little mawseed; also give a little green food, such as water cress, and plenty of fresh water, in which put a little saffron, and the feathers will most probably appear when the moulting season comes round. The finest singing birds for the cage are the German, but they generally do not continue in song so long as a good Norwich bird. If you refer to other cage birds it remains entirely a matter of fancy, they are so numerous.

LOVE BIRDS (*A Constant Subscriber*).—Love birds are to be purchased at Mr. Hawkins's, Bear Street, Leicester Square, or of Mr. Judd, Newington Butts, and most of the respectable bird dealers in London. The price is from 25s. to 30s. a-pair.

SQUIRRELS.—"L. R." wishes to know if Squirrels eat the grub contained in the oak-gall. His gardener assures him he often sees them doing so, and the ground under the oak trees is covered with the remains of the oak-galls.

POULTRY MARKET.—FEBRUARY 12.

We have still a very short supply. The conclusion of the Game season and the near approach of the Parliamentary season, make us hopeful that our long period of depression will lighten, if it do not disappear.

From observations taken near London during the last forty-one years, the average day temperature of the week is 46.6; and its night temperature 31.9. The greatest heat was 67°, on the 26th, 1846; and the lowest cold 8°, on the 20th, 1855. The greatest fall of rain was 0.92 inch.

GLADIOLUS CULTURE, AND FOR ROOM DECORATION.

DESERVEDLY the Gladiolus has become a favourite flower, and many of its varieties are so reduced in price that it is now almost within the reach of the cottager.

This flower has many good properties. Perhaps one of its greatest is its suitability for decorative purposes. When cut and intermixed with other flowers for the drawing-room it will not wither in two or three days as an ordinary flower does, but, with care

and attention in taking off a little of the lower part of the stem, supplying fresh water, and removing the decaying blooms, a succession of expanding buds enables it to retain its place for a fortnight at least.

It can be advantageously appropriated to window decoration, interspersed with other plants to form a contrast. Take a bottle, of which the neck must be sufficiently wide to admit the stem of a Gladiolus, and plunge it into soil in a flower pot—a deep, narrow pot is the most suitable for this purpose—fill the bottle nearly full of water, and cut a spike the height that may be required, introducing a few blades of its foliage to give it the appearance of a growing plant. By attention as above, by keeping up a supply of fresh water, and, of course, preventing the rays of the hot sun from falling directly upon the spike, I think that all who try this method will feel themselves compensated for the slight trouble they have taken. Those who grow the bulbs in beds or groups can always take a few spikes for this purpose without materially injuring the appearance of the garden: hence one of the advantages of grouping.

A succession of bloom may be kept up by amateurs or gentlemen's gardeners for from four to five months. There are two ways of accomplishing this:—1st, by planting at different times; 2ndly, by a careful selection of large and small bulbs.

Perhaps I may here be permitted to say that I have been an ardent florist for more than forty years, and have cultivated bulbous-rooted plants to a considerable extent. I commenced the culture of Gladioli as soon as they came into repute, and have paid special attention to them. They are more hardy than the generality of people are disposed to think; however, I paid a penalty in testing their hardness by losing upwards of two hundred bulbs; but, under ordinary circumstances and in a favourable situation, they may with safety be planted, weather permitting, in the latter part of February or the early part of March. When they are about to break through the surface, a little protection is necessary, such as straw, dry litter, or cocoanut fibre; but for those who can afford it, thick Nottingham lace hooped over about a foot high is less unsightly, and can easily be removed every favourable day.

Some persons recommend artificial heat, this I strongly object to for bulbs that are intended for the open ground; but if early blooming is required, I rather prefer to plant in pots, and plunge in a cold frame, choosing my largest bulbs and the early varieties for this purpose; in fact, I

consider it a good plan to plunge in this way, at different periods, to obtain a succession of bloom when there is convenience at hand to do so.

In potting for the cold frame, first insert crocks, then a little sound turf mixed with sand and leaf mould; next put in the bulb, and cover it with sand and crushed charcoal, filling up with the previous compost. Be cautious not to give too much water. When planting out, remove the top soil, or rather turn it back, and add a little more sand and charcoal.

I would impress upon all cultivators of the Gladiolus the absolute necessity of a dry bottom or good drainage. I have been rather amused at the detailed account given by "B., *Darlington*" (see page 4), of his friend's mode of growing. He digs out his bed to a depth of 3 feet. (It being strong soil, I hope there is a drain from the bottom.) The first layer consists of 4 inches of turf; then I calculate that there will be 9 or 10 inches of rotten cow dung (it is a pity to waste such good stuff; it often cannot be obtained), and 18 inches of turf and loam; then come the bulbs in cocoanut fibre, and 4 or 5 inches of turf and loam upon this, making the 36 inches. Had I to make up his bed, and 3 feet deep, my experience would lead me to proceed as follows: 6 inches of brick rubbish, then turn back upon this 8 inches of the top soil taken out, with a little sand added, as it is strong; upon this 5 inches of the rotten cow dung, and 13 inches of the turf and sandy loam; then my bulbs smothered in a little clean river sand, mixed with bruised charcoal, completing with 4 inches more of the turf and sandy loam, of course thoroughly incorporated.

The following, which is my own mode of culture, I have invariably found successful:—Bed 30 inches in depth; bottom dry, of course. Turn back 10 inches of the top soil taken out, put in 4 inches of old cow dung; then well-mixed turf, sand, and loam, with the addition of a little old leaf mould, if certain of its containing neither fungus nor anything to create it, to the depth of 12 inches. I then plant my bulbs smothered in a little clean river sand, or the drifted sand from the coast, which I prefer, mixed with crushed charcoal, and a covering of 4 inches of turf and loam. Protect as above. I do not object to silver sand, but it is in some cases more expensive, and I consider the other quite as advantageous.

I am not an advocate for growing Gladioli in beds unless the blooms are required for exhibition; when this is the case, the bulbs should be planted 8 or 9 inches apart each way, leaving a groove between the rows for the purpose of applying liquid manure, if necessary, as I strongly object to any kind of manure coming in close contact with the bulbs. It is better, as a safeguard, to water the bed slightly before applying the liquid manure, and also again after doing so.

If not wanted for exhibition, I prefer grouping five or six bulbs together, or as number and convenience suggest, the soil being prepared in the same manner. In the autumn, when I take up my bulbs, I treat them in the same way as I have done Tulips—simply dry them, and protect them from frost during their time of rest. I throw out the soil upon a space prepared for it to the depth of the

cow dung. I then have the cow dung forked up with a portion of the soil below it, turning this over frequently to temper it thoroughly, at the same time turning over what had been previously laid out. When planting time draws near I add a little more rotten cow dung, and then fill in the soil that has been thrown out. This I have done for three years in succession, and have never been disappointed with the result.

When leaf mould is introduced, let it be leaf mould, not rotting leaves. Nothing to my mind is more injurious than decaying sticks or timber. Pieces of rotten sticks are invariably mingled with decaying leaves, and as invariably fungus is produced. Of all edgings for beds, avoid wooden ones; the boards and stays employed are almost certain, sooner or later, to produce fungus, a consequence of all others to be feared. I do not know of anything else which has such an injurious effect upon bulbs.

The disease of the *Gladiolus* is a perplexity to all cultivators who have suffered by it. From close observation, however, I attribute it mainly to the following causes:—1st, Too tender nursing; 2nd, Atmospheric influence; 3rd, By manure being brought into close contact with the bulbs; 4th, To a fungus, which may be introduced by manure, rotting leaves, decaying timber, &c. Of these the first two are, in my opinion, the principal. Bulbs started in bottom heat are more subject to become diseased than those planted in the open ground, especially if not properly hardened in a cold frame previous to planting out; when so stimulated, they are incapable of sustaining the severity of the shock to which they are subjected on being planted out. As soon as the growth of a plant is from any cause checked, it at once becomes the prey to atmospheric influences. If your readers will take the trouble, when they observe a plant becoming unhealthy, to examine its foliage with a microscope, they will find it minutely specked or blotched. On continuing their observations daily, they will find this appearance extend gradually, till ultimately the plant sickens, the disease having then penetrated the bulb. I have sometimes tried sulphur dusted through a fine muslin bag, and have thought with success, but have not sufficiently tested this to recommend it as a remedy.

There appears to be some doubt as to how far the roots of the *Gladiolus* penetrate into the earth. I should recommend those who are desirous of proving this to introduce, when planting, a piece of thin, common window glass, about 18 inches long by 10 wide, perpendicularly into the soil, close to a medium-sized bulb, and when the plant is in full bloom, to take away 4 inches of the soil from the centre of the outer side of the glass, taking care not to disturb it; they will then have an opportunity of deciding how deep the roots really penetrate. Any of your readers who think proper to try this experiment will be somewhat surprised at the result. This will also afford proof as to whether the disease commences at the root or above ground. I have been in the habit of employing this interesting method upon various plants for years.

Since writing the above, I have read with much interest the article by Mr. Tillery, for which I beg personally to thank him. I fully coincide in many of his views, but the means at his command are evidently so extensive that few can act upon some of his suggestions. I therefore still offer my more humble experience for the benefit of amateurs and others who, like myself, are in a less favoured position.—*M., Durham.*

THE ROYAL ASCOT GRAPE.

I HAVE had frequent opportunities of seeing the Vines and fruit of this variety at the Royal Nursery, Ascot, from the time the Vines were started in December, 1866, until now, and have been much pleased with it. I am glad it has gained the appreciation of the Editors of *THE JOURNAL OF HORTICULTURE*. I am not quite certain, however, that it ought to be classed amongst our earliest Grapes. It is perfectly true that it colours earlier than any other Black Grape; and being the blackest of all Black Grapes, and having fine large berries, it was acceptable in market before the Black Hamburgh, and brought 2s. per pound more than the latter. I did not, however, think it quite ripe; and it possesses so many extraordinarily good qualities that I should much regret to see it recommended for what I am not certain that it is. Having thus expressed a doubt whether it ought to be classed amongst our earliest Grapes, I must state that the plants of it which Mr. Standish has grafted on the Chasselas Musqué, and which produced the fruit to which you refer at page 94, seem to have done their work in maturing and

ripening the bunches in so short a time that I am quite prepared to believe that, grafted upon the Chasselas Musqué, the Royal Ascot will prove the earliest Black Grape we have seen. I must also state that I have noticed the temperature the fruit was produced in has been low. From what I have seen and the inquiries I have made, I believe the average temperature in which the Grapes shown at the last meeting of the Fruit Committee were grown did not exceed 55°, when the temperature had to be kept up by means of fire heat, and this has of course been the case for months. This is an exceedingly low temperature for a first-class Grape to attain the state of perfection in which the Royal Ascot was when shown before the Fruit Committee. I think I can safely say that the bunches did not make their appearance until towards the middle or end of August.

You say it possesses "a richness of flavour which is not found in any early variety except itself." I would add to this that it is in all respects, when fully ripe, the finest Black Grape I have ever tasted. It possesses the firmness of flesh of the finest ripened Muscat, more briskness and piquancy of flavour, without the luscious richness of properly ripened Muscats. I decidedly prefer this Grape when fairly ripe to the most perfectly ripened Muscat I ever tasted.

To what you say about the prolificacy and pertinacity of this variety in yielding a succession of fruit without going to rest, or showing any disposition to do so, I can honestly add that the Vines seem as if they could be kept growing and showing fruit continually; and I have no doubt that this variety can, with proper management, be easily and cheaply ripened, and had in a fresh state any month in the year. I do not think that the ripe fruit now is quite equal to what this Grape was in June last, but in its present state I do not know where to find its equal at this season. It is fresh, crisp, and perfectly delicious.

I have no right to expose Mr. Standish's treatment of this Vine, but a few words as to how the plants which produced the fruit shown before the Fruit Committee were treated may account for the berries not being of the size they ought to have been. The Vines which produced the fruit shown were planted last May in a border of soil not more than 18 inches wide, and on the surface of this were four 4-inch hot-water pipes in two sets of two. The poor little Vines—for they were very small when planted out—seemed to me in great danger of having the little life they had in them roasted out of them. Then they were smothered up with pine plants; and the house was, for the sake of the Pines, kept much too hot for the Vines to have any chance to make a strong growth. After the fruit shown before the Fruit Committee made its appearance, Mr. Standish determined to give the Vines more soil for their roots to work in; but in doing this he found that the roots of the Vines had made their way amongst the materials in which the Pines were plunged, and to accomplish his object he had to all but transplant the Vines, and this after they had shown their fruit. The Vines flagged, dropped some leaves, and showed clearly that they did not like the treatment; but next time I saw them the fruit had made wonderful progress, and the Vines seemed to have quite recovered from the check they had sustained through the transplanting. If the Vines had been planted in anything like a fair border, and left to help themselves without being transplanted, I have no doubt that the berries would have been much larger than they are. I think they are something wonderful, considering the treatment the Vines have received.

I beg to thank you for the information that there is in Italy a variety of Grape which possesses the perpetual-bearing character which the Royal Ascot has shown. This character was to me so extraordinary that I was inclined to fear it might not be lasting, or rather that it might be less strongly exhibited in the course of a few years; but now I know that there has long been a variety with this perpetual-bearing character in cultivation, there can be no fear that the Royal Ascot will not retain this most valuable characteristic. The Royal Ascot requires no such attention as you say is bestowed upon the *Uva di tri volte*, for it never produces a lateral that does not show one, two, or three bunches according to the strength of the Vine.

The constitution and vigour of the Royal Ascot Vine are very remarkable. Mr. Standish allowed the Vines which were planted in the autumn of 1865, in his house of this variety, to carry a heavy crop, which they perfectly matured in May and June, 1866. Then the perpetual-bearing tendency forced itself into notice, and a goodly number of bunches which showed after the first crop was cut were thinned and left to take their chance, the house being kept open and cool. These coloured

and were exceedingly handsome fruit, but they did not ripen nor nearly attain perfection. Later in the season the Vines pushed a fresh set of laterals, and the show of fruit on these was wonderful—two and three bunches on many of the laterals; and this swarm of bunches, or a great part of them, was left until the Vines were pruned in November, and then these seemed as if they would have ripened a fair third crop if they had been fairly treated for this purpose. If I am not greatly mistaken the Royal Ascut will prove to be the best quality of Black Grape we have seen, and its perpetual-bearing character will render it the most accommodating and valuable of all Grapes.—WILLIAM OGSTON, *Gardener to Lord Anwyde, Titnes Park.*

MILKY WHITE AND PATERSON'S VICTORIA POTATOES—THE DISEASE.

I SEE you recommend (see page 63), four kinds of Potatoes. I have grown all the same varieties, also about twenty kinds in all, but I find none so good for general use as the Milky White for early and Paterson's Victoria for late use. I can highly recommend these two kinds as the very best for good croppers, and not so liable to the disease as most other sorts. Last season almost all my Potatoes were diseased, but Milky White and Paterson's Victoria were very little diseased.

One fact is worthy of note—namely, that on a plot of ground near where these kinds were grown was a crop of Onions. These Onions were sown on ground that Potatoes occupied in the previous season, and many of the tubers were left in the ground; consequently they became troublesome, and the tops were kept constantly cut off until about the middle of June, and after this date they were allowed to grow. In the autumn, during digging the ground, we found very good sound Potatoes, although the same varieties that we planted were almost rotten. This seems to indicate that the disease will not attack Potatoes after the middle of June.

I remember some years ago planting Potatoes in July, and had a fair crop, and no disease, but those planted early were much affected. Has any correspondent found late planting good? or do you suppose that the Onions would have any effect in preventing the disease?—HAWKINS.

FRUIT-GROWING IN THE NORTH.

ALLOW me to correct a small mistake in my letter published in your number of January 16th.

After enumerating the first-rate standard Pears the following sentence occurs, "These have not yet borne abundantly." It ought to have been, "The last two have not yet borne abundantly"—namely, *Beurré de Rance* and *Knight's Monarch*. The others bear freely. *Althorp Grasse*, a Pear commended in one of your late numbers, although ripening freely on the wall, is quite second-rate here.—JOHN McCulloch, *Duffus.*

CATERPILLARS ON PELARGONIUMS.

THE large green caterpillar which your correspondent "R. E." finds so destructive to his young stock of Pelargoniums, *Verbenas*, and *Calecolarias* is the larva of the Angle Shades Moth, *Phlogophora meticalosa*.

The moth appears in September and October, and lays a vast number of eggs on almost any garden flower that comes to hand. It is very fond of finding its way into the greenhouse, where, in the warm atmosphere, the eggs soon hatch, and the young larvae keep feeding on the florists' treasures all the winter.

The best plan to destroy the larvae is to go round the house with a lantern at night, when they will be found feeding on the topmost shoots. They generally conceal themselves during the day.

The Brimstone Butterfly (*Gonepteryx Rhamni*), always deposits its eggs in the spring, and upon the buds of the Buckthorn, *Rhamnus catharticus*.—H. HARPER CREWE, *The Rectory, Drayton-Beachamp.*

CUPRESSUS MACROCARPA.—Mr. Robson may be glad to hear that trees of *Cupressus macrocarpa*, both large and small (one 24 feet high), do remarkably well in this situation, which is 800 feet above the level of the sea, much exposed to wind. The soil

is light, consisting of decomposed granite. It succeeds far better than the *Wellingtonia*, which, unless well sheltered, does not thrive here. This is the experience of—AN IRISH GARDENER, *County Wicklow.*

RAMBLINGS—GESNERA CINNABARINA.

OF the innumerable subjects which owe allegiance to Flora, which are ever laying their beauties at her feet, and seeking for the occupation of a niche of honour in her temple, some base their claims on the brilliancy of their flowers, others on the beauty of their foliage, and a third group on symmetrical form and proportions. Some of these subjects, though heralded by a flourish of trumpets, stand but for a moment before the practical gaze of the world, and in obedience to the fiat of public opinion fall into the rear and there remain. On the other hand a few, by a combination of good qualities, hold their own in the front ranks, seeming proof against the ordeal of criticism, and only step back as if in courtesy to their younger followers, being confident that their intrinsic merits will not suffer them to remain in obscurity.

But few subjects possess in combination these elements—viz., brilliancy of colour, beauty of foliage, and symmetry, and still fewer which unfold them in the floral night of winter. There are, however, some. I take for the moment the *Gesnera cinnabarina* as a representative, and will pay a passing tribute of admiration to its qualities in the columns of the Journal, where neither old nor new are refused admittance so long as their merits entitle them to rank as subjects of general usefulness. It is not that I have selected this especial branch of the extensive family of Gesnerads that I wish it to be held in higher estimation than others of its fraternity, there are many kinds which I have never seen, and which, for aught I know to the contrary, may possess equal or greater distinctive features of merit. I am not instituting comparisons, but simply testify to that which I see, and from which I derive pleasure—a pleasure which I am desirous should be participated by all who have it within their reach.

Gesnera cinnabarina is not only a plant of great beauty, but of easy culture and great tractability. It may be had in succession for many months of the year if required; but it is in the dull months of winter when it seems to shine the brightest and last the longest. It is here regarded as a staple plant for stove decoration at this season of the year, and is grown in quantity proportionate to the size of the house. In order that my small resources may contribute to a lengthened display of brilliant colour, I make it a point to have the Gesneras coming in when the Poinsettias are going out. Being more dependant on the weather than those who are provided with properly constructed houses for preparing this and kindred subjects, I cannot always hit a given time with exactness; but I am happy in having an employer whose practical mind can comprehend the entire routine of supply, and who exercises a just discrimination in these circumstances. I am led into this ramble from the fact that other employers more inexperienced may be at times a trifle too exacting, drawing comparisons and arriving at conclusions without giving full regard to conveniences or altered circumstances.

To resume. In the culture of the *Gesnera*, as in the case of other subjects, I have recourse to improved expedients determined by requirements. The tubers of the plants now in bloom were potted in July, a little bottom heat being provided for them by digging the soil out of a frame, which had been put up for seeds and cuttings, and in which had subsequently been grown a crop of early Cucumbers, putting in place of the soil mowings from the lawn mixed with a few leaves, the whole being covered by 2 or 3 inches of sawdust to absorb the gases evolved by the decomposition of the grass and leaves, and to plunge the pots in. The pots used are the same as those in which the plants are now blooming; one tuber being placed in the centre of a 5 or 6 inch pot, three or more tubers being put in pots proportionally larger. The pots were about two thirds filled with soil, and top-dressing added as the plants progressed. A few tubers were put in small pots for shifting on, but these have not done so well as those which have not had their roots disturbed by repotting. The soil used is one-half good turfy loam, the remaining half peat, leaf mould, and thoroughly decayed cow dung, in equal proportions, liberally mixed with sand, plenty of broken charcoal being added to keep the mass open.

The plants remained in the frame until September, the sun supplying the sole atmospheric heat, which was economised by

carefully giving air and early closing, and in nights when the sky was clear, and radiation consequently rapid, a mat was thrown over the glass. At this time, the bottom heat being all gone, and the plants starting, evidently requiring warmer quarters, they were transferred to a shelf near the glass in the plant stove. But why not have brought them in here sooner? Simply because the shelf was occupied by a few late Gloxinias and other plants of a like nature, which I could not dispense with; and herein is the necessity that gardeners should and must at all times exercise their mental faculties in looking ahead—it may be for months, in providing for, to the casual observer, unseen wants, and in avoiding contingencies unknown except to the initiated.

But I am rambling again, and hasten back to say that with the treatment here described the plants flourished, and are now in fine bloom, conspicuous in their scarlet costume amongst their more sober friends the Ferns, and giving an ample return for the trouble bestowed on them in their somewhat chequered career. I doubt not there are hundreds of people throughout the country who have the beauties of this fine old plant brought before them; on the other hand there are many plant stoves into which it does not enter. To the owners of these I say, Get it, and grow it by the dozen, or hundred if you like; grow it well, and then if you are not satisfied with it blame—J. W.

EFFECTS OF LAYERING A VINE.

SOME time back I observed a remark in the Journal by a writer, to the effect that he would never allow a branch of a Vine to be bent down so as to root itself into the border at a distance from the main root. What harm can this do? I should have supposed that so long as the branch was not severed from the parent, it could not be injured by the additional new roots, and that the parent could be as little injured by the extra roots to feed the branch.—F.

[This is a disputed point. We have seen Vines layered in all directions, until it was impossible to know which was the original root or stem; but as a general rule, the result of experience and observation, we have found that Vines do best when all the roots proceed from one part. It is easy to obtain roots from any part of a Vine stem, but in general they are long, and not well furnished with fibres. Even Vines raised from layers on this account are not so much liked as those raised from a single bud, where stem and roots proceed from the same small space. In particular cases the plan you allude to may be adopted, when it is desired to keep on old Vines a little longer without a fresh border and fresh planting.]

THE ROYAL HORTICULTURAL SOCIETY AND ITS GARDENS.

I AM a horticulturist in the sense of being always pleased with pretty flowers. I watch with interest the little groups brought up week after week from Chiswick to Kensington for the decoration of the conservatory or by way of a show. I appreciate the good work which is done at Chiswick in the elimination of many supposed varieties of Peas and Beans with high-sounding names; I even read with interest striking phenomena of vegetable physiology; and yet I am heretic enough to protest against Chiswick being kept up as a neat and trim show garden, and to this end, as it appears to me, your remarks of Thursday last on the Society's operations are directed.

I think it would be a great mistake to "keep up" Chiswick in any other sense than as an experimental garden, and as a nursery for the decoration of Kensington, her "aristocratic sister," as you are pleased to call it. South Kensington and not Chiswick, as you state, is in fact the place where, as far as possible, the results of the Society's agency are to be chiefly exhibited; and unless what you term the Society's "legitimate work" is made to conduce to the amusement of the "miscellaneous multitude" you hold so lightly, the diminished amount which will be forthcoming for horticultural pursuits will soon make itself felt.

People of Kensington and its neighbourhood find a large proportion of the funds of the Society; but whilst they praise and neglect the scientific meetings, as we complacently term our horticultural *réunions*, and talk of, but never visit, our horticultural treasures at Chiswick, they think with me, that all the jewels which will bear the translation should be brought

up for the decoration of the aristocratic sister, especially when she holds her Saturday "at home."

Might it not serve the purpose of some mere of our flower-growers to show us their specialities occasionally, as Mr. W. Paul does? Could not the Council make it worth their while to do so in some way? I see that one of your contemporaries thinks that the band is a sufficient attraction to bring visitors; but this is a mistake. People get tired of a band, and want the eye gratified as well as the ear.—H.

[Our correspondent has mistaken the object of our remarks, which were intended to show that through the present excellent management of the Society, horticulture, and especially the horticultural garden at Chiswick, has received much more aid and attention than formerly, and yet the garden at Kensington looks none the worse, and the finances are very much the better. We are far from depreciating the importance of the garden at Kensington, which, doubtless, now forms an important part of the constitution of the Society; and while we rejoice to see Chiswick maintained as the experimental garden, we would deprecate the neglect of Kensington, which must always be regarded as the show or promenade garden, and which contributes so many enjoyments to a large body of the Fellows.]

EMIGRATION OF GARDENERS TO AMERICA.

I HAVE been a subscriber to your Journal for some time past, and hope to be so for a long time to come. It would be strange indeed, if, in your many pages, I did not now and then find something quite at variance with my ideas regarding various matters, and about which I should like to say a word or two. This desire is especially strong with me just now, since reading "A Few Words Suitable for this Christmas," by "WILTSHIRE RECTOR," in which, after speaking of the manifold struggles of some "gardeners by profession," to make both ends meet, he says, "Ner is it a time for encouraging emigration. . . . Many have recently gone abroad with a little capital, and that being soon spent, have become labourers in a land where a labourer has fewer comforts and more hardships than he has in England."

I have lived where I now am for eleven years, and having had during that time never less than twenty, and often more than forty labouring men in my employ, I am competent to speak of what comforts and what hardships a labouring man usually finds in this country.

This winter the times are especially hard, and so an account of the workman's present condition cannot certainly be considered as putting it in a too favourable light. I have now twenty-nine men employed, each of whom receives for his day's work 1 dol. 60c. in our currency, or about 5s. sterling. This makes the week's wages 30s. If a man has a family he takes this money home and uses it as he may think best; but if he is a single man, he obtains good board and lodging for 5 dols. a-week, or a trifle more than 15s. sterling, thus having half his wages left as clear profit, except such part as he may need for clothing.

Some people are in the habit of saying, that although the wages are so much more in the United States than in Great Britain, still the difference in the price of provisions more than makes amends; but this is entirely untrue. The chief articles of food, although dear, are cheaper here at this very time than they are in England. American flour, and American Wheat, and Indian Corn, are being continually shipped to England, and so are American butter and cheese, and hogs of other American provisions. If, after paying freight and all other expenses, these shipments did not generally prove profitable, this exporting would soon come to an end. In addition to these articles of food that are among our exports, beef, mutton, and most other meats, are cheaper here; indeed, so is almost everything else that we use to maintain life.

The enclosed slip of paper is cut from the New York *Daily Times* of yesterday (January 27th). The freight engagements to Liverpool for the previous day were, as this will shew, 7,500 bushels of Wheat and Indian Corn, 22,500 bushels of corn, 50 tons of provisions, 300 boxes of bacon, 2,500 boxes of cheese, &c.

"FREIGHTS.—For Liverpool there were taken 2,150 bales of cotton at 7-16d. to 3d. by sail, and 3d. to 3d. by steamer, per lb.; 7,500 bushels grain, by sail, at 9d. for corn, or 9d. for wheat; 22,500 bushels corn, by steamer, at 12d. per bushel; 50 tons provisions, by sail, at 30s. to 35s.; 300 boxes bacon,

by steamer, at 50s.; 2,500 boxes cheese, by steamer, at 60s. per ton. Per Glasgow, 100 tes. lard, by steamer. For a port in the United Kingdom, a brig, with 21,000 bushels corn, at 7s. per quarter. For Havre, 65 hhds. tallow, at 1½d. per lb."

Doubtless, those whom the "WILTSHIRE RECTOR" mentions as having gone abroad with a little capital, and having spent it, were prodigal sons, who wasted their money in riotous living, and were ashamed to confess it, turning their faces homeward without ever looking for a day's work. Or else, perhaps, some of them were "gardeners by profession," who without any experience whatever as to difference of climate, put all their small capital into a piece of land bought at a dear rate, and went to work to make a living out of it, but before the experience was gained, the money was all gone. I must confess, though, that generally they manage to make somebody else pay for their experience. For instance, I myself helped to pay for one fellow's instruction last summer. He came early in the spring, and wanted me to give him a job. He said he had worked fourteen years for a Mr. Edmonds, near London, and told me he understood all about the business; that he had been here some time, and knew all about the climate. He talked so well about what he could do, and was so desirous of a trial, that I agreed to give him wages amounting to 6s. 6d. a-day in English money, a man to help him, and the control of the chief part of the garden. He procured what seeds he wanted, and was all ready to begin operations, but he did not quite like the shape of the spade, and some of the other tools. I got other spades and tools until he was pretty well satisfied. "Now, John," said I, "have you all you need?" Only one thing more was wanted, he was to have all his own way, as the splendid results he promised could only be obtained by his being perfectly at liberty to do what he chose. This privilege I conceded, not with great readiness, however, but still willing to make the necessary sacrifice in view of the benefits to be obtained. Once or twice only I was about to make a suggestion or two, but recollecting the promise of non-intervention, I kept silence, and allowed the "fair trial" to go on.

A pretty business John made of it. The mind of man can hardly imagine a more dismal failure. With the exception of the Radishes and the Peas, none of the vegetables we had proved worth the price of the seed that was sown, and the time required to sow it. The early Cabbages have not headed yet, and as this was expected to happen last June, and it is now midwinter, it may be fairly said that they never will.

One day John came to me and said he thought he ought to have some "flowers."

"Why!" said I, "John, I never knew you cared anything for flowers. I never see you looking about the greenhouses."

"Oh, not those flowers," replied John, laughingly, "Cauli-flowers I mean. We gardeners call 'em flowers in the old country for short."

So he set out several hundred plants, "to be sure of having enough." "Well," thought I, "what in the world shall I do with such a lot, unless I sell them? At any rate I'll send some regularly, as long as they last, to the rector of the parish, to Captain Jim, and all my other friends." To my sorrow I record that all this forethought was wasted, for not a single Cauli-flower came to anything but leaves.

At last, one fine afternoon, John came to me and wanted to know if I would pay him what he had coming to him, as he wanted to go to New York, about thirty miles distant, and put his money into the savings bank. He would be back on the following day, he thought.

"John," said I, as I handed him his money, "it is lucky for you that you are not obliged to take your pay in vegetables. Is it not?"

John gave a feeble smile, but made no reply. He never came back. About a week after he left, I said to one of our men that I thought it rather strange John had not returned yet. The man laughed and told me he "guessed" John was "kind o' discouraged, and not coming back no more." It was even so. Several months have gone by; but I still think of him at times, and mentally give a quiet blessing, remembering that we are told to bless and curse not.

So this is the way of it. If John had come from England with some money to spare, he would, no doubt, have gone to work on a piece of ground of his own, and have wasted his money for himself, just as he wasted mine for me.

In this country any industrious labouring man is sure not only of a good living, but of something more; and, with us, the

idea of a man studying economy to the extent of depriving himself of the comfort of a pipe of tobacco, is simply ridiculous. If any man can do more than an ordinary labourer, he can also obtain additional payment for this knowledge. Many a young fellow who has in England only swept out the greenhouses, and carried soil and pots, comes here as a "professed gardener," undertaking the care of Orchids, stove plants, or anything else that may come in his way. How many notable examples of this could I give, were not my letter already too long. But let any gardener who really understands the care of a good collection of plants come to the United States, and he may be sure of a good place and rapid advancement. Very many, if not most of the best florists in this country, men who are living not only in plenty, but in affluence now, are English, Scotch, or Irish, and little capital did many of them bring to these shores, except shrewd heads and willing hands.

As some may think that I over-estimate the advantages of living in this country, I make this offer. I will give a house rent free, and two guineas a-week to any sober, industrious, first-class gardener who desires to try his fortune in our far-off land. He must thoroughly understand the care of Orchids, stove, and greenhouse plants, and must bring a recommendation for capacity from Messrs James Veitch & Sons, or some other parties equally reliable. The above wages I do not consider high, but I am not really in want of any more help, and make the offer merely in proof of good faith. I will make this arrangement for one year at least, and as a further proof of sincerity will deposit ten guineas in the hands of Messrs. Veitch & Sons, to be held by them until the year expires.—GEORGE SUCH, *South Amboy, New Jersey, U.S.A.*

MUSHROOM CULTURE.

I SEND a few Mushrooms merely as a sample of the produce obtained by a mode of culture somewhat different from the general practice.

I make the beds 1 foot deep in front, with a slight rise at the back, and in three layers, the middle one of fresh droppings from the stable, the bottom and top of droppings prepared in the usual way. The top layer is rather drier than otherwise. As soon as the bed is made and well firmed, the pieces of spawn are inserted 1 foot apart, level with the surface, with a slight sprinkling of loam. The bed is then earthed, watered with sufficient warm water to wet the soil through, and sprinkled two or three times a-week to keep it from becoming dry.

Till the beds come into bearing, and even while in bearing, I give a gentle dewing if the surface shows signs of becoming dry. With a temperature of from 50° to 55°, the beds generally come into bearing in five or six weeks.

I have used short litter and droppings shaken from the dung heap after six months for the bottom and top layers with equal success.—G. EDGERTON, *Strawberry Hill.*

[The Mushrooms were an example of very successful cultivation. They were very crowded, and being of various sizes insured a succession.—EDS.]

GALVANISED WIRE TRELLISES.

I CAN confirm Mr. J. Douglas's opinion as to galvanised wire injuring fruit trees, having had some Peach trees tied to galvanised wire, and they cankered at every place where they touched the wire. The same result occurred to some young Vines tied to galvanised wire. They were similarly cankered at every place that touched the wire.

I have never tried galvanised wire out of doors; having experienced such bad results, I should never think of trying it again in any way.—W. SUTTON, *Scrivelsby Court Gardens, Horncastle.*

In the gardens at this place there are upwards of 150 yards of wall furnished with galvanised wire, to which Peach, Nectarine, Apricot, Pear, and Plum trees are trained. I have never observed any injurious effect caused to the trees by it, and it has now been in use upwards of thirteen years. I have heard it stated that it will injure trees if used in-doors, but of that I have had no experience.—H. PERRIE, *Elsham Hall.*

ALLOW me to add my experience of the efficacy of galvanised iron wire strained to walls for the purpose of training trees.

In 1816 and succeeding years I was engaged in superintend-

ing the making of a new kitchen garden, pleasure grounds, and terraces, with walls for the purpose of growing different kinds of climbers, and we used galvanised iron wire strained about half an inch from the wall, in some cases perpendicularly, and in others horizontally. As regards fruit trees of every description, I never found any injurious effect produced by it; in fact, I am so thoroughly satisfied with it, that in my present situation, where we have been carrying out similar work, we have used it to all the walls both inside the houses and in the garden.—GEORGE LAMB, *Colston Bassett, Bingham, Notts.*

ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 18th.

FRUIT COMMITTEE.—G. F. Wilson, Esq., F.R.S., in the chair. Messrs. Stuart and Mein, of Kelso, sent a tall Sprouting Cabbage, which the Committee considered was not of sufficient merit to be retained in cultivation. Mr. R. Tanton, nurseryman, Epsom, exhibited a seedling Potato, called *Red Surrey Kidney*, being a cross-bred between *Bratten's Kidney* and *Napoleon III.* When cooked, the tubers were of a deep yellow flesh, close texture, and indifferent flavour, and altogether were considered very inferior.

Mr. Earley, of Digswell, sent a dish of *Scorzonera*, and one of *Salsify*, both of which were unusually fine. The mode in which Mr. Earley produced them was by putting a good dressing of manure, about 3 or 4 inches thick, at a depth of 10 or 14 inches. Mr. Earley also exhibited fine specimens of *White Spanish Onion*, and a dish of *Mushrooms* containing the white and brown varieties. Messrs. Wood and Son, of Maresfield, sent what was supposed to be a seedling Apple, but which proved to be the *Winter Pearmain*, or *Duckbill*, an Apple extensively grown in Sussex. Mr. Alfred J. Clarke, of Longwood House, St. Ebbe's, Oxford, also sent a seedling Apple, which proved to be *Franklin's Golden Pippin*. Messrs. J. C. Wheeler and Sons, of Gloucester, sent a dish of fine specimens of *Asbmead's Kernel*, which were most delicious in flavour, and in fine condition. Messrs. J. & C. Lee, of Hammersmith, exhibited a fine large Apple, similar in appearance to the *White Calville*, and with the same delicacy of flesh, but without the flavour. There was some doubt as to its being the *White Calville*, and the determination of the name was reserved. Mr. John Cox, of Redleaf, exhibited dishes of *Joséphine de Malines*, *Knight's Monarch*, *Passe Colmar*, and *Old Colmar Pears*.

Mr. Tillery, of Welbeck, sent magnificent bunches of *Gros Guillaume* and *Trebbiano* Grapes, each weighing about 4 lbs. They were sent to prove that the Vine, grown on the restrictive system, was not deteriorated after nineteen years' growth, which was the age of the Vines producing these bunches. When twelve years old, the Vines were lifted from the borders and transplanted into the new gardens seven years ago; they have grown full crops for the last five years, and have continued to produce large bunches similar to those exhibited. Mr. Miles, gardener to Lord Carrington, Wycombe Abbey, sent specimens of old *Lady Downe's* and new *Black Hamburgh* Grapes, but the former were much superior to the latter in flavour. Mr. Myatt, of Deptford, exhibited three pots of preserved *Plums*, *Strawberries*, and *Cherries*, to show how well jams of these fruits keep by covering the pots with paper dipped in a solution of isinglass.

FLORAL COMMITTEE.—This meeting was one of the most interesting that has taken place. Bearing in mind the early season, and its being the first Tuesday meeting of the Society's session for the present year, it must be considered a great success. The Orchids exhibited so numerous were of the highest order: there were specimens of unusual splendour and rarity. Messrs. Backhouse, York, sent *Oncidium canthium* (?), said to be excavatum; and W. Brackston, Esq., a large specimen of *Gardneria radicans variegata*. Mr. Sherratt, gardener to James Bateman, Esq., exhibited three spikes of Orchids, among them *Odontoglossum cordatum*; and Mr. J. Hodges, gardener to E. Wright, Esq., Gravelly Hill, Birmingham, four cut spikes of Orchids, *Cattleya Walkeriana bulbosa* was very fine. A special certificate was awarded them.

Mr. C. Allen, gardener to Capt. B. Glegg, exhibited a box of fine cut flowers of *Camellias*, among them a seedling named *Miss B. Glegg*, a pretty white flower with broad carmine stripes, but deficient in outline and form. A special certificate was given to the collection. Mr. Forsyth, gardener to Baron De Rothschild, Gunnersbury, sent three fine specimens of *Dendrobium* in full flower, for which he was awarded a special certificate. Mr. Graham, Cranford sent a specimen of a *Violet* called *Victory*, a seedling from *The Czar*; it had been trained as a tree *Violet*, and bore large, purple, extremely high-scented flowers of good substance, with broader petals than any yet raised. The Committee much wished a specimen of *The Czar* had been sent with it to have compared their merits. How very interesting it would be if, at the next meeting, any person whose speciality is the *Violet* would bring a named collection of these sweet flowers. We see many new names of *Violets* advertised, but they never appear at any of these meetings. Messrs. E. G. Henderson sent a very pretty group of plants, containing a specimen of a variety of *Odontoglossum Alexandriae*. The flower of this with a rosy shade is not equal in form to many varieties that have been seen. In this collection were a variety of *Hippeastrum pardinum* with confused spots; *Camellia Florentine*, with

a soft rosy tint, something like *Valtevaredo*; and *Cypripedium Lowii*. A special certificate was given for the group.

Messrs. Veitch sent a large collection of plants, perhaps the most beautiful group we have yet seen. It contained many specimens of Orchids. The following were selected as very fine specimens, and were awarded special certificates:—*Lycaste Skinneri*, with thirty-four flowers; *Angraecum eburneum*; there was also a *Cypripedium*, probably *venustum*, with twelve beautiful flowers; *Laelia Puleheri*, one of Mr. Donny's hybrids; *Cypripedium villosum*, which also received a special certificate; *Dendrobium Hillii*; and *Hippeastrum pardinum*. The whole collection was so good, and the plants so well grown, that after the complimentary award of a special certificate had been given, the Committee recommended that a medal should be awarded to this very superb group of plants.

Mr. Weatherill, nurseryman, Finchley, exhibited a collection of *Cinerarias* of all shades of colour, some of them of great beauty; also some fine *Primulas*, and a fine lot of seedling *Cyclamens* covered with flowers, most admirably grown. A special certificate was awarded to each of these collections.

Mr. B. S. Williams sent an excellent group of plants; among them were *Gongora* species, which was much admired, *Saccolabium Huttoni*, *Cypripedium villosum*, *Hippeastrum pardinum*, and *Calanthe vestita unguis*, which received a first-class certificate. A special certificate was awarded for the collection. Mr. Stevens, Ealing, sent a small group of *Variegated Zonal Pelargoniums*, some of them of great promise, but at this season no one could presume to decide upon their merits; also some *Primulas* and *Cyclamens*. A special certificate was awarded for the three collections. Mr. Woodward, gardener to Mrs. Torr, Ewell, Surrey, sent a small group of plants of great merit, containing *Lycaste Skinneri*, *Gleichenia spelunca*, *Lomaria gibba*, and *Odontoglossum pulchellum*. A special certificate was awarded for these plants.

Messrs. Lee, Hammersmith, brought specimens of *Thujas* for comparison. They came under the different names of *Thuja Zuccarriana*, *T. laevis*, *T. virginica*, and *T. pyramidalis*. Mr. Kinghorn also brought specimens of the same. The Committee was of opinion that these apparent varieties were all forms of *Thuja Zuccarriana*, to which was awarded a first-class certificate, as a handsome and hardy evergreen. Mr. Wm. Paul exhibited *Juniperus japonica nana*, which received a first-class certificate. Inquiry was requested to be made as to its history. Messrs. Lee also sent *Eonymus japonicus elegantissimus argenteus*, which received a first-class certificate, being a very ornamental and hardy plant. Messrs. Smith, Dulwich, sent a specimen of a double red *Azalea*, *François Deslois*, the colour rather dingy; also, some curious seedling *Primulas*, which it was requested should be sent again, and a dwarf double reddish variety. Mr. Wilson, gardener to W. Marshall, Esq., sent a very nice, though small, collection of Orchids. Among them was a fine specimen of *Odontoglossum Alexandriae*, the spike of which, by Mr. Marshall's kind permission, was cut after the meeting, and sent to Her Royal Highness the Princess of Wales. An unusually fine spike of *Vanda gigantea* was sent with these Orchids. *Oncidium leopardinum* received a second-class certificate; others being *Odontoglossum Marshallianum*, nearly resembling *Odontoglossum radiatum*, and a most beautiful Orchid, and *Cattleya amethystoglossa*. A special certificate was awarded them. Mr. Taplin, gardener to the Duke of Devonshire, exhibited the finest specimen *Cologyne cristata* ever seen. This most superb specimen was recommended for the Lindley medal. Mr. Taplin also brought a small raceme of *Amherstia nobilis*, a splendid flower. Mr. Standish, Ascot, exhibited a very handsome seedling *Rhododendron*, from *Boottan*. Some doubt existed about its origin and name. It appeared to be much like *argenteum*, or very nearly allied to it. A special certificate was awarded. Mr. Mills, gardener to Dr. Pattison, sent a specimen of *Odontoglossum Bluntii roseum*, a very pretty variety; and Mr. Earley, gardener to F. Pryor, Esq., of Digswell, a cut specimen of an old plant, *Tenorium frutescens*.

GENERAL MEETING.—W. Wilson Saunders, Esq., F.R.S., in the chair. After the election of twenty-seven new Fellows, the Chairman remarked that the Society had on that day commenced a new session, and under circumstances more favourable than in previous years. If in these greater advances had not been made, it was no fault of the Council, for they had not the necessary funds, but this year it would be found that there was every disposition on the part of the Council to spend as much as they could in the encouragement of good cultivation and new plants. Much of the scientific part of the work of the Society was brought out at the Tuesday meetings, and at these the Fruit Committee and the Floral Committee did their work well, and these meetings were also the means of drawing from the Society's botanical adviser, the Rev. Mr. Berkeley, much useful information in connection with the subjects exhibited. He (Mr. Saunders), on the part of the Council, would urge the Fellows to bring to the meetings all that might be interesting in their gardens, and especially out-door plants, to which of late years it had not been the fashion to pay the same amount of attention as to the inmates of the stove and greenhouse. Many heraceous plants, for instance, are of exquisite beauty, and, requiring very little care in their cultivation, are suitable for the gardens of the multitude, and he was very anxious that they should be more generally grown. Numbers of beautiful out-door plants formerly in gardens, had been allowed to go out of cultivation, and were now only to be found in books, but he would be glad to see them back

again. Among hardy plants not met with at exhibitions were climbers, of which many are very beautiful. He admitted there was great difficulty in bringing them to shows; still, he believed that might be overcome. There were no plants, however, which he wished more to see brought to the meetings than those stove plants which might be used for bedding-out in the summer months, as at Battersea Park. Already a large number of stove plants were so employed, but many more might be added, that required little more trouble in their cultivation than a Scarlet Pelargonium. They would not stand the winter, but why might we not enjoy them in summer? They would be a good addition to our coloured plants—a direction in which we had gone a little too far in flower gardens. He did not want to run down the beautiful bedding plants now employed, but the eye becomes satiated with colour; and what we want is variation, and that we might obtain by elegance of form. The number of plants capable of being brought to bear on this object was wonderful.

There was one other subject to which he would allude—namely, the better education of young gardeners—a subject of great importance at a time when so many new plants are being introduced every year. The higher branches of horticultural knowledge were particularly necessary for those who had to grow them. Without a knowledge of plants, without a knowledge of temperature and the hygrometrical state of the atmosphere, it was impossible to cultivate these plants properly, and many of them were consequently lost. The Council would do all in their power to promote the better education of young gardeners, but he would urge masters to allow young men time, and especially those of them who exhibited a taste for high-class horticulture, to gain a knowledge of the important subjects connected with it as far as practicable.

The Rev. M. J. Berkeley congratulated the members present and the Society at large on the exhibition of that day. He was present at the meeting of the 19th of last February, but the present display far excelled it in point of variety, beauty, and interest. Among the plants at the present meeting Orchids took the lead, and foremost among them was the noble specimen of *Cyclopis cristata* from Chatsworth, which for size and beauty was the finest ever exhibited before the Society. As compared with another specimen of the same species in the room it was in a high state of vegetation, the pseudo-bulbs showing great luxuriance of growth, while in the other plant they were dwindled and angular. Next came the collection of Messrs. Veitch, in which it would be difficult to point out one plant better grown than another. He would, however, especially notice the magnificent specimens of *Augreum eburneum* and *Lycaste Skinneri*, the latter with thirty or more flowers. Of *Oncidium abortivum* a fine specimen was shown at the other end of the room. There had been on several occasions small specimens of this sent, and they attracted very little attention; but any one seeing the plant as shown that day would agree that it is most elegant. The peculiarity of this *Oncidium* was that a few of the flowers were normal, but the rest were without a trace of the column or parts of fructification. The beautiful *Dendrobium* from Baron Rothschild, at Gunnersbury, were then spoken of in high terms, after which Mr. Berkeley referred to a specimen of *Cypripedium villosum* almost entirely destitute of lip, and said that he had met with several instances in which this species had produced flowers exhibiting this peculiarity—that of the lip being reduced to a little curl beneath the column. From Mr. Williams came another plant of extreme interest, and to him (Mr. Berkeley), of extreme beauty, a species of *Gongora* in which the flowers were like carved ivory. There was also from the same exhibitor a little plant of *Saccolabium Huttoi*, which is the same as *Aerides Huttoi*, figured in the "Botanical Magazine." Attention was then directed to the Violet, called *Victory*, from Mr. F. J. Graham, and Mr. Berkeley remarked that though the *Czar*, which has coarse foliage, long stalks, and large flowers, was extremely sweet, *Victory* was even sweeter, and most persons who were conversant with Violets considered it an improvement on the *Czar*. *Leucocarpus alatus*, a plant with white berries, shown by Mr. Wilson Saunders's gardener, was next noticed, and it was stated to be a native of Vera Cruz and the West Indies. It was not a new plant, having been figured many years ago in Sweet's "Flower Garden." If one of the berries were cut across it would be found to be similar in structure to those of *Digitalis*. The plant, from the long time it continues covered with its berries, would be valuable for spring decoration. Two other valuable plants for the same purpose were *Lopezia racemosa* and *coronata*, which had been introduced more than forty-five or fifty years ago, and of one of which he held up a plant to show how ornamental it is when covered with its numerous red flowers. The plant did not flower in the open air, but cuttings taken of it in autumn and struck, made extremely pretty plants for spring decoration. The splendid collections of *Primulas* and *Cinerarias* from Mr. Weatherill were then adverted to, as well as the *Thuja* referred to in the Floral Committee report, and which proved to be *Thuja Zuccariniana*, an extremely hardy and very beautiful species.

Mr. Berkeley then read an extract from a letter from Lord Dunraven, stating that he was in great trouble, owing to a grey lichen which overran the Oaks in his woods to such an extent as to do them great injury, and not only Oaks, but Elms and Thorns as well, in every part of his domains. The lichen, Mr. Berkeley said, was probably *Evernia prunastri*, and in all probability if the ground were well drained it would disappear. Another matter to which he wished to refer was of interest to those who are fond of *Anaxetels*, and who

know how difficult it is to grow them, except under shaded bell-glasses or glass cases. When at Kew lately he found there practised a mode of cultivating these beautiful plants which is different from the common one. They were grown under bell-glasses, one half of which was green, the other half white; the green-coloured portion of the glass affording the necessary shade, while through the transparent portion of the bell-glass the beauties of the plants could be seen. This mode of treatment, he added, had proved extremely satisfactory.

The Chairmen of the Floral and Fruit Committees having reported the awards,

Mr. Wilson Saunders said that in connection with lichen covering trees, he would mention that ten years ago he took an orchard in clayey ground, and finding the trees covered with lichen like the wool on a sheep's back, he saw there were but two courses open to him—cutting down the trees or experimenting. He employed some ordinary labourers to take all the moss and lichen off the stems and branches, and had the whole of the trees painted with a mixture of lime and soot; he had the sod taken off round the trees, and the soil manured well; he then drained the orchard, and last year and the year before it had produced excellent crops.

Mr. Berkeley said that a short time ago he had received from Italy a specimen of a lichen which was destroying the Pines there, and which proved to be *Usnea barbata articulata*. It hung down from the trees in pieces 1½ foot long. Referring then to the mode of destroying the lichen adopted by Mr. Wilson Saunders, he said that though applicable to an orchard it was not so to a large forest like Lord Dunraven's. He recollected the case of an orchard in which were some scarce sorts which it was desirable to save, and the lichens being scraped off the trees, even from every little twig, the result was the entire rejuvenation of the trees.

Even although the afternoon was anything but favourable, there was a better attendance at the Meeting than usual at this early season, and the only regret expressed by those present was that so many of the Fellows had missed so excellent and instructive a display.

IS A DRY OR MOIST ATMOSPHERE THE MORE CONGENIAL FOR SETTING MUSCAT GRAPES?

ONE of your correspondents advocates the keeping of a Muscat house very moist—in fact, to withhold no more moisture at the blooming period of the Vines than at the growing season. I think that is different from the usual practice of our great Grape-growers; I know it is contrary to my practice and experience. Another will guarantee a well-formed bunch, and of course finely set with berries, with a house kept dry, except in respect to a slight sprinkling morning and evening. Which is the road to success, a dry temperature or a humid one? At what time does the adherent to the steaming process have his Grapes ripe? Perhaps he will give some further light on his system of Muscat-growing.—Nemo.

CORDONS.

THE introduction of this word into our fruit-tree vocabulary will puzzle many gardeners who are unable to see any difference between it and our old espalier system of training. No amount of quotations from Du Breuil, or any other French horticultural writer, will make them believe that a branch of a spurred-in fruit tree, whether trained horizontally or vertically on walls or espaliers, is anything else but a cordon. I have no wish to disparage our ingenious neighbours across the Channel for the many fanciful modes of training fruit trees which they indulge in, but some twenty-five years ago there was a great *furor* about a new system of fruit-tree training, introduced from them, and called "*en quenouille*." Fruit trees trained on this system looked very graceful, and bore good crops in favourable years; but young trees are seldom now trained so, either in nurseries or gardens. Whether the name was too difficult of pronunciation, or the training took up too much time, matters not; the fact is as I have stated it. The only use of the so-called small cordons, whether single or double, would be to plant at the bottom of our fruit-tree walls, and I have no doubt that the very best of Pears and Apples could be grown on them. These small trees could be planted between the existing wall trees, and would not interfere with them when trained so low down. I had specimens of *Beurré Clairgeau* 1 lb. in weight each, grown last autumn on a small double cordon, and from being so near the ground they were beautifully coloured. As to growing cordons as edgings to fruit borders, as they do in France, I am afraid our climate is not suitable, from our late spring frosts.

A mode of training Pear and Apple trees was practised by the late Mr. Mearns when gardener at Welbeck, which I believe

would be found preferable to the small cordons for the sides of borders in the kitchen garden. Three larch poles were driven into the ground, and at about 4 feet high the tops were

Fig. 1.

Fig. 2.

Pear trees to plant on the square pillars in the new kitchen garden, where they are trained as in *fig. 2*.

There is no finer sight in a kitchen garden than a long range of walls well covered with fan-trained trees of Pears, Cherries, Plums, and Apricots. Perhaps for low walls, trees trained horizontally are the best adapted, and on dwarf-growing stocks. As there is such a rage at the present time about training fruit trees, allow me to conclude with the following triplet in rhyme, which I think is particularly adapted for the subject:—

"How strange that such a difference should be
'Tween tweedle dum and tweedle dee,
In nanning, pruning, and training a tree."

—W. T.

STRAINING WIRES FOR DIAGONAL CORDONS.

For a length of 100 feet of diagonal cordon wires, the two end posts should be of stout oak about 4 feet out of the ground, and sunk to a depth of 2 feet, strongly supported by an auxiliary stud as in the accompanying representation. Midway between these two straining posts another stout oak post should be put in, to give strength and solidity, and at intervals of 7 or 8 feet light iron supports are necessary to keep the wires in position.

For posts 4 feet high three rows of wires only are really necessary, and these should be placed 1 foot from each other, the lowest being 2 feet from the ground line; but a fourth wire 18 inches from the surface of the soil may be added

with considerable advantage to the planter. This supplementary wire will sustain bilateral or double cordons without any prejudice to the diagonal cordons. They should not, however, be planted in the same row, but inserted at intervals on the opposite side.

A space of ground 100 feet by 6 feet will hold three rows of straining wires for diagonal cordons; and the distance between each being 3 feet, a sufficient space is afforded for the passage of an ordinary-sized wheelbarrow, which is required for the purpose of surface-dressing the trees in spring and autumn. The number of trees which can be successfully planted as diagonal cordons would appear to an old-fashioned planter incredible and absurd; 300 feet of wire will hold 150, and a supplementary row of bilateral cordons. Supposing that dwarf Pear trees on the Quince stock one year old are planted, the produce will be gathered the second year after planting; and if the season is favourable each tree will at this early period average one dozen fruit each of very fine quality—not a bad return for good cultivation.

I ventured during the summer of last year to write a short letter to the *Times*, which the Editor did me the honour to publish, pointing out that fruit trees might be planted by the thousand in spaces of ground now given up to hundreds; but in this letter I suggested the planting of pyramidal trees on a large scale, and I did not allude to cordon trees for gardens.

Your readers can calculate the number of diagonal cordons which may be planted per acre in rows 3 feet apart, and 2 feet tree from tree in a row. I do not, of course, suggest the advisability of covering acres of ground with training wires; but I think the system may be adopted by, and will prove very profitable to, many a small market gardener in the neighbourhood of large towns who cannot afford the ground requisite for planting pyramids, and who will find that by exercise of judgment in selecting the positions, and care in cultivation, unproductive borders may be made to contribute their share to the returns of the year.—T. FRANCIS RIVERS.

WALL COPING

As you say that you wish correspondents to give their experience of wall copings, I beg to send you a slight sketch (*fig. 1*),

Fig. 1.

and section (*fig. 2*), of a wall coping that my father put on his wall some years since. As he could never depend on having any Peaches before it was done (the wall being raised at the same time), and now with the aid of a wash painted on the trees in March, he never fails in having a plentiful crop, it is, I think, worth while to draw your attention to it.

The wall is 12 feet high, and is roofed with Bridge-water tiles resting on a rafter running parallel with the wall, and supported on brackets built into the wall as shown in the section. The projection of the roof is 10 inches. The wall is wired, and the shoots are always tied with the Golden Willow. This plan certainly has the advantage of keeping the wall very sound and affording no harbour for insects, as is the case in the old nail holes, where nails are used. The crop of Peaches last year, when in this neighbourhood there were a good many failures, was a perfect sight.

I may also add in reference to the subject brought forward by your correspondent "H. B.," in page 411 of the last volume, that we fence round young trees in the plantations with short pieces of Elder stuck into the ground to prevent them being injured by rabbits, and the plan has been found very successful.—A SOMERSETSHIRE PARSON.

Fig. 2.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Broad Beans, as soon as the plants of the early crop appear above ground the soil should be carefully ridged up round them, and branches of evergreens stuck in rather thickly on

each side of the rows to afford protection from frosty winds. *Carrots*, sow some approved early sort now, if the ground is in fair working condition, on a warm, sheltered border. *Leeks*, to grow them to perfection, a deep and rather strong loamy soil, highly enriched with manure, is essential. Heavily dress the ground, therefore, with rich, well-rotted manure, and trench to at least a depth of 2 feet. Some growers dig out narrow trenches and fill-in with manure, as is done for Celery; but except with very light, poor soil this is unnecessary. Sow now, if the ground is in good working order, on a bed of rich, well-pulverised soil, scattering the seeds very thinly, and covering them lightly. Choose a well-sheltered sunny situation, and in cold localities it would be advisable to raise the plants in a cold frame, and transplant them in April. *Onions*, the main crop should be sown now that the ground is in good working condition. A rather deep and rich loamy soil is most suitable for this crop; where very large bulbs are desired, soil of this character is necessary. Onions grown in a strong soil are much less liable to be attacked by the maggot than in light, dry, sandy soils. *Parsnips*, sow now in lines from 18 to 20 inches apart, scattering the seeds thinly, and covering them from half an inch to an inch deep with the finest of the soil. Parsnips succeed best in a deep rich soil; and as the application of manure tends to produce forked and badly-formed roots, ground in good condition which has been manured for the previous crop should be selected. The ground should be trenched 2 or 2½ feet deep before sowing.

FRUIT GARDEN.

Take every favourable opportunity to finish pruning, nailing, and washing or painting all sorts of fruit trees, with the exception of Peaches and Apricots. In the case of the Vine, if not cut in autumn, pruning must not be delayed.

FLOWER GARDEN.

Auriculas may be kept moderately moist; if top-dressing has not been done as before directed, let it be done immediately. Look well to *Polyanthuses*. As spring advances the snails become proportionably troublesome; diligently trap them. Plant *Ranunculuses* without delay. The compost necessary is equal parts of leaf mould and loam which has been previously exposed to the action of heat to destroy the eggs of insects, &c., contained therein. Should any soil have lodged in the axils of the leaves of *Carnations*, it is necessary that it should be removed. A quill, with the feather stripped off on one side and cut half off on the other, makes a simple but effectual brush with which to perform this operation, and by timely looking through the stock disease may be prevented. Edgings of various kinds may now be planted, such as Box, Thrift, Daisies, London Pride, or *Gentianellas*. If a few forward patches of *Crocuses*, *Van Thol Tulips*, or *Anemones* in the borders are taken up about this time and carefully potted without much disturbing the roots they will flower beautifully. *Hyaacinths* in glasses will now be showing bloom, and must be carefully attended to. Instead of growing these in glasses I would prefer raising them in pots in the usual way until the flowers begin to show colour, when the bulbs may be gently shaken from the soil, and the roots having been washed in lukewarm water, placed in glasses filled with water of the same temperature. The bulbs will flower as strongly and well as if they had never been moved, and this practice prevents the flower from being drawn, the bulbs from rotting, and the roots from decaying, as often happens when they are grown in water from the commencement.

GREENHOUSE AND CONSERVATORY.

Where large collections of house plants are cultivated, repotting takes place every month in the year, but from this time till August is, in general, the principal period for this work. Many plants may now be safely repotted; early in spring the rule of seeing the roots growing freely is the best guide for beginners. Many plants will begin to grow at the top before their roots are in action, yet they do not require to be repotted; they are either too much confined, or under a higher temperature than they require at this time. *Orchids* from the more temperate regions are often much injured by a high temperature when they begin to grow. *Euphrasies*, *Heaths*, and others of the more hardy plants, in or coming into flower, should be kept near the source of ventilation; while *Roses* and other forced flowers fresh from the forcing pit require the warmest part of the house, and ought to be kept free from currents of air at first. This is a good time to make memoranda of the best varieties of forced bulbs, especially *Hyaacinths* and *Tulips*. The nights are still too long to allow any syring-

ing in the conservatory in the afternoon, but such plants as are not in flower, and all vacant spaces in the house, should be sprinkled two or three times a-week, and this should be performed early in the day. The plants in the greenhouse may now have a slight syringing in the afternoon, and air may be freely admitted in all fine nights. Some young plants may want repotting. If some are growing freely at the top, and the roots are not in action, the house is too hot for them and you must remove such plants to a cooler place. Attend to neatness in all the houses, and make it a rule never to pass a pot-plant through your hands without removing all yellow or injured leaves if there are any, also all insects that may exist on it, as well as weeds growing in the pot. *Pelargoniums* that are growing rapidly may now be repotted; the tops of the young shoots should be pinched off so as induce them to throw out laterals that they may be rendered dwarf and bushy. Old plants of *Musk* may now be turned out and repotted in fresh soil, using rich, rather stiff loam for the purpose. A few of the old roots that will be found on the outside of the ball should be placed regularly over the surface of the pot and covered about half an inch deep, leaving room for water, which must be given freely when the plants begin to grow.

STOVE.

Another crop of dry bulbs and roots might now be started into growth for a successional bloom. It is too soon yet for potting to any extent if the *Orchids* are finished. A few plants here and there may, indeed, be so forward in their growth as to require fresh pots.

FORCING PIT.

This is a good time for propagating many plants by cuttings, by grafting, and by seeds, and the forcing pits are the best places for this work. Seedlings already up ought to be potted-off as soon as they can be safely handled. Foreign seeds had better be sown in 32-sized pots, putting four or more kinds into one pot, and placing labels in the middle facing the different seeds. Less water will then be needed than if each kind were sown in a small pot, and the less water given to doubtful seeds the better chance they will have to germinate. Let every shelf and corner of these useful pits be filled with plants as others in flower are removed from them.

PITS AND FRAMES.

Gardenias, *Roses*, and other plants for forcing will be removed from these to the forcing pit as they are wanted for succession, and their places may be filled-up with return plants from the conservatory which have done flowering. The rest of the permanent occupants require only to be protected from frost, cutting winds, and heavy rains.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

The work has been much the same as in previous weeks with one exception, that of potting a lot of *Dwarf Kidney Beans*, and placing them on shelves in a pit, so as to be equally distant from the glass. For early forcing we prefer pots, as they can be moved as may be necessary, and we prefer planting to sowing at once, as room is saved in the first instance: otherwise time is saved by sowing or planting five or six seeds in a 10-inch pot, three parts filled with fresh light rich soil, and earthing-up afterwards. In growing *Kidney Beans* in a pit we frequently plant first in rows 2 feet apart, when the plants are strong earth-up a little, when they are producing sow again in the furrows, and by the time the latter plants are up and becoming strong, we pull out the first crop and give the second the room, and so sow for four or more crops, giving some rotten dung after the first two crops.

The advantage of growing *Kidney Beans* in a heated pit is, that there is no chance of introducing thrips with them into such structures as vineries and Peach houses. We find in pits that soot water, clear, and at times weak clear sulphur water, used as syringings, will generally keep them free of this their great enemy when fire heat is used, and the syringing cannot be so well done in houses where the Beans are merely a very secondary crop.

It is difficult to decide at times where the thrips come from that will attack the foliage of a *Kidney Bean* plant. In a pit thoroughly cleaned previously as far as we know how, with smoking, washing, lime-washing, and all heated alike, we have put temporary divisions of thin wood, or even of calico, or a mat, and given a different temperature to each division by merely a different regulation of air-giving, and in these diffe-

rent divisions we have had Pelargoniums, Strawberries, Potatoes, and other crops, and all perfectly healthy and clean; still the thrips would begin to show on the Beans by the time they began to produce. We have known instances of gardeners placing a few pots of Kidney Beans in a house as a sort of test or trap for thrips, and whenever any showed themselves, moving the pots out with extraordinary care. When the insects are young this may be safely done; but when full grown it is difficult to get rid of them, they jump so when approached or disturbed. Tobacco smoke in repeated doses will kill them; but it is better in every way to keep them away, than to destroy them after they appear.

Forced vegetables and out-door work much the same as last week, only we have learned that it is desirable to have frequent successions of Sea-kale and to grow it rapidly, as we hear that when it is a long time growing it requires much more boiling because it is much harder. This is a matter that was rather new to us, as Sea-kale in winter was more found fault with on account of being soft and watery, than for its hardness or compactness.

FRUIT DEPARTMENT.

In addition to the matters alluded to last week, we may mention that from frames and orchard houses we introduced a good many *Strawberries* into the houses and a brick pit, placing the pots on a shelf, where drip would be unsuitable in small saucers, and the others on reversed turf on shelves, or on a little leaf mould, with moss below it. From frequent experience, and, perhaps, more especially from that of last year, we would advise that all Strawberry pots for the best part of a month to come, be placed on shelves with merely a thin turf, or a little moss below them, instead of in a raised bed, with a good thickness of mild fermenting material beneath them. From the force of circumstances, we were obliged to use a bed, with a good thickness of decayed leaves on the surface last season, and no plants could have looked better, but the fruiting did not meet our expectations. To keep such plants right they would require to be lifted every day. They very soon root through the pots, and if in bloom, and not lifted for weeks, they would be checked if lifted, and after that the rooting in such material is apt to encourage fine foliage instead of large, well-swelled fruit. Such a bed does admirably if the plants are set on boards, slates, or tiles, with a sprinkling of leaf mould on these to hold a little moisture about the bottom of the pot; but we have often proved that the free going out of the roots into a bed of leaves or leaf mould in January and February, does more to encourage foliage than fruit. When the days grow longer, the sun more powerful, and the plants are not too close together, the plan answers very well after the middle of March. We have found it answer especially well when the fruit was set, or setting, before the plants were thus placed in a material in which they were tempted to root freely. In such a case the fruit had the benefit of the increased vigour, at least a fair share of it.

Air-giving.—We allude to this, because in the last line of the second column, page 139, we meant to say, "When we first managed houses on our own account, we went regularly out to attend *divine service* every Sunday forenoon, and we never had a single mischance from overheating, or too little or too much air, on these occasions." There could be nothing particular in this result, if we attended the houses regularly in the forenoon. We wanted to show to amateurs, that by proportioning heat to light, preventing strong fire heat and powerful sun heat acting on a forcing house at the same time, and giving air early in small quantity, rather than a larger quantity later, the heat of the house would rise and fall gradually within the points of perfect safety, and no casualty would occur, though left to itself for hours. Vineries were often thus left, though forced early, from 9.30 to 1 p.m., and often no change was made until the houses were shut for the night. Of course, they were looked to, and the heavens scanned just before leaving, and immediately on returning; but although like others we could see our failures, we never had one then from that cause. So long as the expense of fuel prevents many of us from keeping on a little air at night even, we would say that air-giving early in the morning is more important than the quantity during the day.

ORNAMENTAL DEPARTMENT.

Will turn over the flower beds already ridged, and dig over larger beds and borders on the first opportunity, and will take the chance to divide stools of herbaceous plants.

Planted Pinks and Carnations well established in a border in the kitchen garden, being afraid to trust them beyond the

walls, as hundreds or thousands of Wallflowers in the pleasure grounds show nothing but a stump of their stems. Dahlias we shall place on the floor of a vinery to come on gently, as we cannot spare a bed for them, though a slight hotbed is the place when much increase is desirable, so as to have fine shoots quickly. Tulips appearing should be protected with little mounds of sand or burnt earth. Crocuses are not beyond the nibblings of the mice; when more grown they seldom touch them. Mice are more easily poisoned than rats. We destroyed a good number of the latter lately by placing poisoned mashed potatoes and oatmeal in holes, and under litter and branches, where no fowls or pheasants were likely to go.—R. F.

COVENT GARDEN MARKET.—FEBRUARY 19.

WE have no alterations to report. Supplies continue good, and the demand is fair.

TO CORRESPONDENTS.

*. We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

BOOKS (*R. M. H. P.*)—The volume on laying out gardens will be published this coming spring. We cannot tell where the *Phacelia* is to be obtained. Apply to the leading seedsmen.

GALVANISED WIRE (*H. H.*)—Any one of those who advertise it in this Journal can supply you.

ROCKWORK (*Idem*)—In Nos. 214 and 216 are directions for making rockwork. In 321 is a list of rock plants. If you enclose twelve postage stamps, ordering them, and stating your direction, you can have them free by post.

TULIP-WOOD (*L. H.*)—We believe that the wood so called and employed by cabinet-makers for veneering, is the wood of the *Liriodendron tulipifera*, or Tulip Tree. At all events the wood of this tree is used for carving and other ornamental work, and for house furniture.

VINES FOR EARLY FORCING (*Tork*)—Have two Vines of each of the following:—Black Muscat of Alexandria, White Frontignan, Black Hamburgh, and Buckland Sweetwater.

ARAUCARIA CUNNINGHAMII SINENSIS.—"In answer to your correspondent 'L. X.,' (see page 119), I am informed by Mr. Smythe that during the first five years the tree in question received no protection whatever, but the severe winter of 1869 killed to the ground large plants of *Araucaria imbricata*, together with Portugal Laurels, the latter supposed to have stood for at least one hundred years. It was then the wish of the proprietor (Lord Soudes), that they, with other small plants of *Araucaria imbricata*, should have the protection of a few sparse boughs which they have since annually received, not that their hardiness is in question, but as a precaution and to make assurance doubly sure.—THOMAS WISEWORTH, Elmham Gardens."

GARDEN PLAN (*A Constant Subscriber*)—Write to Mr. Chapman, Landscape-gardener, Hermitage Road, Richmond, S.W.

PHALANOPSIS SCHILLERIANA (*H. M. G.*)—By putting a little damp moss to the excrecence at the joint on the stem, your hope of a young plant would amount to a certainty. The spike is a very fine one. You can have covers for the last four volumes of the Journal, which will be sent on receipt of 4s. 10d. in postage stamps, along with your address.

VINE EYES FAILING (An Anxious Inquirer).—To root successfully they must be put in before the time you name, and have bottom heat. We should attribute the failure to their being put in late, and to a deficiency of heat. We would advise you to try cuttings without loss of time. If you can have a hotbed put in eyes now, and plunge the pots in it, and then we think you will be successful.

APPLE TREE TRAINING (Idem).—To form pyramids, you should in autumn head down the tree grafted in spring to within 12 inches of the place where it is grafted. From the shoot thus cut back several shoots will proceed; train the uppermost erect, and allow the others to grow; but if disposed to grow erect they should be tied down, and so as not to have all the shoots on one side of the tree, but equally disposed all round. In tying be careful not to break the young shoots. When the leader has grown 12 inches you may take out its point at that height, and it will push again. In September the side shoots, if they are more than 1 foot in length, may be shortened to that; but shoots of less length than 12 inches should not in any way be interfered with beyond tying them down so that they will appear to proceed from the stem nearly horizontally, but with their ends inclining upwards at an angle of about 45°. In autumn, after the leaves have fallen, cut back the leader to 12 inches if it has made more than that length of fresh growth since it was stopped in summer, otherwise it must not be cut back, but in the summer following the leader must be stopped when it has grown 12 inches above the last side shoot. By the above process you will obtain ample side shoots for a well-shaped tree, care being taken to train them judiciously with an eye to the producing of a tree well balanced as regards its shape from whatever point it is viewed. You must not rub off the blossom buds on the central shoot or leader, but leave them, and let them fruit, taking care not to allow too many fruit to remain upon a tree. Half a dozen will be ample, but not too many. If your trees have no side shoots beyond one here and there, your best plan will be to head the central shoot back to a wood bud 12 inches above the place where there is a sufficiency of side shoots, and proceed as stated above.

MUSA SUCKER (Musa).—You may with safety to the parent plant remove the sucker 3 feet high, and instead of its injuring the old plant it will contribute to its vigour. In taking off the sucker be careful not to injure the roots of the old plant, but take away as much soil as you can, so as to remove the sucker with some roots, and without breaking it; forcibly and sharply pulled, it will snap off at the surface like a carrot. The sucker should be potted, and if possible give it the benefit of a mild hotbed, otherwise it will succeed in a house with a brisk heat and a moist atmosphere. The sucker may fruit in two years, more or less according to treatment; the old plant should fruit within twelve months.

ASPARAGUS CULTURE (C. H. S.).—The culture of blanched Asparagus, such as the French send to market, is treated of in page 45, and instructions are given for preparing and planting the beds in page 22 of our present volume, and pages 449 and 441, No. 353, of our last volume.

FRAME LINING (Idem).—Instead of an outer wood frame to keep up the litter, we would advise a hole to be made 2 feet wider than the frame all round, and 2 feet 6 inches deep, and then to run a 4½-inch wall all round up to the ground line. You can then make your bed for the frame, leaving for a lining a cavity all round, which can be filled at will or as required, and as it sinks it may be added to. Wood is too liable to decay to be used where bricks can with greater advantage be employed.

PRUNING (S. D. R.).—You should not lose any time in pruning the Gooseberry bushes, and all kinds of fruit trees should be pruned at once, and completed as soon as possible. The Gooseberries, having been much neglected, we presume are very full of wood, which we would advise you thinning well out, cutting all the side shoots on the branches left to within an inch of their base, and reducing the terminal shoot of each branch two-thirds its length. "Fruit Gardening for the Many" would suit you. You may have it free by post from our office if you send five postage stamps with your address.

PEACH TREES FOR SOUTH WALK (Idem).—Three good Peaches are Early York, Grosse Mignonne, and Barrington. In ordering the trees we should state that we required good, dwarf, fan-trained trees of the sorts named, and to be two or three years trained, clean, and healthy. We would advise fan-trained. We recommend short pruning—i.e., summer-pruning for the Peach. You may practise short pruning on all your old Peach trees with advantage, thinning out the old branches, and leaving the best of the young shoots for training in their place if necessary.

PLUMS AND PEARS (Idem).—Three good Plums; Jefferson, Cox's Golden Drop, and Green Gage. Two Pears; Marie Louise, and Glou Morceau. The old Plum trees we would not cut down, and you must not cut back the old spurs to within a short distance of the branch whence they proceed, unless you leave some young wood below the point where cut. We would thin the spurs and shorten them to some extent, leaving, however, a number close to the branch, and always a growing point or shoot, though short, below the pruning. If the trees are worn out replace them with others. You may cut back Currant bushes against a wall; but you must do it to where there is a young shoot, or young wood to furnish a shoot or shoots to train in place of the one removed.

FORMING A HOTBED OVER A FLUE (Subscriber).—Your chance of striking cuttings in pans placed over the flue would be small, but you might have a box made to place upon it, say 2 feet wide, 15 inches deep, and of any convenient length, and cover this with a glazed light, hinged at the back, so as to be easily raised. This box we have no doubt would answer well, indeed we have used such with good results. If the flue is hot at the part where the box is to be fixed, a fluestone should be placed beneath the latter; or if the box is too wide for the flue, you may place it upon slates or flags. At the bottom of the box, you may put from 1 to 6 inches of stones on pieces of bricks or crocks, and cover them with a thin layer of moss or cocoa-nut fibre, and then with 4 inches of soil or sand, or other loose materials wherein the cutting pots or pans can be plunged. In a day or two the box will be ready for the cuttings, and these being inserted the light may be closed, and the atmosphere of the box kept close and moist. With shade from bright sun you will have well-rooted cuttings of Verbena in a fortnight, and of bedding Pelargonium in from three weeks to a month. A little air should be given if necessary, to keep them from damping-off, and to regulate the temperature, which may be from 60° to 55°.

PRIMULAS (Idem).—Primulas should be kept moist, but they ought to require water before any is given, and then afford a good supply, and before they flag. As a rule they should be kept rather dry in winter, but

still the soil should be moist enough to promote a healthy slow growth. They succeed admirably in a cool airy greenhouse, having a night temperature of from 40° to 45° in winter, and should be kept near the glass, and not be watered overhead. A compost of one-half turfy light loam, one-fourth sandy peat, and one-fourth leaf mould, with one-sixth silver sand will grow them well. The leaves rotted from being frequently wetted in watering, and ultimately the plant from the same cause. They are liable to do so. You may prevent it to a considerable extent, by placing pieces of sandstone from the size of a hazel nut, up to that of a small walnut, upon the surface of the soil in which the plant is growing, and close to the collar, making them quite level with the rim of the pot, or slightly raising them above it.

ANTS IN GREENHOUSE (J. A. T.). You may drive them away by sprinkling guano over their haunts, or poison them with arsenic and honey, mixed in equal parts, and placed thinly in saucers. Care should be taken to keep the paste out of the reach of animals.

TREATMENT OF VINES IN POTS FOR FRUITING (Old Subscriber, Dublin).—You would see much in recent numbers, and in "Doings of the Last Week" as to the treatment necessary for fresh-potted trees when they are wanted to fruit the same season. In your case, and as you can give no artificial heat, we would advise you to let the Vines remain in the same 11-inch pots, and to set the pots, after enlarging the hole at the bottom, into larger pots, with rich compost at the bottom and between the pots, or if you did not mind moving the plants when in fruit, to set the pots in rich compost on the ground floor of the viney. You will thus gain all the advantage of rooting without the checks and risks that accompany it. Everything that fruits in pots does so best when the earth in the pot is full of roots. In the case of your Vines, make up your mind that if you obtain a good crop from them it will be the only crop they will bear. As these canes are strong and 6 feet long, we would not shorten them at all, but would fasten three or four sticks in the pot and twist the canes round them, which will cause the Vines to break more regularly. As there is no heat in the place, you can do little more than supply with rich waterings, give air as needed, thin the Grapes when set, and attend to air-giving, allowing them to have no sudden changes.

FRUITING YOUNG VINES (Idem).—We would not advise you to take any except a small bunch from Vines raised from eyes and planted out last autumn. If you were to plant out those you have now bought, we would advise the same caution to be exercised, or if you obtained more and planted them we would advise the same. You may fruit the strong Vines in 11-inch pots, and take what you can from them; but if they bear a crop we would not advise you to think of planting them out then for future service. You cannot take a crop from such a young cane, and yet make it of much service afterwards without a loss of time that would make a young Vine better in every way.

PLANTS FOR A WINDOW WITH A NORTHERN ASPECT (H. B. Leed).—Plants require much care to make them succeed in a northern aspect. Such bulbs as Snowdrops, Crocuses, and Scillas do well in winter and spring, and so do Chinese Primulas. All flowering plants will keep longer in bloom there, but it is not so easy to induce plants to come in bloom in a north window. We would recommend instead such sweet-scented plants as *Aloysia citrifolia*, and the sweet Oak-leaved Pelargonium, and variegated-leaved plants, as the variegated Cobaea, or the finer variegated Ivies, which are very beautiful.

TWELVE GREENHOUSE PLANTS TO FLOWER IN JUNE (A Constant Subscriber).—The following hard-wooded plants will bloom in June; their being in perfection on the 24th of that month will depend on the management:—*Boronia denticulata*, *B. serrulata*, *Crowea saligna*, *Pimelea Hendersonii* or *rosea*, *Illyria longifolia* or *Celsii*, *Polygala latifolia*, *Acanthia Drummondii*, *Daviesia latifolia*, *Cornus spiciosa* and others, *Bossia tenuifolia*, *Leschenaultia formosa*, and *Platylobium ovatum*.

SIX GREENHOUSE BULBS TO FLOWER IN JUNE (Idem).—For flowering in the end of June, not to speak of Gladioli, not properly bulbs, of the Colvilli and Blandias group, we may mention the following:—*Valloia purpurea*, *Bransvigia Josephine*, *Citium riparium*, *Serice versicolor*, *Pancratium canariense*, and *Cyrtanthus striatus*.

TWELVE GREENHOUSE FERNS (Idem).—*Adiantum capillus-Veneris*, *A. pedatum*, *Asplenium marinum*, *Blechnum hastatum*, *Cystopteris tenuis*, *Davallia canariensis*, *Gleichenia dicarpa*, *Hymenophyllum dilatatum*, *Lomaria Fraseri*, *Oncophyllum lucidum*, *Pteris serrulata*, and *Trichomanes radicans*. These are mostly small but beautiful.

ARNOTT'S STOVE (R. C.).—We do not quite understand your inquiry. An Arnott's stove of brick 2 feet 10 inches square, 3 feet 10 inches high, with a firebox of 10 inches square, and as much in depth, made with fire-bricks, would heat your house 45 feet by 12 sufficiently to keep out frost; but you speak of an Arnott's boiler. If the circumstances suited, you might have in the house a small Arnott's stove 2 feet 4 inches in height, and fed from the outside, and have fixed on the top one of Mr. Hughes's boilers 16 inches square, which is 4 inches deep at the sides, and 3 inches where concave in the middle, and with socket joints for 3-inch pipes. This or any small saddle boiler with a common furnace will heat your house; and to keep out frost you would need at least 40 feet of 3-inch pipes, and 50 more if you intended to force. By the Arnott's stove in the house, and the small flat boiler used by Mr. Rivers, you may heat the house without making stoveholes, &c. outside. The chief point is, that you must avoid above 18 inches in length of a horizontal smoke pipe.

PLANTING A FLOWER BED (C. B. M.).—You do not say what the size of your oval bed is, but the following will look well in double or single beds, beginning at the corner nearest to—*Crastium*, blue *Lolalia*, *Aurea* *tribunda*, *Calceolaria*, dwarf Scarlet *Polygonium*, such as Little David, *Cineraria maritima*, or *Centauria candidissima*, and the centre *Coleus*, *Amaranthus*, or *Perilla*. The *Coleus* will be best if it thrives in the place. A splendid bed at Woburn was filled with *Coleus* and edged with *Cineraria maritima*.

GRAFTING MANETTI ROSE STOCKS (Idem).—If we were to graft Manetti Stocks now, we would take them up out of the ground, cut the stems so low down that they would be under the soil in the pot, and graft before potting. The union would be sooner healed if the pot were set in a close place, or plunged in a very gentle hotbed. This will answer the third inquiry as to how much of the stock should be left above the pot, namely, as little as possible; and also the fourth inquiry, as to starting the stock in heat first, as what would be gained by doing so would be

lost by the greater trouble of grafting, so as to graft low enough after potting. If the plants had previously been in pots, then we would say, Prune back and excite the stocks gently before grafting. The shoots cut off will grow if inserted in the ground, made, say, 9 inches long and one bud left above the ground. The shoots of the Roses now in a cool greenhouse will do for grafting the Manetti stocks. See answers about Manetti Roses and stocks in page 142.

DESTROYING CRICKETS (*An Old Subscriber*).—Try phosphorus paste spread on slices of bread, laying these down in the house at night, and removing them in the morning; or mix 1oz. of arsenic, and a little ground aniseed and caraway seed, with half a pint of oatmeal. Lay the mixture on pieces of paper, but take care that no domestic animal shall touch it. It is a good plan to tempt the crickets with oatmeal and aromatics, without the arsenic, for a night or two, before using the poisoned mixture.

CATERPILLARS ON PELARGONIUMS (*W. B. M.*).—Your box arrived in a dilapidated state, and one of the three insects had escaped. The other two caterpillars are those of two distinct species of Noctuidæ, the large being that of a *Graphophora*. They should be looked for after dark with a light when they come out of their retreats underground, or among the leaves to feed.—*W.*

TREE ONION (*B. D. G.*).—We consider it quite worthless as compared with others of the same genus. You will be often deceived if you accept as a guide the work you name. No seed-man keeps the Tree Onion. It does not produce seed, but a bunch of very small bulbs on the top of a stem.

MATHEMATICS (*A Subscriber*).—Buy the Treatises in Chambers's "Educational Course." Loudon's "Self-instruction" contains some elementary information.

PEACH TREE PRUNING (*A Novice*).—The fruit is borne on the spurs. The leading shoot until it has attained its limit will not require stopping.

PREVENTING MOSS ON GARDEN WALLS (*Subscriber, E. P.*).—The best way to clear a wall of moss is to wash it with a strong brine made fully strong enough to support an egg on its end, but not to raise it. This should be applied to the wall with a brush, the trees being unnailed, drawn from the wall, and covered up if the buds have begun to swell, as is likely at this season. Whilst wet the wall should be dusted with fresh lime, making it quite white, and in two or three days it may have a coat of whitewash, subdued in colour by the addition of 1 lb. of flowers of sulphur to every gallon of whitewash, and 1 lb. of lamp black or soot to every ten gallons.

PROPAGATING THE ORIENTAL PLANE (*Idem*).—The best plants are those from seeds; but the plants are liable to be cut off by the frost, from the growths not being sufficiently ripened. They should be grown in a warm sheltered situation in dry ground, where the shoots will be better perfected, and able to withstand frost. Layers partake of the tree-like habit of the parent, and are more hardy than seedlings. Lime trees are increased by layers, and they make splendid trees, and so would the

Plane from layers, only our climate is in most localities too cold, and our summer too short for the full maturation of the wood. We would advise you to try grafting on the Sycamore.

AL FRESCO (*A. Trollope*).—We never state the real address of correspondents who adopt anonymous signatures. If you will send to us a letter undirected, with the six postage stamps requisite for the American postage, we will forward it. The same reply will apply to the query of "B. W. Royston," except that one postage stamp will suffice.

MOSS AND PLANTAIN ON CROQUET GROUND (*Melbourne*).—The best way to eradicate the plantain is to grub it up by the root, which may be done now when the ground is soft, or during showery weather. The production of moss is caused by the poorness of the soil, and the consequent poor growth of the grass. We would advise you to remove the plantains from now up to the close of March, and then to give a good dressing of very rotten manure or rich fine compost. After a heavy rain rake the surface well with an iron rake, and with a grass or daisy rake clear off the rough particles, if any, by the middle of April, and give a good rolling after sowing 4 lbs. Suckling Clover, 4 lbs. White Clover, 4 lbs. *Cynosurus cristatus*, 4 lbs. *Festuca duriuscula*, and 2 lbs. *Poa annularis*, in mixture, for one acre of ground. Any remaining roots of plantain may be destroyed by applying a drop of sulphuric acid from the end of a small stick to the heart or crown of each plant in dry weather.

POTTING PASSIFLORA BELLOTTI (*J. Bayley*).—Your plant having been so long in the same pot, we would not only repot it, but remove as much of the old soil as possible without destroying too many roots.

TORREYA PULCHERRIMA CULTURE (*Idem*).—You should have good well-rooted cuttings of this plant potted-off and established in pots before autumn. They should be kept on shelves near the glass and moderately dry during the winter. In spring they should be repeatedly shifted into larger pots as the pots become filled with roots, giving the last shift in June. The shoots may be stopped up to this time, and doing so will tend to make the plant bushy. With a light, airy situation, and a position near the glass, this plant flowers freely in autumn and winter. It requires the temperature of a stove, but will succeed in a vinery in summer.

COMBRETUM PURPUREUM PRUNING (*Idem*).—In pruning, the side shoots only should be cut back to within two or three good eyes of the main stem or shoot from which they take their rise.

MULCHING FRUIT TREES (*E. A. S.*).—The mulching put on in autumn should now, if of excessive thickness, be reduced by taking some of it away; but if it does not exceed 3 inches in thickness it may remain, and will gradually disappear. You are quite right; the less the ground is stirred close to the stems of fruit trees the better; but the spaces between, not being occupied with the roots of the trees, may be forked over with advantage. Never dig so as to interfere with fruit trees' roots.

NAMES OF PLANTS (*A. B.*).—*Polytrichum nodulatum*. (*R. D. Bolton*).—1, *Pteris serrulata*; 2, *Salicornia herbacea*. (*R. L.*).—*Crategus coccinea*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending February 18th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

LIGHT AND DARK BRAHMAS.

IN reply to "Y. B. A. Z.'s" letter, commenting on my remarks on Light and Dark Brahmas, I hope that I am not unreasonable in asking for fairness to be exercised, as it is absurd that cups should be offered to both varieties, but invariably won by the Dark.

That Dark Brahmas are larger I do not deny, but I do deny that they are handsomer; in fact, I do not know a prettier sight than a yard of twenty or thirty Light Brahmas in good feather and condition.

"Y. B. A. Z." seems to think that I ask for too much when I suggest separate cups for both varieties; but if the entries of Light increase as they have done of late years, I think committees will be well able to afford them a cup to themselves. If, however, they cannot afford a cup to both, let them offer the cup to the Dark, and increase the prizes to the Light; this would be much more satisfactory.

While on these subjects, I should like to know your opinion on trimming fowls' legs, &c. Is it fair to do so, or is it not? I know several exhibitors who openly admit that they do so, and if you expostulate with them they simply say, "Everybody does the same." But this appears to me most unsatisfactory; it should be either fair to get them up in the best way possible, or judges should disqualify for the least appear-

ance of trimming, and exhibitors discovered tampering with their birds should be excluded by the Society from further exhibitions. For myself I do not care which way it is to be, but I do hope before another season Mr. Hewitt and other eminent Judges will give us their opinions.—ALBERT O. WORTHINGTON, *Newton Park, Burton-on-Trent.*

FOUR-TOED HOUDANS.

I AM glad to see Mr. Schröder advocating the extinction of the "wretched fifth toe" in Houdans, and as in a work written by me, and very favourably noticed in your columns, I have contended (the first, I believe, who has done so), for the same result, I would like to add a word on the subject.

I feel quite certain that the fifth toe is the ultimate cause of the bumble foot of the Dorking. This is said to be caused by the bird flying from a high perch on to hard ground, or, according to some, by the great weight of the fowl; but many Brahmas are yet heavier, and still never have bumble foot, while a have seen many Dorkings never suffered to roost more than I foot above soft grass turf, and which never set foot on anything harder, in which the disease in its worse type has been developed.

Now, we profess to import and breed the Houdans, not so much as fancy birds (for even their plumage has not yet become uniform), but for their utility and hardness. With the latter point the extinction of the fifth toe is ultimately associated, and I venture to predict that just as soon as that fea-

ture shall become indelibly stamped upon the breed, the great bane of the Dorking race will begin to appear with it. At this period it may easily be bred out, and I am glad one so identified with the breed has had the courage to contend for its being done; and I ask any of our exhibitors who may share the opinion, to give weight to it with theirs, and we may then, perhaps, ask Mr. Hewitt and other judges to publish in your columns their permission that, concerning this point, all shall compete on equal terms.

I would like to ask Mr. Schröder if he has yet known any cases of real typical "bumble foot" in the Houdan breed?—NEMO.

MR. SCHRÖDER wants to do away with the fifth toe in Houdan fowls; I think the proposed reform comes too late. Pure Houdans from the yards of good breeders in the Houdan district breed so small a per-centage of four-toed chickens that the fifth toe must be considered a settled feature in this race of fowls.

Our poultry judges in insisting upon the fifth toe, have only followed the French standard of judging Houdans, made long before we in England knew much about these fowls. I have examined hundreds of them in the Houdan district without finding a single four-toed bird. I have imported a large number of them, and never received a four-toed one. In my last year's breeding I had only four chickens with four toes, and I traced them all to one hen, bought from a yard in the vicinity of Beauvais, quite out of the Houdan district. I have found this strain very impure. There are many of them in my neighbourhood, and they are as noted for the absence of the crest and muffling as for having mostly four toes. I believe that pure-bred Houdans will produce very few four-toed chickens, and should expect to find more or less an absence of muffling and crest in many four-toed birds—at least, such is my experience up to the present time.—F. B. HEALD, *White-moor, near Nottingham*.

CAMBRIDGE POULTRY SHOW.

THIS Show was remarkably well arranged, more especially when it is borne in mind it was the first effort of the acting Committee, whose desire to fulfil every duty was very obvious. The weather fortunately proved very favorable, and the Show was most successful. Although many of the birds exhibited bore evidence of the necessity of rest after the long season of exhibition, now so rapidly drawing to a close, the generality of those shown were in good condition, and many were remarkably so.

The Grey *Dorking* classes were very good; the *Game* classes scarcely less so, but in the latter, with the exception of few besides the winning pens, they were not well shown, the bulk being not of sound hard feather. In *Brabams*, the prizes were open to either Light or Dark-feathered ones and a good competition ensued, though not a single pen of the Light-feathered birds was entered. A few good pens of *Hamburghs* were shown, but the majority were not high-class specimens, the *Hamburgh* being a variety of fowls but little kept in the districts around Cambridge. Some really splendid specimens of *Spanish* fowls were shown, and were greatly admired. In *Bantams*, all kinds competing in one open class brought together about forty pens. The Game Bantams were very good, some very small Red Piles being particularly worthy of mention. The *Seabrights* were very indifferently represented. Some few nicely feathered pens of Pheasants seemed general favorites.

In *Ducks*, the Aylesbury were by far the best breed shown. The collection of *Pigeons* was uniformly good, so much so that many additional prizes might have been justly awarded had the funds permitted it. Many of the newly imported breeds in the Variety class of Pigeons were well shown, and were very unusual varieties.

In *Rabbits*, a sooty fawn-colored doe took the premium for weight, being 164 lbs, when brought to scale, and of that colour she was a truly handsome specimen. The longest-eared Rabbit measured 21 inches.

DORKINGS (Any variety).—First, Rev. C. Crosse, Cambridge. Second, J. Edgar, Osmanthorpe Hall, Newark. **CHICKENS**.—First, Mrs. Seamons, Aylesbury. Second, Rev. C. Crosse. Highly Commended, J. Haward, Great Blakenham; F. Parlett, Great Baddow; G. S. Hall, Ely.

GAME (Any variety).—First, W. B. Jeffries, Ipswich. Second, S. Matthews, Stowmarket. Highly Commended, J. Jekin, Eltham, Kent; H. Martin, Sculthorpe, Eckenham; W. Boyes, Beverley; S. Matthews; R. Hall. Commended, W. Dale, Weston-super-Mare; R. B. Stafford, Bedford. **CHICKENS**.—First and Second, S. Matthews. Highly Commended, J. Jekin. Commended, Rev. F. Watson, Messing, Kelvedon; W. Freeman, Cambridge; R. Hall.

Best Game Cock in Town or County of Cambridge.—Prize, R. Hall. **COCHIN-CHINA** (Any colour).—First, Mrs. J. Clarke, Bedford. Second, B. S. Lowndes. Highly Commended, B. S. Lowndes; W. Turner, jun., Ipswich; E. Shearman, Chelmsford; Mrs. Clarke; W. H. Tomlinson, Newark. Commended, F. G. Phillips, St. Leonards-on-Sea.

BRAMA POOTRA (Any colour).—First, Mrs. Seamons. Second, J. Dring, Gudeby Marsh, Long Sutton. Highly Commended, W. O. Quibell, Newark. Commended, Col. Stuart Wortley, London; Rev. E. G. Dawson, Otton, Belchamp, Sudbury; G. A. Shippey, Cambridge.

HAMBURGHS (Gold and Silver-pencilled).—First, H. Pickles, jun., Earby. Second, T. Coulson, Milton. Commended, C. Bayers; J. Clarke; W. H. Tomlinson.

HAMBURGHS (Gold and Silver-spangled).—First, Rev. F. Tearle, Gazeley, Newmarket. Second, H. Pickles, jun. Highly Commended, J. F. Leversidge, Newark. Commended, E. Hills, Ely.

SPANISH (Any colour).—First and Second, F. James. Highly Commended, H. Lingwood; W. B. Jeffries.

BANTAMS (Any variety).—First, W. B. Jeffries. Second, J. Parlett, Huntingdon. Highly Commended, Rev. F. Tearle; W. Dale, Weston-super-Mare; Mrs. J. Clarke; E. Toller, Little Carlton, Notts; W. H. Tomlinson. Commended, W. Eady, Milton; W. Mansfield, Cambridge; E. J. Drew, Weston-super-Mare; S. Rowley, Histon, Cambs; W. Moysie, King's Lynn, Norfolk.

ANY OTHER VARIETY.—First, A. S. Rae, Ely (Silver-spangled Polish). Second, Col. Stuart Wortley (Creve Coeur). Highly Commended, T. H. Windham, Salisbury (Creve Coeur); G. W. Boothby, Louth (Silver Poldans); J. Edgar (Houdans); W. O. Quibell (Houdans). Commended, W. Mansfield, Cambridge (Padua Chamois); J. Edgar (Creve Coeur); Mrs. J. Clark (White Minorca and Peravian); S. Stanley (Dorking Bantams).

PHEASANTS (Any variety).—First, Mrs. Sampter, Histon Hall (Silver). Second, H. Deuch, Ely (Tame). Commended, W. Freeman, Cambridge (Common).

DUCKS (Aylesbury).—First, Mrs. Seamons. Second, Rev. C. Crosse. Highly Commended, Mrs. J. Clarke; Rev. C. Crosse. Commended, Rev. W. J. Tibbrook.

DUCKS (Rouen).—First, H. Dowsett, Pleshey. Second, H. Frost, West Wrating Hall. Commended, J. F. Fetch, Cambridge.

PIGEONS.

TUMBLERS.—First, P. H. Jones, Fulham. Second, L. Wren, Lowestoft. Highly Commended, H. Yardley, Birmingham; J. Bradd, Cambridge.

POWTERS.—First, P. H. Jones. Second, H. Yardley. Highly Commended, P. H. Jones; F. Sale, Derby.

CARRIERS.—First, J. W. Addison, Cambridge. Second, L. Wren. Highly Commended, H. Yardley.

BARBS.—First, P. H. Jones. Second, J. W. Addison. Highly Commended, P. H. Jones; J. W. Addison; H. Yardley; J. Percival.

FANTAILS.—First and Second, H. Yardley. Highly Commended, G. S. Hall, Ely. Commended, J. Percival.

RUNTS.—First, T. D. Green, Saffron Walden. Second, H. Yardley. Highly Commended, T. D. Green; H. Yardley.

JACOBS.—First, P. H. Jones. Second, F. Sale. Highly Commended, H. Yardley.

ANY OTHER DISTINCT VARIETY.—First and Second, H. Yardley (Fairies, Ice Pigeons). Highly Commended, P. H. Jones (Dragons and Foreign Owls); J. W. Addison (Turbits); H. M. Hale, Croydon (Baldheads); F. Sale (Dragons). Commended, L. Wren (Trumpeters); J. Percival (Brussels).

RABBITS.—Length of Ear.—First, M. Millington, York, 21 inches. Second, J. Mellor, Cambridge, 19½ inches. Weight.—First, M. Millington, 16½ lbs. Second, W. Ellerby, 11½ lbs. *Any Breed*.—First, M. Millington (Fawn). Second, R. Wise, St. Ives (Silver Grey). Highly Commended, J. Allen; C. & R. Freeman (Himalayan); J. Mellor, Cambridge (Angola); G. Comins, Ely (Silver Grey).

CANARIES.

BELGIANS (Any variety except Pied).—First, R. D. Lenton, Cambridge. Second, G. J. Barnesby. Commended, E. Tyler, Cambridge; G. J. Barnesby.

BELGIAN (Pied).—Prize, G. J. Barnesby.

CINNAMON.—First, E. Tyler, Cambridge. Highly Commended, G. J. Barnesby.

NORWICH.—First, G. J. Barnesby. Second, W. B. Jeffries, Ipswich. Highly Commended, G. J. Barnesby. Commended, E. Tyler.

NORWICH (Pied).—First, G. J. Barnesby. Second, W. B. Jeffries. Highly Commended, E. Tyler.

YORKSHIRE.—First, G. J. Barnesby. Highly Commended and Commended, J. Mellor.

GOLDFINCH MULE.—First, G. J. Barnesby. Second, W. B. Jeffries. Highly Commended, G. J. Barnesby. Commended, E. Tyler.

CADE OF SIX CANARIES (Any variety).—First, Hon. Mrs. Neville, Cambridge. Second, G. J. Barnesby. Commended, E. Tyler.

BRITISH BIRDS.

GOLDFINCH.—First, E. Tyler. Second, R. Hall. Highly Commended, J. Mellor. Commended, W. Freeman, Cambridge; R. D. Lenton, Cambridge.

BULLFINCH.—First, R. Hall. Second, J. Mellor, Cambridge. Highly Commended, J. Baker, Cambridge; G. Bond.

NIGHTINGALE.—Prize, J. Mellor.

TURUSH.—Prize, J. B. Hopwood, Trinity College. Commended, H. Spinks.

BLACKBIRDS.—Prize, J. Mellor. Commended, J. B. Hopwood.

PARROT.—Prize, Rev. F. Tearle (King). Highly Commended, R. Callaby (Green).

Edward Hewitt, Esq., of Eden Cottage, Sparkbrook, near Birmingham, awarded the whole of the premiums for *Poultry*, *Pigeons*, and *Rabbits*; Mr. C. Pashler those for *Cage Birds*.

HALIFAX POULTRY SHOW.

THIS Show was held in the Odd Fellows' Hall, Halifax, on the 8th and 9th inst., and was well attended both by exhibitors and visitors. *Game*, *Game Bantams*, and *Brabams* were very good, and the *Hamburghs* were excellent. The Judge was R. Teebay, Esq., Fullwood, Preston.

SINGLE GAME COCK (Any variety).—First, J. Brough, Carlisle. Second, J. Wilson, Ovenden. Third, A. K. Briggs, Houshton Place, Bradford. Highly Commended, C. Chaloner, Chesterfield; E. Brough, Ball Hay Park, Leek; E. Akroyd, Bradford. Commended, J. T. Penland, Goos-bill, Bowling; F. J. Astbury, Prestwich; J. Mason, Kenwick Hill, Worcester.

SINGLE GAME HEN (Any variety).—First, J. Farrow, jun., Bardley Field, Kendal. Second, T. Suddick, Bradford. Third, E. Brough. Highly

Commended, J. Pickles, Mytholmroyd; E. Holland, Ovenden; E. Akroyd, Commended, J. Spencer, Queensbury.

GAME (Black-breasted and other Fals).—First and Cup for best pen of Game, E. Akroyd. Second, J. Fletcher, Stoneclough. Third, W. Boyes, Beverley. Highly Commended, J. Fletcher; J. Spencer. Commended, C. Chaloner; R. Hemmingsway, Shelf.

GAME (Any other variety).—First, J. Fletcher. Second, A. K. Briggs. Third, W. Boyes. Highly Commended, J. Brough. Commended, W. Dale, Weston-super-Mare; J. Thompson, Southworn.

SPANISH (Black).—First and Cup, J. Marchant, Halifax. Second, Hon. Miss Douglas Pennant, Penrhyn Castle, Bangor. Third, Messrs. W. and T. Pickard, Thorne, Leeds. Highly Commended, L. Blumiers, Horton, Bradford; J. Thresh, Bradford; J. Marchant. Commended, J. Thompson, Bingley.

COCHIN-CHINA.—First, T. Stretch, Ormskirk. Second, Hon. Miss Douglas Pennant. Third, H. Crossley, Broomfield, Halifax. Commended, Hon. Miss Douglas Pennant.

BRACHIA PECTORA.—First and Third, Hon. Miss Douglas Pennant. Second, J. Walker, Haya Park, Knaresborough. Highly Commended, W. H. King, Rochdale.

HAMBURGERS (Golden-spangled).—First, S. & R. Ashton, Mottram. Second, H. Pickles, jun., Darby, Skipton. Third, J. Pearson, Bradford. Highly Commended, W. A. Hyde, Hurst, Ashton-under-Lyme.

HAMBURGERS (Silver-spangled).—First, H. Robinson, Biddon, Leeds. Second and Highly Commended, J. Walker. Third, H. Pickles, jun. Commended, W. H. Sutcliffe, Wadsworth.

HAMBURGERS (Golden-pencilled).—First, J. Preston, Allerton, Bradford. Second and Third, H. Pickles, jun. Commended, J. Hollings, Bradford.

HAMBURGERS (Silver-pencilled).—First and Third, J. Walker. Second, J. Preston. Highly Commended, H. Pickles, jun.

GAME BANTAMS.—First, J. Hamber, Accrington. Second, E. A. Toder, Little Carlton, Newark. Third, J. Rhodes, Wakefield. Highly Commended, E. Blamires; G. Noble, Dewsbury; R. B. Riley, Ovenden. Commended, J. Rhodes, Southworn.

BANTAMS (Any other variety).—First, Messrs. Tonkin & Tuckey, Bristol. (Black). Second, T. Burgess, Brighton. Third, Rev. P. W. Storey, Daventry. (White Feather-legged). Highly Commended, J. Walker. (Scribble). R. B. Riley. Commended, Messrs. S. & R. Ashton (Black).

ANY OTHER VARIETY.—First, J. White, Northallerton (Grey Dorkings). Second, T. Burgess. Third, A. Tidwell, Ovenden (Blue Andalusians).

RABBITS.

SPANISH.—Medal, First, and Second, M. Millington, York (Fawn and Black and White Does). Highly Commended, A. H. Easton, Hull (Fawn and White Buck; M. Millington (Tortoiseshell Buck); W. Allison, Sheffield (Fawn Buck).

HIMALAYAN.—First, C. E. Marchant, Halifax. Second, F. L. Jones, Eatham, York.

ANGORA.—First, J. Alderson, Claremount, Halifax. Second, C. Rayson, Frestwich.

CRYSTAL PALACE BIRD SHOW.

We have much pleasure in again recording the annual exhibition of Canaries and British and foreign birds at the Crystal Palace, which opened on Saturday last, and will continue until Friday. The Show is being held in the new tropical portion of the Palace; but we question whether it would not have been advisable to have had it in the room in which it took place last year, as we fear that many of the little pets will return to their owner, somewhat the worse for their temporary change of residence.

The show of *Canaries* is quite up to the standard of previous shows, the most choice amongst which are the London Fancy and the Norwich and Jomque London Fancy, as well as the Lizards. The Goldfinch and Linnets Mules are most exquisitely beautiful and fine.

Among the *British* birds there are some most beautiful representatives of the Bullfinch and Goldfinch, and also of our Song Thrush; and in the Variety class are noticeable some extraordinary and most novel examples of the freaks of Nature, consisting of a most delicately coloured Bullfinch, a Goldfinch perfectly white, with the exception of a tinge of yellow on the wings and pink marking over the beak, and a cream-coloured Lark, and a white Sparrow.

The *Foreign* birds are not so well represented this year. There are some very beautiful Parrots, Cockatoos, and Paroquets. There is also a pair of Java Sparrows pure white, belonging to Mr. Hawkins, which attracted much attention. We likewise observed two most exquisite specimens of the Leadbeater Cockatoo, which deservedly obtained a special prize. The King Parrots and Paroquets are objects of great attraction, as also a covey of Partridges, exhibited by Mr. Stevens, of Netley Abbey, which was awarded a special prize.

The following is the list of awards:—

CANARIES.

NORWICH (Clear Yellow).—First and Third, Collinson & Hayden, Norwich. Second, W. Walter, Hyde Street, Winchester. Very Highly Commended, J. Bexson, Derby; J. Judd, Newington Butts; Collinson and Hayden; W. Walter. Highly Commended, Collinson & Hayden; R. Mackley, Norwich. Commended, J. Judd; Collinson & Hayden; W. Barwell, Southampton; G. Barrett, Peckham; R. Mackley; E. Coke, Derby.

NORWICH (Clear Buff).—First, E. Bennie, Rotten Row, Derby. Second, J. Bexson. Third, Collinson & Hayden. Very Highly Commended, W. Walter; J. Judd; Collinson & Hayden. Highly Commended, W. Walter; Collinson & Hayden; W. Barwell. Commended, R. Mackley; E. Coke; W. J. Toon, Kettering; J. Bexson; Collinson & Hayden; G. Tuckwood, Nottingham.

NORWICH (Evenly Marked or Variegated Yellow).—First and Second, Collinson & Hayden. Third, J. Judd. Very Highly Commended, W. Walter; J. Bexson; Collinson & Hayden; G. Tuckwood. Highly Commended, G. Moore, Northampton; Collinson & Hayden. Commended, G. Tuckwood.

NORWICH (Evenly Marked or Variegated Buff).—First and Second, J. Bexson. Third, W. Walter. Very Highly Commended, S. Tomes, North-

ampton; Collinson & Hayden. Highly Commended, J. Judd; Collinson and Hayden. Commended, W. Walter; R. Hayman, Middlesbrough-Tees.

NORWICH (Ticked or Unevenly Marked Yellow).—First, J. Bexson. Second, W. Walter. Very Highly Commended, J. Judd; Collinson and Hayden; H. Warrick, Norwich; W. Walter. Highly Commended, J. Bexson; Collinson & Hayden; W. Walter. Commended, Collinson and Hayden; W. Barwell; R. Mackley.

NORWICH (Ticked or Unevenly Marked Buff).—First, H. Warren. Second, Collinson & Hayden. Very Highly Commended, W. Walter; W. A. Blakston, Sunderland. Highly Commended, W. Walter; J. Bexson; Collinson & Hayden. Commended, J. Judd; Collinson & Hayden.

NORWICH (Variegated Crested Yellow).—First, G. E. Fryer, Clapham. Second and Third, Collinson & Hayden. Very Highly Commended, Collinson & Hayden. Highly Commended, G. Moore; Collinson & Hayden.

NORWICH (Variegated Crested Buff).—First, Collinson & Hayden. Second, G. Moore. Very Highly Commended, W. A. Blakston; Collinson and Hayden. Highly Commended, G. Moore; Collinson & Hayden. Commended, W. Walter; Collinson & Hayden; J. Judd.

BELGIAN (Clear Yellow).—First, S. Bunting, Derby. Second, H. Ashton, Frestwich. Very Highly Commended, E. Hawkins, Bear Street, Leicester Square; J. Bexson; W. Bulmer, jun., Stockton-on-Tees. Highly Commended, E. Hawkins; W. Bulmer, jun. Commended, E. Hawkins.

BELGIAN (Clear Buff).—First, S. Bunting. Second, H. Ashton. Very Highly Commended, E. Hawkins; W. Bulmer, jun. Highly Commended, J. Doel, Stockhouse; W. Bulmer, jun. Commended, J. Baxter, Newcastle-on-Tyne.

BELGIAN (Variegated or Ticked Yellow).—First, W. Bulmer, jun. Second, J. Hansen, Landport. Very Highly Commended, W. Bulmer, jun. Highly Commended, E. Hawkins.

BELGIAN (Variegated or Ticked Buff).—First, J. Baxter. Second, E. Hawkins. Very Highly Commended, H. Vine, East Coes; W. Bulmer, jun. Highly Commended, H. Vine; R. J. Troake, Bristol. Commended, J. Doel.

BELGIAN (Crested or any other Variety).—First, H. Ashton. Second, W. Walter. Commended, W. Walter.

JOQUE LONDON FANCY.—First, T. Mann, Cumberwell New Road. Second, J. Waller, Tchernacle Walk, Finsbury. Very Highly Commended, J. Waller. Highly Commended, J. Waller; W. Bradrick, Chisleigh. Commended, J. Waller; A. Ashton.

MELEY LONDON FANCY.—First, T. Mann. Second, J. Waller. Very Highly Commended, J. Waller. Highly Commended, J. Waller; H. Ashton.

LIZARD (Golden-spangled).—First, H. Ashton. Second and Third, G. Tuckwood. Very Highly Commended, J. Lumley, Derby; T. Fairbrass, Canterbury. Highly Commended, F. W. Fairbrass, Canterbury. Commended, F. W. Fairbrass; E. Hawkins.

LIZARD (Silver-spangled).—First, E. Bennie. Second, G. Tuckwood. Third, E. Hawkins. Very Highly Commended, J. Waller; F. W. Fairbrass; T. Smith, Coventry. Highly Commended, H. Vine; Collinson and Hayden. Commended, E. Hawkins.

JOQUE CANNON.—First and Second, H. Vine. Very Highly Commended, J. Wyke, Northampton; J. Waller; W. Walter, Finsbury; G. Moore. Highly Commended, J. St. John, Sunderland; G. Goulter, Northampton. Commended, G. Goulter; H. Ashton.

BUFF CANNON.—First, H. Ashton. Second, W. Walter. Very Highly Commended, G. Moore; G. Goulter. Highly Commended, G. Moore; S. Tomes. Commended, R. A. Simpson, Brixton.

ANY OTHER VARIETY.—First, S. Tomes. Second, G. Moore. Extra, W. Heap, Bradford. Very Highly Commended, H. Vine; H. Ashton; E. Hawkins. Highly Commended, J. Wynn; G. Moore; J. Baxter. Commended, W. Walter.

MULE (Yellow Goldfinch).—First, H. Ashton. Second, J. T. Tully, Monkwearmouth.

MULE (Buff Goldfinch).—First, J. T. Tully. Second, H. Ashton. Commended, J. T. Tully; H. Ashton.

MULE (Variegated Yellow Goldfinch).—First and Third, J. Doel. Second, J. T. Tully. Extra Second, H. Ashton. Very Highly Commended, F. E. Colman, Clapham; H. Ashton. Highly Commended, H. Peake, Dover; J. Doel.

MULE (Variegated Buff Goldfinch).—First and Second, J. Doel. Third, J. T. Tully. Very Highly Commended, T. Carrington, Derby; R. Hayman; H. Ashton. Highly Commended, G. Moore; J. T. Tully; G. Shiel, Sunderland; H. Ashton. Commended, W. Walter; G. Moore.

MULE (Dark Goldfinch).—First, W. Walter. Second, H. Vine. Very Highly Commended, H. Vine; S. Tomes; J. Baxter. Highly Commended, J. T. Tully. Commended, W. Walter; P. Flexney, Market Street, Caledonian Road.

MULE (Linnets).—First and Second, H. Ashton. Very Highly Commended, J. T. Tully.

MULE (Any other Variety).—First, W. Walter. Second, S. Tomes. Extra Second, E. Hawkins. Very Highly Commended, E. Winspear, Northampton; S. Tomes. Highly Commended, J. T. Tully; H. Ashton.

NORWICH (Six in one cage).—First and Second, W. Walter. Third, J. Judd. Very Highly Commended, W. Walter. Highly Commended, J. Judd.

BELGIAN (Six in one cage).—First and Third, E. Hawkins. Second, J. Jones, Manchester. Very Highly Commended, R. J. Troake. Highly Commended, J. Doel; W. Walter.

LIZARDS (Six Golden-spangled in one cage).—First, J. Judd. Second and Third, E. Hawkins.

LIZARDS (Six Silver-spangled in one cage).—First and Second, E. Hawkins.

MULES (Six Goldfinch in one cage).—First, H. Ashton. Second, J. T. Tully. Third, J. Doel. Very Highly Commended, W. Walter; J. T. Tully. Highly Commended, W. Heap.

MISCELLANEOUS.—First and Second, H. Ashton. Very Highly Commended, W. Walter; F. E. Colman; H. Ashton. Highly Commended, J. T. Tully.

BRITISH BIRDS.

BULLFINCH.—First, H. Vine. Second, J. Judd. Very Highly Commended, J. Wynn. Highly Commended, Mrs. T. Rose, Lougham Place, Northampton; D. Simmonds, Winchester; S. Hinds; E. Hawkins.

GOLDFINCH.—First, H. Vine. Extra, W. L. Chapman, Northampton. Third, Rev. H. C. Russell, Doncaster. Very Highly Commended, G. Moore. Highly Commended, J. Judd; J. Doel. Commended, W. Walter; J. Partridge, Peckham; A. Rettich, Brixton.

LINNET.—First, Highly Commended, and Commended, S. Hinds.
SKYLARK.—First and Very Highly Commended, J. Judd. Commended, S. Hinds.

WOODLARK.—First, J. Judd. Commended, C. Obermüller.
ROBIN.—Prize, J. Smith, Lower Norwood.
BLACKBIRD.—Prize, A. Isaacs, Prince's Street, Leicester Square. Highly Commended, W. Barnard, Anerley. Commended, L. Corti, Bath Street, City Road.

SONO THRUSH.—First, R. J. Baldwin, Northampton. Second, F. P. Cuddon, Croydon. Very Highly Commended, R. A. Simpson. Commended, W. Barnard.

STARLING.—Prize, J. Judd. Highly Commended, J. Judd; E. Hawkins; G. Munroe, Upper Norwood. Commended, W. Eicknell, Ebury Street, Belgravia.

MAGPIE.—Prize, A. Von Glehn, Sydenham.

ANY OTHER VARIETY.—First, J. Adams, Eastbourne, Sussex (White Goldfinch). Second and Third, E. Hawkins. Fourth, T. Carrington. Fifth, J. H. Oxley. Highly Commended, E. Hawkins (White Sparrow); Rev. H. C. Russell (White Pied Linnet).

BIRDS OF PASSAGE AND MIGRATORY BIRDS.

BLACKCAP.—Prize, C. Obermüller. Very Highly Commended, S. Hinds. Highly Commended, C. A. Bowdler.

NIGHTINGALE.—Prize, G. Miller, New North Road, Hoxton.

SISKIN OR ABERDEVINE.—Prize, W. Walter. Very Highly Commended, J. Judd. Highly Commended, H. Ashton; E. De Le Simmonds, Winchester. Commended, E. Wimpsey.

ANY OTHER VARIETY.—Prize, E. Hawkins (Waxed Chatterer). Very Highly Commended, E. Hawkins. Commended, W. Walter (Waxwing).

FOREIGN BIRDS.

COCKATOO (Lemon or Orange-crested).—First, M. George, Upper East Smithfield. Second, K. H. Douglas, Dalston. Very Highly Commended, J. Partridge.

COCKATOO (Leadbeater, or Rose-crested).—First and Second, A. Isaacs. Special, F. Ashley.

COCKATOO (Any other variety).—Prize, J. Judd. Highly Commended, A. Isaacs.

GREY PARROTS.—First, C. Thompson, Upper Norwood. Second, J. Judd.

LOVE BIRDS.—Prize, J. Judd. Highly Commended, E. Hawkins.

PARAKEETS (Australian Grass).—Prize, H. Vine. Very Highly Commended, J. Judd; E. Hawkins. Highly Commended, J. Judd; W. Walter; A. Isaacs.

PARAKEETS (Ring-necked or Bengal).—Prize, G. Hurs.

PARAKEETS (Rosehill).—Prize, J. Judd.

PARAKEETS (Pendants).—Prize, W. Walter. Commended, J. Jones.

PARAKEETS (Any other variety).—Prize, J. Judd.

KING PARROTS.—Prize, A. Isaacs. Very Highly Commended, J. Jones; J. Judd.

COCKATEALS.—Prize, Mrs. G. Rockitt. Very Highly Commended, J. Judd. Commended, A. Isaacs.

LORY (Any variety).—Prize, J. Judd.

SPARROWS (Diamond).—Prize, A. Isaacs. Highly Commended, W. Walter. Commended, S. Hinds.

SPARROWS (Coral-necked).—Prize, J. Judd. Very Highly Commended, A. Isaacs. Highly Commended, E. Hawkins.

SPARROWS (Java).—Prize, E. Hawkins. Very Highly Commended, W. Walter. Highly Commended, E. Hawkins.

INDIGO BLUE BIRDS.—Prize, E. Hawkins.

WAXBILLS (Any variety).—First, A. Isaacs. Second, W. Walter. Very Highly Commended, J. Judd. Highly Commended, E. Hawkins; A. Isaacs.

CARDINALS.—Prize, E. Hawkins. Very Highly Commended, E. Hawkins. **WIDAR BIRDS.**—Prize, W. Walter.

ANY OTHER VARIETY.—First and Third, E. Hawkins (White Java Sparrow). Second, H. Ashton (Scarlet Tanager). Very Highly Commended, W. Walter (Grenadier Bishop). Highly Commended, W. Walter (White-headed Manakin); S. Bunting (Saffron Finch); W. T. Jones (Senegal Canary); A. Isaacs (Black Manakins). Commended, E. Hawkins (Glossy Oriole).

GROUP OF PARTRIDGES (Cross between English and French).—Special Prize, J. S. Stevens.

JUDGES.—*Comities.*—Mr. T. Moore; Mr. A. Wilmore; Mr. G. J. Barnesby. *British and Foreign Birds.*—Mr. W. Goodwin.

PIGEONS—MATING WITH MEALY, &c.

I NOTICE with pleasure Mr. Heath's remarks in the Journal of the 23rd ult. on my notes on the book entitled "Pigeons," and I have no doubt that by means of such communications we shall by-and-by reach a real "standard of excellence."

In my experience in breeding and observing the breeds of Pouters, the greater number of Yellow birds bred from a Mealy on either the one side or the other have shown strongly defined bars. By this I do not mean to say that the bars are necessarily dark or solid in colour, but "strongly defined," or plainly marked. When this has not been the case many of the birds have been pale in colour, some of a dappled or clouded yellow, others having the edges of each or most of the feathers marked with a lighter shade, and, as a rule, showing indications of the bar. Thus it is that Mr. Heath's "three Red cocks, with scarcely any sign of a bar," do show it, I am led to presume, in a degree—perhaps in a very small degree, but the indications are there. A good judge, looking along the line of Yellow Pouters in one of our exhibitions, will seldom fail in pointing out birds bred from Mealties.

I trust it will be understood that I do not condemn the birds bred in this way; they are to my eye all beautiful, and many of them, without doubt, very handsome in form, and when the

bars are strong in colour they add a very pretty variety to the Yellow class. It is the rule for breeding Yellow Pied Pouters that I condemn, and more particularly when recommended as possessing an "advantage."

This is one of the points I was desirous of pressing upon the attention of my brethren in the fancy; for now that we have attained to size and length of feather, we must give to colour more attention. When a book of such pretensions as "Pigeons" is put into our hands, we naturally expect to find at least plain directions founded on past experience, and if perused by a fancier of little or no experience, he as naturally looks upon it as an unerring guide. Fortunately or unfortunately, I must not say which, I have been born a Pigeon-fancier, and I did feel annoyed at finding a book on our pastime so well "got up," setting forth rules of this kind.

As the question of matching colours is now raised, allow me to ask, Why breed for Yellows from Mealy at all? We want a rich solid yellow colour, without bars on the wing. This being the case, it seems folly to introduce the bar or any other objectionable mark. We can introduce such marks by one cross, the bars more particularly; but how many crosses will it require to breed those marks thoroughly out? The bar will appear every now and then for generations. A pure-bred solid Red is the colour of bird to match with a Yellow, and from Mr. Heath's remarks I feel sure he will agree with me in this. I have only seen one or two specimens of Mealties without bars, I think only one; they are very rare, and the reason is that the Mealy comes from the Blue Pied; it may have been a distant cross, but Blue is the origin. Hence a Mealy is the best colour to match with a Blue (if a cross of colour is required), as it tends to give that softness to the blue colour so much prized, and certainly most beautiful. To a fancier of Blues a Mealy bird is valuable, it being generally of very fine shape.

The Mealties Mr. Heath refers to as "without any bars at all," are, I suspect, what are properly called Sandies. They are of a reddish sandy colour, not of that soft solid tint of the Mealy proper. The feathers are streaked with a dull reddish sandy or blackish red sandy colour; if so, the proper name is Sandy. Birds of this colour are of mixed blood, principally Black, and a most valuable bird to breed with Black Pied; as a rule, they are handsome in form, and often very fine in limb.

The prescription Mr. Heath kindly gives for roup I shall try the first time my birds are affected with that dire disease, and report the result. The diseases of Pigeons might form of themselves a study; the causes seem almost unknown, and the cures very uncertain. I have had upwards of twenty young Pouters carried off in one season from roup and purging, perhaps the following year only one or two; some years the old birds only are affected, and in other seasons the whole collection seems to enjoy perfect health.

In reading over the pages of THE JOURNAL OF HORTICULTURE, teeming with interest to every admirer of Nature—a publication I find almost everywhere—I meet with articles on horticulture in every department, on singing birds, fowls, bees, and silkworms, and even on the insects and dust that prey on or disturb each or all of them. But what of the Pigeon fancy? So far it is undeveloped in the field of letters, for few come forward to give us their experience. A pastime full of interest, requiring as much art and care as any other, year by year gaining on the attention of the public, and yet it is left in the background. We must bestir ourselves.—J. HURD.

BREEDING YELLOW POUTER PIGEONS.

HAVING read with pleasure the letters upon matching Pouters for obtaining Yellow ones, I wish also to state the results of my long experience and success in breeding that rare colour, of which I have bred some of the best birds both for richness of colour and style.

To use the words of my friend, Mr. Huie, in breeding for Yellows we want a rich, solid, orange colour, not a light or pale colour, or streaked at the edge of the feather with white or a buff tinge. Mr. Huie says, that five minutes' consideration will bring us to the conclusion, that no bird showing a bar should be introduced to breed the desired orange colour, and I fully endorse that opinion.

For obtaining Yellows, nearly in every nest of young birds the first need is to have a rich-coloured Red cock bird, and as nearly of a blood colour as possible. Mate him with a Yellow hen as rich in colour as possible.

Next mate a Yellow cock bird, of course as near as possible to the desired orange colour, with a blood-red hen.

From the produce of these two pairs of birds, pick out for stock next year some of the best young birds of the rich blood-red colour.

Now, to the practical part of obtaining that orange colour. Pick out a cock and hen both of the rich Red and mate them, of course taking care that they are not brother and sister, but from the different pairs of birds. This will insure your obtaining Yellows of the desired orange hue, and not only so, but nearly all the young birds will be Yellow.

Never put two Yellows together, for if you do you will lose the desired colour.

I will on another occasion treat upon matching the other colours of Pouters, also upon style and leg.—H. SIMPSON, *Beckingham, Newark, Notts.*

ROUP AND CANKER IN PIGEONS.

PIGEON-FANCIERS will, no doubt, feel grateful to you for the kind facilities you offer to them in the last number but one of your valuable Journal.

I have read Mr. Huie's review of Mr. Tegetmeier's work on Pigeons with much satisfaction. I trust the book before us does not presume to be offered as an authority on the rearing, &c., of these beautiful birds. A work entitled on its own merits to rank as a standard work upon Pigeons is much wanted, and would be hailed with delight by the fancy; but something other than a compilation of extracts and quotations from former authors is wanted.

I am a little surprised that none of the great Scotch or Irish Pouter-fanciers has come forward in support of Mr. Huie in this controversy, "Matching for Colour, &c." Mr. Volkman has in your number of the 6th inst., given to the fancy a valuable article in favour of Mr. Huie; the suggestions therein contained fully meet the case, and if fanciers would only endeavour to follow out his ideas, we should, ere long, see a marked improvement in Pouters of all colours.

I am of Mr. Huie's opinion, that canker and roup are not infections. I speak from an experience of four years, during which time I have had only one case of the former disease which proved fatal to a young bird. Of the latter disease I have had many cases, more especially among young birds, and the majority of the attacks proved fatal. Last week I destroyed a cock Stomacher on account of his having become very much reduced from the effects of this disease. His hen is in perfect health, and so are their offspring, now one month old.

Two years ago roup proved most disastrous to my young birds, and after careful observation I came to the conclusion that the state of the weather, which was very damp, and a want of proper attention in feeding, accounted in a great measure for the spread of the disease. Last season I lost very few birds from roup, and none from 'canker,' and I feel convinced if birds are kept free from damp, and are otherwise properly cared for, that fanciers would have less frequently to lament the loss of promising birds. Perhaps Mr. Rose will kindly communicate to the fancy his recipe for the cure of roup.—A. B. BOYD, *Richmond Lodge, Trinity, Edinburgh.*

UNITING CONDEMNED BEES.

1860 was the worst honey year in my recollection. After bringing my bees from the moors, my study was not how to obtain honey from my hives, but how to put honey into them, and how to carry the greatest number of stocks through the winter at the least cost.

Having twelve hives in all, I selected six, which I considered would make the best keepers, then took the bees out of the six weaker hives, and put them into four of the keepers, leaving two undisturbed. I then gave all the honey taken from the condemned colonies to the keepers, with the view of securing more stocks in the following spring and at much less cost than by feeding them all separately. I was rewarded in spring by possessing three excellent stocks, which survived, although three died, whilst my neighbours for miles round lost nearly all. I have followed the same system ever since—that is, I take the bees out of my condemned hives and strengthen my weakest keepers with them. I do not think it any advantage to add bees to a strong hive.

I consider it unpractical to drive bees into an empty skep after the honey season is over in this district, the chance of their surviving the winter being too small to counterbalance the certain heavy cost of feeding. Having, therefore, in 1860, resolved to transfer all the bees I could from six hives to other

four hives, I thought it necessary to devise some plan a little quicker than the old-fashioned system of tying two hives together and tapping at them until the bees ascend into the top hive. My hives being 16 inches square outside, I made an apparatus of the same diameter, standing 3 feet 4 inches high, with an inclined plane of perforated zinc fixed in it half-way from the bottom. Standing the hive on the top I fold a sheet round the whole to confine the smoke, and rap the hive in order to disturb the bees. I then draw up a slide at the back of the apparatus and set fire to a quantity of paper prepared with a solution of saltpetre, previously put in the bottom of the apparatus, and shut down the slide. The smoke ascending through the zinc into the hive, the bees become powerless, fall on the zinc, and roll out through an aperture cut across the apparatus into a box placed against it, and made to fit close to, and above the apparatus, so as to keep the bees from ascending.

When I have smoked all the bees I can out of the hive, I detach the box containing the bees, carry them to the stock to which I intend to unite them, open the top, and take an empty hive with the top also open, turn it upside down on the crown of the fixed hive, turn the bees into it, cover them with a board, and then give the fixed hive a few puffs of smoke to stop fighting. When the stupefied bees have recovered and mixed with the others, I remove the empty box, and close the top of the hive.

I have constantly used this apparatus ever since 1860, and now my neighbours borrow it, and use it both for destroying bees, and preserving them. When sulphur is used to kill the bees the apparatus is much cleaner than a hole in the ground, and when it is used to preserve them the process is simple and quick, and few bees are destroyed, although a number always cling to the combs, to which I administer a dose of sulphur to put them out of pain.—GEO. WILSON, *Whalton.*

[No one who has once mastered the art of driving is likely ever to have recourse to fumigation. The difference, if there be a difference, in point of time, is very trifling, whilst we have proved by actual experiment that the vitality of bees is decidedly lowered by fumigation.]

OUR LETTER BOX.

POLISH FOWLS (*St. Edmunds*).—We do not consider that Polands are among the birds which best endure confinement. We believe much more is known now about poultry than there was fifteen years ago. This arises from the fact that there are ten times as many poultry-keepers as there were; and the necessity for having birds that will thrive under unfavourable circumstances has caused their habits and merits to be inquired into. The history of confinement is not a history of actual space, but of provision and management. It is possible by good catering to give in 15 feet square almost all that can be found in fifteen acres. Growing grass, fresh mould, animal life, light and air, lime grit—all these remedies counteract the confinement, and almost any fowls will do well; but Spanish, Cochins, Brahmas, will do well without them. Hence the difference. To these last Houdans may be added; they will thrive where their companions, Crève-Cœurs, will pine.

CAUSE AND CURE OF CROOKED COMBS (*Lemon Buff*).—We have always hope of a comb getting up if it has not fallen over from being too large and too weighty. A meat diet stimulates growth in the comb, and if withheld the effect is often visible in the gradual diminution and rising of the comb. Some use a strong solution of alum in water, with which they bathe the comb. Another plan is to take some silver wire, to tie the comb in the desired position, and to fix it through the thick fleshy base of it. The last is generally effectual. A less expensive plan is to cut narrow strips of diachylon plaster, and to strap it according to desire. It is desirable that Buff Cochins should be entirely buff all over. There are few without some mixture of mealy or white feathers. Both are less objectionable than black, but a little black in the tail or on the flights does not amount to a disqualification.

PACKAGE FOR EGGS (*H. C.*).—Eggs pack in a basket as well as in a box. If you prefer the latter, you must be guided by the size of the eggs; for instance, eight Spanish will take more room than twelve Hamburgs. The best material in which to pack them is dry moss. It keeps them in position, and does not move from jolting. In the ground oats, nothing must be taken away; that is the advantage, the whole must be ground sufficiently fine to mix readily in water.

FATTENING CHICKENS (*E. B.*).—October chickens should be fit to put up now to fatten, if they are for market. If for home consumption, they should be fat enough running about. Houdans bear confinement perfectly.

LINNET'S BEAK (*G.M.D.*).—File away the excessive length of the upper mandible.

LIME FOR FOWLS (*E. A. S.*).—As you cannot obtain bricklayers' rubbish, you may calcine oyster and other shells, or even bones, and scatter the white powder remaining after the burning about the poultry run. Powdered chalk, or powdered whitening would do even better, but not quicklime.

PORMICE (*C. A. J.*).—Nuts and acorns are the best food for them. The book you mention has not been published.

POULTRY BY RAIL (*Houset*).—Under the circumstances, we consider that you have no legal remedy.

BEE-FOOD—DIRECTIONS FOR MANAGEMENT (*L. R.*).—We always use burnt sugar and water in the proportion of three parts by weight of the former to two of the latter, and boiled a minute or two. You will find the best and simplest directions for management in the bee-keeper's calendar of "The Gardeners' Almanack," published at this office, price 1s., or free by post for fourteen stamps.

ERROR.—On page 143, line twenty-eight, for "may," read "many."

From observations taken near London during the last forty-one years, the average day temperature of the week is 48.6°; and its night temperature 33.1°. The greatest heat was 70°, on the 4th, 1860; and the lowest cold 14°, on the 3rd, 1862. The greatest fall of rain was 0.81 inch.

VINCA MAJOR ELEGANTISSIMA.

VINCA major elegantissima is one of the most useful and ornamental plants in cultivation; and so tenacious of life is this hardy trailer that no matter where it is planted, whether in the herbaceous border, the rockery, the shady shrubbery walk, or the bright and cheerful flower bed, it is equally healthy, and, what is more to the purpose, equally in its right place. In the last-named position no ornamental-foliaged plant is more useful, or can produce a more pleasing effect than this does when rightly treated. It looks well either as an edging or as a second row, for it is most accommodating in its habit of growth. The leaf, too, is one to which no fair objection can well be taken, possessing as it does that classical outline and richness of colour which are so generally admired and sought after, equalling in effect our most brilliant golden-leaved Pelargoniums.

Possessing such qualities as these, it is a matter of surprise that it is not more frequently met with; possibly the reason is that if it is not planted very early it does not look well the first season, and, therefore, as in most gardens a fresh arrangement of colours is required every

If the Vinca can be introduced into the second year's plan without being removed, it is found to have a richer and better effect than in the first season. I may add that my usual method of propagating this plant is to place a spare frame on a south border in the autumn, to work in a little sand with the soil, and to prick it full of cuttings. These are rooted by the following spring, when they are transplanted to the nursery, and after being stopped twice or thrice, in Yankee parlance, they are "let go."

MILKY WHITE POTATO.

My curiosity was aroused the other day on reading Messrs. Wheeler's advertisement, in which it is stated of this Potato, that "ripening in August, it continues in splendid condition for cooking all through the autumn, winter, and spring." I at once applied to this the maxim that "the proof of the pudding is in the eating," by having a few cooked, and certainly I was surprised and pleased with the result. The few cooked were as white and mealy as one could wish, having none of that closeness of texture which is almost invariably the case with all first and second early Potatoes when cooked at this season. Now, this is just what is wanted in Potatoes. A good cropper, free from blight, ripening early so as to be lifted before the autumn rains set in (so fatal as they are to the Potato),

1. Cloth of Gold Pelargonium.
2. Iresine Herbstii.

3. Vinca.
4. Lobelia speciosa.

5. Adonis Pelargonium.

season, by the time the Vinca has become established, and is ready to display most fully its attractions, it is removed.

The mode of treatment which I have found to succeed best is to take strong plants with at least a dozen shoots 9 inches or more in length; they are carefully taken up, retaining as much soil about the roots as possible, and are planted 1 foot apart in the beds. This is done as early in the autumn as the removal of the other plants from the beds will admit. In the following April the shoots are shortened to within 6 inches of their base, and pegged down close to the surface; they soon start into growth, breaking freely at every joint.

The young growth is stopped at the first joint, and this pinching has to be continued during the whole of the summer. The advantage of the pinching is found to be not only keeping the plants to the proper height, but also keeping up a constant succession of young shoots, the pure yellow of which is most effective.

In the past summer four parallelogram-shaped beds were planted in the manner represented above, and were much admired. The effect of the crimson Iresine placed between the two shades of yellow was very telling.

and continuing fit for table all through the winter, the Milky White must come into general cultivation, and I hope it will prove to be the forerunner of a race possessing qualities which appear to be the only effectual remedy for the blight.

Now, a word or two on cutting the haulm off Potatoes. Last summer I was strongly advised to cut off the haulm immediately on the appearance of spot in the leaf, and as I had seen this done by persons cultivating Potatoes more extensively than myself, I resolved to give it a trial. Accordingly I had a rather large breadth of the Red Apply (a very strong-growing kind, brought from Cornwall some fifteen or sixteen years ago), cut down to within 6 inches of the soil; after a week or two these Potatoes were taken up, and hardly a tuber was blighted, but the cutting appears to have materially affected the good cooking qualities of this hitherto excellent winter Potato, for instead of its usual mealy appearance when cooked, it is almost as close and "waxy" as an early kind. I am the more inclined to think this the case, because some White Rocks, of which the haulm was cut at a somewhat later period, have their cooking qualities affected in some mea-

sure, though not in so striking a manner as the former.—
EDWARD LUCKHURST, *Egerton House Gardens, Kent.*

HARDINESS OF CONIFERS.

As everything just now relating to the hardness of different kinds of Conifers is of interest, and being asked by a subscriber at Uttoxeter to state through *THE JOURNAL OF HORTICULTURE* the plants that stood the winter of 1867 here, I will now do so.

The following Conifers withstood the winter well—viz., *Cupressus Lawsoniana*, *C. argentea*, *C. gracilis*, and *C. erecta*; *Picea nobilis*, *P. Nordmanniana*, *P. lasiocarpa*, *P. pinsapo*, *P. magnifica*, which is almost identical with *Picea nobilis*; *Cryptomeria japonica*, *Retinospora lycopodioides*, *Araucaria imbricata*, *Cedrus deodara*, *Wellingtonia gigantea*, *Thuja Lobbi*, *Abies Albertiana*, and *A. Douglasii*. The last three grow rapidly; the *Thuja* grew between 4 and 5 feet last season.

Taxodium sempervirens, 36 feet high, lost 3 feet of its leader by weight of snow, but has started another, otherwise it was not injured. *Pinus insignis* shared the same fate as *Cupressus macrocarpa*.—E. CHITTY, *Outlands Park.*

CENTAUREA CANDIDISSIMA PROPAGATION.

THIS is generally admitted to be one of the best, if not the very best, of silvery or white-foliaged plants grown for bedding purposes at the present day; and though there are few gardens in the country where it is not to be found, still, as a rule, it is so in more limited numbers than its great beauty and utility entitle it to be. Placed in conjunction with flowering plants either in or out of doors it forms a striking contrast to them, while it has also the good quality of being effective from the day of planting till the end of the season. There are several reasons, however, to one or other of which may be mainly attributable the plant's not being more plentifully grown. There is, first, what many have found to be its difficulty of propagation. This I believe to be more imaginary than real. At certain seasons and under favourable circumstances this plant is quite as easy of propagation as most other bedding plants. I have on several occasions attempted to increase the stock of this *Centaurea* by putting in cuttings in September from strong plants growing in the flower garden; and although I was rather particular to have a small piece of "heel" attached to the cuttings, and to treat them afterwards in strict accordance with my ideas of their several requirements, I was wofully disappointed in the result, for only a very small per-centage of the number emitted roots, and of those that did so the majority felt an easy prey to damp during winter. This, to me, very galling circumstance might have been averted had some other treatment been pursued. I should like to know if success has crowned the efforts of any who may have attempted the propagation of this *Centaurea* so late as September, and, if so, by what treatment, as autumn is the season cuttings are to be had in the greatest abundance.

From repeated trials made at different seasons of the year, I have come to the conclusion that the spring and early summer months—say from March to July, are the best time to attempt to increase the plant. For this purpose it is necessary to have some old plants in pots; if several years old, all the better. If it is not intended to grow such in pots for another season, let the points be taken out of the strongest shoots; and if the plants be placed in just a very little heat a luxuriant crop of excellent shoots will soon be produced all down the stems. As soon as a number of these attain the length of 3 inches cut them off close to the stem, or, better, secure a small heel to each. With a sharp knife smooth the ends of the cutting, and remove carefully the larger and undermost leaves by cutting, not tearing, them off. Plant the cuttings either singly in small pots, or a number in larger ones, using soil of a light nature, with about half an inch of silver sand on the surface. Plunge the pots in a gentle bottom heat, where the top temperature may range from 60° to 70°; give no more moisture than is necessary to prevent flagging; and in two or three weeks, if due attention has been paid, there ought to be as many plants as there are cuttings put in.

As other young shoots become strong enough for cuttings sever their connection with the old plants, and treat similarly, until enough be secured, or the old plants cease to produce.

The strongest and earliest-struck plants will be ready for planting out by the end of May; the weaker and late-struck ones should be grown in pots all the year. Such will be excel-

lent for conservatory decoration during the winter months, and will make splendid plants for planting out of doors by the following May.

Another reason, as I think, which partly accounts for the comparative scarcity of this plant, is depending too much upon plants lifted from the ground in autumn for the following year's supply. This is a plant that does not generally succeed well when lifted. The woolly leaves and stems retain so much moisture, that it is with difficulty that a general decay by damping can be prevented. If the lifting of plants from the ground has to be resorted to, let it be done early in the autumn; endeavour to secure a ball to each, and pot carefully, as the roots are brittle and liable to breakage. If it is not found practicable to follow the advice given by Mr. Fish in a late number of the *Journal*—viz., to plunge such in bottom heat, let the majority of the leaves be cleanly cut off, so as to admit as much air as possible to the stems and necks of the plants, place in an airy position in a cool house, and give water only on the appearance of the stems becoming shrivelled.

The *Centaurea* will thrive well in any soil that is not too much exhausted.—J. A., *Wallhouse Gardens.*

The above list of sixty varieties contains the cream of all the Gladioli at present in cultivation—not, of course, including the novelties of the present season, and not yet tried in our country. The thirty marked with an asterisk are, as far as my experience goes, the most choice of all. It will be seen how very short we are of good straw-coloured and yellow flowers. I am longing, and indeed hoping, to see an irruption of yellows some day, something akin to that glorious burst of yellow Picotees and Carnations which emanated some seven or eight years ago from Mr. Smith.—J. F. LOMBARD, *Dublin.*

THE VIOLET FAMILY.

WE are beginning to see and hear something about *Viola lutea* and *montana* as bedders for the coming season. I have tried *Viola cornuta* Purple and *Maure Queen*, and have put quietly a patch of each in their proper place, the herbaceous border. My experience of them tells me that is the place for them. It may be that I have not hit upon the right treatment of these wonderful *Violas*, or it may be that our northern latitude is too much for their delicate constitution; at all events they are of no use here as bedders. I intend to try *Viola lutea* and *montana*. Should they serve me as the above-named have, I shall put them along with the others and let something else occupy their place.

Unassuming as the *Violas* are, yet they are worthy of far more extensive cultivation as border and rock plants than they generally receive. Take, for instance, *Viola palmata* with its beautifully-striped flowers as a rock and border plant in a sheltered situation. It is an acquisition to any collection. Erecta, growing 18 or 20 inches high, is another desirable border plant, to say nothing of obliqua, pedata, survis, pinnata, pennsylvanica, and that gem of *Violets*, striata. — M. H., *Acklam Hall, Middlesborough-on-Tees*.

ORNAMENTAL AND FLOWERING SHRUBS.

(Continued from page 112.)

The distance shrubs should be planted apart of course depends on their growth; if of dwarf, spreading habit, they ought to be planted twice their height apart; if neither erect nor diffuse, a distance equal to the height they attain will suffice; whilst those of pyramidal or conical habit may be a distance equal to half their ultimate height apart.

Evergreens are best planted during mild weather in autumn, and before the ground becomes very wet, and has declined much in temperature; indeed, the earlier it is done after the growth is complete the better, and I should in all cases prefer September for planting to any of the later months of the year, which are not unfrequently cold, wet, and unfavourable to rooting before severe weather sets in. Early in autumn and spring are the most eligible times for planting evergreen shrubs, and it is not certain which period is the better; only if planting is performed late in summer, or early in autumn, the necessity for watering is much less than when it is done in spring, a free use of the watering pot being necessary at the latter season. Winter planting is bad, even summer planting is more successful, there being a less percentage of failures by the latter than the former mode; indeed, with careful planting and judicious watering summer planting is safe, but unless the shrubs have been but recently transplanted, and the growth is complete, there is a danger of their partly losing their foliage; hence planting early in autumn is to be preferred. The greatest drawback to shrubs succeeding, is their losing the shelter they enjoy in nurseries from close planting; hence when planted late, or in winter, the plants are destroyed if the winter prove at all severe, whereas the same kind succeeds if planted at an earlier season, owing to its becoming hardened by exposure for a time before severe weather sets in.

Deciduous shrubs may be planted at any time from the fall of the leaf up to the time of their commencing growth; but the sooner it is done after the leaves commence falling in autumn the better is the prospect of a good growth in the following year.

Previous to planting the ground should be well and deeply trenched. It is the art of securing a good and speedy growth; besides, the shrubs withstand the drought of summer and the cold of winter much better than in ground very little prepared for their reception. It may not be desirable to bring up much of a bad subsoil to the surface, but it is well to remove some of it, and to loosen it as much as possible, so that water may enter it freely. Stirred ground is warmer, and though drier absorbs water more freely. In planting, a good-sized hole, large enough to admit the roots, should be made, and some good turfy loam enriched with an equal quantity of decayed vegetable matter, as tree leaves, will prove highly beneficial, a little being placed around and over the roots. Avoid deep planting; it only leads to an abundance of suckers, and makes their removal more difficult, besides retarding the growth of the plants. If the weather is dry, a good watering may be given at the time of planting, and it would materially accelerate fresh rooting and after-growth, if a mulching of partially decomposed leaves 2 or 3 inches thick were put round to the extent of the hole made for planting. The plants should be staked immediately after planting, and otherwise made secure against winds.

Shrubs that require a particular soil for their successful growth should have that peculiar to them, if not to the extent of the whole of the ground, at least to that of the hole made for planting. It is of little use planting such as bog plants in sandy soils; proper provision should be made for them, otherwise planting is only so much labour and expense thrown away.

Shrubs may be classed as—1st, Evergreen; 2nd, Deciduous; and 3rd, Those thriving in peat soil and consisting of evergreen and deciduous species. In endeavouring to describe some

of the most desirable, I shall be guided solely by my own observations, and I shall mention none but what I consider good and worthy of every care. Soil and climate exert a great influence on plants, and if I omit some shrubs, or give a wrong estimate of others, it is through their not succeeding with me, or from my not having had sufficient experience of them to warrant an opinion. I should be glad to learn from your readers or correspondents the names of any really good shrubs in addition to the following.

EVERGREEN SHRUBS.

ARCEA JAPONICA.—Leaves large, of a pale green, mottled and blotched with yellow. Growth spreading, foliage dense and compact. One of the best evergreen shrubs, thriving well under deciduous trees; indeed, for planting under these it has no equal. I have planted it where Yews, Hollies, and Laurels would not grow, and have found it succeed. I have also planted many hundreds, and never lost one during the summer from drought, which is one of the chief causes of the want of success which attends the planting of shrubs in plantations of large, full-grown, deciduous trees, the roots of the latter making the soil almost like dust during dry periods. The *Arcea* is also invaluable as enduring the smoky atmosphere of towns, of which I have no inconsiderable experience, and has no rival in that respect except the *Rhododendron*, which succeeds better than any other shrub in a smoky atmosphere.

The *Arcea* generally attains a height of from 4 to 6 feet, but may be seen of much larger proportions when growing under favourable circumstances. It does best in sheltered situations, but is very hardy, though it does not endure a very bleak position. It is increased by cuttings, which strike if put in during August or September in sandy soil in a warm situation; but does best when inserted in a cold frame at the end of August, or early in September, and kept close for a fortnight or so, afterwards giving air and drawing off the lights in showery weather. They are rather slow in rooting, especially in the open ground, and their growth is slow for the first two or three years. Layering is also a successful mode of propagation. It may be practised early in autumn, which is to be preferred, or in spring. These remarks apply to the old female *Arcea*, now *A. japonica maculata*, to distinguish it from recent introductions, two of the most important of which are—*Arcea japonica var. fraxinea* (Female Green leaved *Arcea*). Leaves green, contrasting well with the red berries which this plant produces in great profusion, on which account it is very desirable both for the garden and for cool greenhouse or conservatory decoration; and *Arcea japonica var. mascula* (Male *Arcea*), not particularly ornamental, but indispensable for the fertility of the female plants.

These may both be raised from the seed of berry-bearing plants, sown when ripe in pans or pots well drained, and filled with good light soil. Place them in gentle heat, pot the young plants when large enough, grow them in an airy greenhouse, and harden them off in a cold frame previous to planting out. Both kinds may also be increased by cuttings and layers in the same way as the old *Arcea*.

ARBUTUS UNEDO.—Leaves oblong, green, and shining; flowers white, drooping, and sweet-scented, produced in winter, succeeded by red berries having a resemblance to Strawberries, hence its name of the Strawberry Tree. The varieties known as *rubra* and *Croomii*, have reddish flowers. It is propagated by cuttings inserted in sandy soil in a cold frame at the end of summer, or when the wood is ripe or hardened; by layering in autumn or spring; and by seeds sown in heat, the seedlings being grown in a frame and hardened well off. It requires a sheltered situation, and in cold localities a south or west wall. Height, 10 to 15 feet.

ARBUTUS DRACONCE.—Flowers white, in March and April. Leaves shining, oblong. The tree attains from 10 to 15 feet in height, and has a smooth, reddish bark, which peels off annually. Seeds, layers, and grafting, *A. unedo* making a good stock. Needs protection when young, and in cold situations a wall.

ARALIA SEBOLDI.—Leaves large, fig-like, glossy, green, clothing the plant to the ground.

ARTEMISIA ABROTANUM.—Leaves small and finely divided. This is the Southernwood, cultivated on account of the fragrance of its foliage. Height 3 feet. Slips or cuttings in spring in a shady border, or shade for a few days from bright sun. Thrives best in a sandy soil. Not particularly ornamental.

BENTHAMIA FRAGIFERA.—Its flowers are its great attraction; they are large, yellow, produced in June, and succeeded by red fruit resembling a Strawberry. 10 feet. Requires a south or south-west wall. Seeds sown in heat, and cuttings of the half-ripened wood inserted in sandy soil on a hotbed.

BERBERIS AQUIFOLIUM.—Leaves pinnated, shining, bright green; flowers yellow, abundantly produced in April, succeeded by a profusion of bright purple berries that have a fine bloom. It will grow in partial shade, but not well in very shady positions. Very desirable. Seeds, layers, and suckers.

BERBERIS ANATA.—Leaves oblong, shining; flowers yellow, succeeded by red berries. A very desirable species of rapid growth. 6 to 10 feet. See *Isis* and *Layers*.

BERBERIS DARWINI.—Leaves small, shining, dark green; flowers yellow, in March and April, abundantly produced. Whether in or out of flower very beautiful, having a profusion of shining bluish purple berries, much relished by birds. Thrives well in partial shade.

3 to 6 feet. Seeds sown in spring in sandy soil in a sheltered situation, and layers.

Berberis fascicularis.—Leaves prickly and glaucous; flowers yellow, in dense racemes, succeeded by purple berries. Flowers in spring. 6 feet. It requires a wall in cold situations. Seeds and layers.

Berberis dulcis.—Leaves small, entire, deep green; flowers yellow, in spring. 6 feet. Grows well in shade, forming a handsome bush. Seeds and layers.

Berberis trifoliata and **Japonica** have bluish green leaves, consisting of three leaflets. Flowers yellow, in spring. Very fine, requiring a warm situation, good rich soil, and partial shade. Layers. 4 feet.

Bupleurum fruticosum.—Leaves glaucous, oblong; flowers small, yellow, in umbels, in July and August. 5 feet. Cuttings of half-ripened wood in sandy soil in a frame, layers in autumn, or seeds sown in spring in a gentle heat or on a warm border.

Buxus balearica (Minorca Box).—Leaves larger than the common Box, very ornamental, succeeding in partial shade. 15 feet.

Buxus sempervirens.—Many varieties differing only in the leaves being broad or narrow, plain or variegated. The taller sorts, growing from 8 to 15 feet high, thrive well in plantations not too much shaded. All bear cutting well, and make handsome globes or pyramids. There is a very dwarf variety much used for edgings, and there is, likewise, a narrow-leaved sort that makes a very good edging for walks in plantations, where it thrives better than the broad-leaved. Plants for plantations or shrubberies are best raised from seed, as they grow the straightest, tallest, and quickest. The seed should be sown in light soil when gathered. Cuttings succeed if put in during the autumn or spring, and all the kinds may be propagated by layers.

Cerastus laurocerasus (Laurel).—Height 15 feet. Well known as being the commonest and probably the most useful of evergreen shrubs. It succeeds in most soils, and under the shade of large trees, but not where the shade is very dense. It is well adapted for a screen, and may be used for the covering of banks, the shoots being pegged down, and cut-in in summer; in such situations the effect is good. There is a variety with narrow leaves, and also one with variegated leaves. The variety *colchica* has paler and more shining leaves, and is very handsome trained as a pyramid. Laurels will bear cutting to any extent. Cuttings of the shoots of the current year taken off at the end of September or early in October, with an inch or two of the preceding year's growth, succeed in an open situation if inserted two-thirds their length in the soil, and 3 inches asunder in rows 6 inches apart. The cuttings should have the base made smooth below a joint; it is immaterial whether the leaves are removed or not if the soil is made firm about them. The following autumn they will need to be planted out in rows 1 foot apart, and 6 inches from plant to plant. Seeds may be sown when the berries are ripe, and propagation may also be readily effected by layers.

Cerastus lusitanica (Portugal Laurel).—Bushy, spreading, and tall; dark green foliage; a most valuable evergreen succeeding in partial shade. Bears cutting well, and is very desirable as standards and pyramids for terrace and architectural gardens. Cuttings, seeds, and layers. Height 15 to 20 feet.

Chamaerops foliosa.—Leaves fern-like, much divided; flowers white, produced in great abundance. A very beautiful shrub.

(To be continued).

ANNUAL PRODUCE OF POTATOES.

Just two centuries ago the cultivation of the Potato was introduced into Lancashire, and just one century ago it was unknown to the rustics of Herefordshire, whilst the number of acres devoted to its growth in those counties were as follow during the last two years:—

	1866.	1867.		1866.	1867.
Lancashire	33,690	37,509	Herefordshire	2809	2508

The number of acres on which Potatoes were grown in various countries of Europe during those years were as follow:—

	1866.	1867.		1866.	1867.
England	311,151	289,611	Norway	—	67,500
Wales	44,266	45,077	Denmark	—	—
Scotland	143,426	157,529	proper	81,809	—
Ireland	1,059,353	1,001,545	Prussia	—	3,418,610
Jersey	1,308	2,062	Württemberg	169,045	—
Guernsey	677	789	Holland	—	273,380
Isle of Man	4,302	4,011	Austria	1,308,148	—
Sweden	—	350,000	United Sts.	—	964,614

GALVANISED WIRE AN INJURER OF PEACH TREES.

I WAS visiting a neighbour a few days ago, and was admiring a fine range of wall covered with galvanised wire, and planted with, as I thought from a distance, fine young healthy trees; but on close examination I found that the wood, wherever it was tied to the wire and came in contact with it, was dead for a few inches above and below the tie, and the other parts be-

tween the divisions of the wire were quite fresh-looking. I at once came to the conclusion that it was the wire that caused the evil, and I then thought that painting the wire might have some effect if tried.

It seems that at first the shoots have the appearance of being scorched, but that cannot be, as the destruction commences on the side next the wire and wall. To what do you attribute the mischief? The trees were well and properly planted, and the border is well drained and under practical hands.—RUSTIC.

[We believe that the cause of galvanised iron wire injuring the branches of wall trees trained to it is the friction caused by the wind against its hard and sharp surface. It was once suggested that the two metals united to form galvanised iron might be a weak galvanic battery, the constant action of which upon the branch might cause the wound, but we have seen the same injury where common iron wire was used as a trellis.—EDS.]

I HAVE for many years used galvanised wire trellises for Peach and Nectarine trees. By twisting the matting round the wires where the shoots are tied, they do not come in contact with the wires, and this prevents any injury to the shoots.—J. C.

OLD-FASHIONED PLANTS.

In reference to Mr. Williams's letter in your impression of the 6th inst., allow me to state that the only way of keeping the Purple and other so-called Rockets is by frequent transplanting and by constantly raising new plants.

I have preserved the Double Dark Purple and Double Light Purple Rockets now for many years on the worst of all soils for that purpose—an extremely cold, damp, wet clay—by these methods; as also the Double Red and Double Pink Ragged Robin, the Yellow Rocket, and what are more rare still, the Tall Double Scarlet and Double White Lychnis. The last-named I have never seen in England except in my own garden.

With regard to the propagation of the Dark and Light Purple and of the White Rockets, besides occasionally dividing the plants at the time of transplanting, I also raise a great many every year by simply cutting up the flowering stems into lengths having four or five eyes each, when the blossoms have gone off, and planting them by themselves as cuttings in a small bed of light made soil. Many of these throw out nice young shoots, and to this plan I mainly attribute my having so long been able to grow, and to help others in growing, these valuable perennials. If half the trouble were taken with these really interesting plants which is bestowed upon the ephemeral bedding-out class, the difficulties in keeping them would soon vanish.

Of all this family of plants the Double White Ragged Robin is, perhaps, the most delicate, and in its case I fear there is no safety but in potting a few young rooted offshoots from time to time in case of accidents. It is a gem amongst perennials.—W. J. MELLISH, Orston Vicarage, Notts.

Will you admit a few words of remonstrance from a very cruelly treated, ungratefully used, and persecuted race?

I am a poor old-fashioned plant, though as "every dog has its day," I've had mine; for I remember years ago how I used to be watched and watered, divided and subdivided; but now I suppose it is all up with me, unless you will allow some powerful voice to be raised in my behalf, for I have lived to see all my old friends and neighbours, who used to rejoice the heart in many a day gone by, ungratefully and even cruelly uprooted from the soil, to make room for those horrid "parvenus" and gay upstarts, and I fear my own time has also come.

This is the conversation I heard to-day:—

Master.—"John, I must have all these old-fashioned flowers removed; they don't suit the present system of gardening."

John.—"Where shall I plant them, sir?"

Master.—"Oh! plant them—let me see. Oh, John, after all you can throw them on the rubbish heap. I want nothing here but bedding plants, and I have no room for anything else."

John.—"Lor, sir, it seems a pity; we sha'n't have a single flower soon, that poor old master used to love so! I don't like these new-fangled ways."

And so you see, kind Editors, my doom is fixed, for these are the very words I heard this morning; and I thought directly

I'll write to those kind gentlemen, and tell them, and then, perhaps, before we are all exterminated, they will let some one say a word in behalf of a once-loved but now neglected—OLD-FASHIONED FLOWER.

RAISING ROSES FROM SEED.

Now, as Mr. Rivers tells us in his charming "Rose Guide"—now is the time for sowing Rose seeds—"in February or by the first week in March; the young plants will, perhaps, make their appearance in April or May." Mr. W. Paul in his "Rose Garden" advocates autumn sowing: "So soon as gathered let them be sown; they will then break through the ground in the following March, and, probably, some of the Autumnals will flower the first year." But how very little is done in England in the way of raising Roses—not because our climate is unsuitable, for some of our best Remontants (all honour to their originators), are English seedlings. What a comfort, too, it is when in the catalogues one meets with an English appellation, although this is not always a sure sign, such as sturdy John Hopper; Beauty of Waltham, our best red climber; the Tea Devonensis, which still holds its own against all comers; and our new friends, charming Princess Mary and not less charming Miss Ingram, who is just going to have her first season under Mr. Turner's auspices.

It is not a task of any great difficulty to raise seedling Roses. I do not mean to cross; this would require careful study of the great Rose authorities' instructions; but any one can collect the seed pods that every season form on some of the good Roses, and have them sown, and then there is a chance of something good resulting. The older and common Roses are hardly worth taking; but such as Général Jacqueminot, Jules Margottin, Géant des Batailles, Coupe d'Hébé, Prince Camille, and Safrano, ripen seed readily in our southern counties, and out of the vast quantity of seed that is allowed to waste every year, surely something might be raised that would be worth keeping and caring for. It would introduce, too, an interesting novelty into the Rose garden for each enthusiast to have his seed plot to show his friends, and excite their envy; and even the privates in our Rose army would then feel like Napoleon's veterans, that they, too, each carried a possible Maréchal Niel in their knapsack.

If the man is to be accounted a benefactor to his race who makes two blades of grass grow where but one grew before, how much more the originator of a really good Rose? And then the delight of naming it! "Glory of somewhere," of course; or, if white, what a delicate compliment to some fair lady! or, if red, to some red coat! or, perhaps, the happy owner prefers giving it a title; for it is pleasant to have people with handles to their names connected with us—say a Marquis at least—let us say the Marquis de Carabas! as poor Béranger sang—

"Chapeau bas! Chapeau bas!
Gloire au Marquis de Carabas!"

—A. C.

THE CLOCHE.

MUCH has been written on the subject of French and English gardening of late, and it seems to have been generally admitted that while in the broad features of horticulture we are far beyond the French, there are some points on which they are equally in advance of us, and that one of these points is the production of good winter salading. Now in this verdict I most heartily agree. While they are admirable theorists in every department of horticulture, good experimentalists, and careful manipulators, yet they can show nothing comparable to some of the grand achievements of practical gardening of which we are so justly proud. Their private gardens, whether those of the nobility or wealthier merchants, are not to be named with ours, while their nurseries are very far inferior. Take the very best of those about Paris, and what are they to some of our great metropolitan establishments? "A molehill to Olympus;"—badly kept, confined in space, and limited in their collections. The public gardens in Paris are certainly fine; but here the lavish expenditure of Emperor Haussmann, a greater man than Napoleon himself, supplies those sinews of war which are so grudgingly given in most private establishments abroad: and even here I question if we are not rapidly treading on their heels. They have nothing, not even the Parc de Monceaux, to compare with Mr. Gibson's wonderful achievement at Battersea; and if the improvements in the Regent's

Park and other public gardens go on, and the roughs allow them to remain, we may hope that we shall not be so very far behind them.

As regards the salading, go when you will to the Halles Centrales—(oh! that we had such a place instead of dear, dirty, dingy Covent Garden)—you are sure to see fine blanched Endive, splendid Lettuce, and at this season *barbe de capucin* and other salading. Why cannot we do the same? Mr. H. Knight, of Pontchartrain, has given in a contemporary an interesting account of the manner in which all this is done. But the groundwork and foundation of all is the *cloche*, or large bell-glass, of which you see hundreds in all the market gardens about Paris; and unfortunately we cannot manage the *cloche*. "Not manage it!" some one will say; "why, I thought we could do everything!" Well, it is just this—it will not pay. Full of zeal on the subject, and thinking it afforded a fair opportunity for some of our glass merchants to do a "stroke of business," I went the other day to the head of one of our leading firms—Mr. Phillips, of Bishopsgate Street, and had a talk with him about the *cloche*. He had tried it, and doubtless if it could be managed it would suit their purpose, as the liquid glass which remains in the bottom of the vessels after the finer material is run off would do, and it could be made by boys; but he assured me that the straw for packing to send away cost more than the *cloches* themselves; that if a person were living near the factory where he might carry them away, it might answer, but that it would never pay to have to pack them and send them any distance from the manufactory; so that I fear it is hopeless for us to expect to obtain them.

In the course of conversation Mr. Phillips also mentioned that he had failed in endeavouring to make a glass suitable for putting over bunches of Grapes on a wall. Here the difficulty, as I understood, was that in seeking to make it of the oval shape necessary, it was impossible to avoid making the base (if I may so call it) convex, and so prevent its lying close to the wall. Perhaps some one may suggest a means whereby this difficulty can be overcome.—D., *Doat*.

CATERPILLARS ON BEDDING PLANTS.

I SEE one of your correspondents (Mr. F. Fowler, page 124), has been troubled with caterpillars on his softwooded plants, and that he thinks they are the larvæ of the Cabbage Moth. It would be well if he could settle the question satisfactorily, as it is an interesting one. I have my doubts on the subject.

In common with many of your readers I have suffered from this caterpillar plague. Having this year more than five thousand seedling Pelargoniums of the bedding class, with almost an equal number of named varieties, I found it a serious business to have them all looked over plant by plant several times during the winter, to search for green caterpillars resembling in colour so closely the leaves on which they feed. Wishing to know to what moth I was indebted for this pest, I fed a number of the caterpillars, which varied in colour from green to brown. I had little doubt they would turn out the larvæ of the Yellow Underwing, as they exactly resembled the figures of that caterpillar in Curtis's "Farm Insects." Out of eight, varying from bright green to dark brown, six moths have come to perfection, and they are all Angle Shades Moths (*Phlogophora meticulosa*). The colour of the caterpillars depends, I think, on their age, the eldest being generally the darkest. Though I am quite satisfied all the caterpillars I have seen feeding on Pelargoniums are of this kind, another species may have troubled your correspondent.—J. R. PEARSON, *Chilwell*.

IMPROVED MELVILLE'S VARIEGATED BROCCOLI.

FOR winter decoration we find these varieties very valuable. Last spring we had a bed of them mixed with Hyacinths, and they were the admiration of all who saw them. At this season one of the bright-coloured heads, surrounded with a few hardy spring flowers, and a sprig or two of Box tree, make an excellent bouquet for table decoration.

We could have sent you a good many more varieties, but those now sent will give you some idea of the strain. We hope still further to improve these, and have had some really brilliant colours selected for seed.—STUART & NEIN, *Kelso*.

[We received about twenty specimens, each differing from the others, all beautifully curled, and varying in tints of creamy

white and pink up to the darkest green and purple. Kept dwarf, and used as Messrs. Stuart & Mein state, we have no doubt they are very decorative.—Ens.]

UPS AND DOWNS OF A ROSE.

I do not know from what ancient stock I came, it was a very old and honourable one I am sure—nor whether I was budded or grafted, or grew on my own roots, not that it can be of much importance, for I have heard one authority praise one way, and another authority equally good praise the other; so I do not believe it is of much consequence, though if I could have had any choice in the matter I would rather have been on my own roots. One matter I am very confident about, that is my appearance. I was very beautiful, I say it blushing, for one does not like to praise one's self; yet everybody who came near me said the same, or thought it; bright eyes looked brighter, and sad ones lost their sorrow when they gazed upon me.

I cannot tell you what colour I was, for some named me yellow, others buff, one said I was the colour of flaxen hair with plenty of golden threads in it. I was very vain, and spread out my dark green glossy leaves, so as to enhance to the utmost the charms of my blooms. I was greatly admired—called the most beautiful thing on the face of the earth, the queen of all flowers, worth hundreds, nay thousands of common cousins living out in the open borders, that sort of country cousins who put on their best attire just for a few midsummer days, then settle down into shabby greyness for the remainder of the year. I was lovely, as I heard a little maiden say every day of the long year, for even when I had no blooms to show I had soft delicate green leaves edged with carmine, and even my scattered petals were worth gathering up for the sake of their sweet perfume.

My place in the world was in a roadside cottage window, one of those old-fashioned windows that appear to be built on purpose to suit this cold sunless England of ours, for it had looks-out every way but to the north; so that whenever the sun shone, I could revel in its warmth. My house, but a few inches in circumference, was built of the poorest, commonest material—burnt clay, and even of the burning it had had too much, for there was black in patches where all should have been red. This little house, unworthy as I thought it, was well filled, every inch of space upstairs and down was occupied; sometimes in the hot summer I fancied I could have done with a larger place to live in. My prospect from this old window was into a country lane, a lane with high hedges, and under the shelter of which Primroses and Violets grew, making the early spring months fragrant with their sweetness, and when they were over out came the rambling Dog Rose—our relationship is very distant I assure you, I would deny it altogether if I could; yet I never used to see this poor Dog Rose, that I did not wish I had been something else. My ambitious choice would have been, to be a Climbing Devoniansis, growing up among the rafters, and sunning myself in the pure out-door air, and throwing forth my golden flowers—I like best to be called yellow—beyond the reach of envious eyes, or kleptomaniac fingers, or of that cruel instrument I dread still more, the gardener's knife.

My home surroundings were of the poorest kind, a stone flagged floor scoured over with another stone, then sanded over with red gravel ground up very fine, all very fresh and clean to look at, but, dear me! when the sweeping day came I was very thankful I could breathe without lungs. This sanded floor served for carpet, and hearth-rug, and druggit. A table, a few hard wooden chairs, and a chest of drawers made up the furniture; there was neither blind, nor curtain, nor shutters; all day long I could look out into the lane, and all night up at the stars.

My master was a worker in a quarry, and I was his pride and pleasure; much care he took of me. However tired he came home in the evenings I was never overlooked or forgotten, or thrust out of the way. All my wants were duly supplied; though never overfed, I could not imagine what hunger or thirst meant.

My food was not of the richest, nor prepared on the most scientific principles, yet it supplied all my needs, and gained the desired end, growth with strength and beauty. Simple as this food was, time and thought were necessary for its manipulation. Parings from a common, half soil and half dying grass roots, were mixed up with white sand; my master never would use the red, though he had large quantities close by, and for

the white he had to walk miles. This soil and sand were then incorporated with decayed tea leaves, not the proper material I have heard say, but then it was the best my master could obtain, and I was too full of vigorous growth to care much, if I had enough. Water, and without it none of our family can live long, came from a running brook; it was soft, and cool, and clear, and seemed to possess a renewing power as it was gently poured over me night and morning. I did not like it any the less because I knew the tadpoles had played in its shallows, and the swallows cooled their blue wings in it as they flitted over it. It was better in every way for me, than the hard spring water which used to chill and damp, but never refresh.

Yes, great store did my master set upon me, always giving me the best place, the lightest, driest, sunniest corner; never shutting me up alone in a heated smoky room, often for my good opening the window when he could better have done with it closed. But, though I had a merry pleasant life, it was not all sunshine, there would come days of rain and cold east wind, when the window could not be opened, and I had to live on as best I could. Then the enemy I hate most would be sure to make his appearance. The transparent-winged but yet deceitful green fly; how it came in used to puzzle me, it must have been on my master's jacket which he hung up close to my stand, but come in as it might, it was sure to find a speedy lodgement under one of my leaves, and was sure to choose the youngest and tenderest. In great terror lest my beauty should be spoiled, I was vain enough to care for my appearance. I rolled and twisted up my leaves, making myself as disagreeable as possible, in the vain hope the unwelcome guest would be driven to take its departure; yet nothing I could have done would have produced the desired effect if my master had not come to the rescue, with his pipe of tobacco, of which he was very fond. Luckily for me, darker and rougher the weather was, and more and more he smoked, until at last the little parasite not feeling well in a tainted atmosphere took its leave. But, I always came off the worse for its visits, however short they might be, for my twisted-up leaves never opened out again in a proper manner, and the rough usage I underwent to force back my good looks was often nearly my death. I was deluged over and over again with cold water thrown at me with great force, just like the bursting of a waterspout, then followed such scrubbing, and rubbing, and shaking of my little house, that I trembled lest its very foundations should be disturbed.

Putting all together, the world did not use me ill, and my master thought so much of me, and took so much care of me, that in return I could but be and do my best. So I grew and flourished, threw out strong shoots, and leaves, and flowers, and filled that old cottage window with a rare beauty, at which passers up and down the lane stood, and looked, and wondered.

One day in the full glory of my regal beauty I was carried away from my master's humble cottage. No word of warning was given me. I did not dream of the new honour to be conferred upon me, however much I might have desired it. Strong arms deposited me safely among the soft cushions of an open carriage, the amber lining of which was very trying to my wide-open blooms. I rocked about sadly, and many of my petals were shaken off as we jostled up the narrow lane. A little girl and a King Charles spaniel were my only companions, and they were too much engaged listening to the ponies' silver bells, which made music wherever they went, to think of me, or to trouble about the falling flowers, and I did not much care for the teasing and blowing of the wind, which with the sun and the hot dry dust injured me not a little; but then we cannot have everything, and the change was grand for me. It is not often the lowly born drive out in state, and I could not help wishing my German cousins might see me and be envious. What a miserable life it must be out in the hedgerows, winter and summer, exposed to every turn of the fickle weather.

When the drive came to an end, the same strong arms carried me into a large mansion, and placed me on a marble stand in a window of a room full of costly ornaments. This window opened out into a garden full of gay, scentless flowers, on which the midday sun was shining. I could see the brightness though I could not catch one of the beams, for blind and curtain were down, shading from the out-door light, lest in its strength it should enter and injure carpet, or pictures, or gilding. I thought of my nearly always open window at the cottage in the lane, and of the sanded floor which the quarryman's busy wife ground to dust all day beneath her heavy shoes; but then no sun or air could injure it, so the door was seldom shut from morning until night. Here, in this my new place, there was a still, close, as it were, used-up atmosphere, any-

thing but good for growth and life, and there might be dust, too, of a finer though not less subtle kind.

I was greatly admired—how they all thronged around me, father and mother, and little girl; how they counted up my fully open flowers and growing buds, and looked at me as though they had never seen a *Devoniensis* in bloom before.

My little red house looked poor and mean in the stately mansion, did not suit it, did not harmonise with anything about it; so it was to be taken away, or at least put out of sight. No better way suggested itself than that of slipping the ugly old house inside of a new and handsome one. A strange one was chosen as ever any poor Rose lived in, a kind of vase with red figures sprawling on a black ground, and into this I was put; but thrust down as much as they could thrust me, there was still a broad cornice of rough red to be seen; that, of course, would not do, so my house must be thrown away, and I must be removed into the new one. I had strong affections for the house from which I had not been absent for a long time, and every inch and corner of which was familiar to me; so the more they tried to lift me out, the more tenaciously I clung. They pulled and dragged, and thrust every way but the right one, to compel me to remove, and at last succeeded, but I was torn out, not taken out, and many of my valuable roots and much good soil were left behind. I was planted in the new house in a rough disorderly manner; no care was taken of the few roots left me, some were pulled away, others put in any way. Then proud of their work they bid me go on and flourish; live and be thankful they said, then left me sure that all would be well, left me in a beautiful new home, much too good for me, and yet not meeting any of my requirements, for it was a house without drainage, and without ventilation, and beyond the reach of the vivifying sunshine, for though my window looked to the south, blind and curtains and plate glass excluded all brightness. I lived, or rather existed, in a perpetual shade. At first I wondered at the long nights and the short days, and wished the sun could find its way in to me. I did my best to live, but found it hard to do so, for every effort I made was checked or hindered.

My new master did not understand my peculiar nature as my old one had done. My greatest sufferings came to me from his ignorance. I do not believe he cared for me much, for sometimes days would pass and I did not see him; he never came to give me anything I might need, or to feast his eyes upon my beauty. I was slowly pining away for the fresh air, and the sweet sunshine, but every inlet, every avenue was tightly closed up, as if poison and plague were floating in the warm breezes. My leaves appeared to lose their tissue, and my blooms their colour. Thinking I was going wrong my master pulled up the blind, and placed me close to the glass in the middle of an August day. That was too much for me, my hold of life was too weak to sustain me beneath its strong heat, so I drooped and drooped, and hung down more and more. Then, thinking I was thirsty, he flooded me with cold water—I think it must have been from an ice store—house and cellar and surrounding moat were all brim full; I was chilled, I thought I never should be warm again. A few of my buds slowly opened—they were but dull, faded malformations of my old self. Then I pushed out little green shoots to supply the place of the dead buds; but they never came to any size, for the aphid, that great enemy of mine, found them, and soon covered them thickly over. So there was nothing left but ruin and death, for relief could not come to me as it did in the cottage, because tobacco was a forbidden evil in the newly done-up drawing-room.

Then my master thought he would try if the out-door air would bring about any change for the better, for there was no doubt I was dying. So he chose a day with a keen wind blowing—a north-east wind, from which every living thing turns away in dread; and he stationed me just where its full force would beat upon me. He did not pause a moment to see how it would fare with me when left, but in great fear of the cold from which I had no escape, ran into the house, and I daresay soon forgot me. And no wonder, for the poorest hybrid that ever opened-out a few thin petals and called itself a Rose was fairer and better.

Next day my master came to look at me. My beautiful green leaves edged with carmine were soft and black with twenty-four hours of battering: the buds were all gone—there was no hope left for me. He had killed me though he knew it not; would not believe it, probably, if told. He stood over me in amazement, his hands thrust far down into his pockets. He was thinking of the piece of gold he left at the cottage only two

months before, or of the splendid Rose tree he had made his own by a dear purchase. And then with a "Well, it is over with it!" he pulled me right up, and with a great swing threw me to the rubbish heap; and taking up his showy vase, he carried it to the marble stand in the drawing-room in safety—MAUD.

ENTOMOLOGICAL SOCIETY'S MEETINGS.

THE Anniversary Meeting of this Society was held on the 27th January, when Sir John Lubbock retired from the chair, his period of office having expired; and Mr. H. W. Bates was elected President in his stead. An address was delivered by the former gentleman, giving an account of the progress of the science during the past year, and it was ordered to be printed and distributed among the members.

The February Meeting was held on the 3rd inst. at Burlington House, when the newly elected President took the chair, and returned thanks to the Society for his election, and nominated Sir John Lubbock and Messrs. W. Wilson Saunders and Stainton as Vice-Presidents for the ensuing year. Amongst the donations to the Society's library received since the last meeting were the publications of the Natural History Societies of Vienna and Bremen.

Mr. Frederick Bond exhibited a large swollen Coleopterous larva found by Mr. Harting within the shell of *Helix cricetorum*, the inhabitant of which it had devoured, and which was considered to be the larva of the female of *Drilus flavescens*; also the cast skins of a number of the larvæ of a species of *Dermestes*, which had not only devoured the bladder coverings of a number of jam pots, but had also eaten the jam. He also exhibited a very curious specimen of the large moth, *Lasiocampa Quercii*, the wings of which exhibited the colours and markings of both sexes mixed in a very irregular manner. He also communicated a notice of the attacks of a species of larva upon a living Elan antelope, into the horns of which it had burrowed. Mr. McLachlan also mentioned an instance in which the timbers of a vessel had been greatly burrowed into by the larvæ of a species of *Dermestes*; and Professor Westwood mentioned that the same insects, which are ordinarily animal-feeders, had greatly injured a cargo of cork.

Dr. Wallace exhibited specimens of the Japanese Silk Moth, *Bombyx Yama-mai* reared in this country, where they had deposited eggs; also the *B. Pernyi*, which feeds on Oak in China; and the South African *Pachypsa effusa*, which feeds on *Acacia*, from which an attempt was being made to obtain silk in that country; likewise the cocoons of the *Liquidambar* Moth from China, the larvæ of which are used for furnishing the silk gut used by fishermen, and of which the perfect moth is not yet known. He also made some observations on the progress of silk culture in this country, in South Africa, and in Australia.

Dr. Gray communicated a letter from Dr. George Bennett, of Sydney, containing extracts from Australian newspapers, giving an account of a surprising swarm of a moth known under the name of the *Bugong*, which is eagerly devoured by the natives, and which is a species of the genus *Agrotis*, *A. spina*. They had appeared in September in such vast swarms, that the houses were filled with them, and divine service in the churches had to be suspended. It was mentioned also as a remarkable fact, that the swarms were almost entirely composed of males. A swarm of butterflies of the Australian form of *Cynthia Cardui* had also been observed at sea three hundred miles from land, the vessel being literally covered with them.

Mr. Frederick Smith exhibited a number of interesting insects, chiefly Hymenopterous, from Brazil, accompanied by notes on their habits communicated by Mr. Peckholt, of Cantagallo. Amongst them were several species of honey Bees of the genus *Trigona*; and the writer had distinctly noticed that they swarmed like the European honey Bee, a fact not previously ascertained. A species of *Pepsis* provisions its cells with Spiders ten times its own size. *Trypoxylon albicans* builds a long cylindrical mud nest, which it also provisions with Spiders. A species of *Tripteta*, called the *Burna Fly*, deposits its eggs in the skin of various animals, as well as in the nostrils of persons whilst sleeping in exposed situations.

A beautiful species of *Oryssus* from the Gold Coast of Africa was exhibited by Mr. Swanzy, and the rare *Ajatura Ionia* from Asia Minor by Mr. Trimen; the latter insect had been doubtfully referred to the genera *Pyramis* and *Vanessa*. Letters were read from Mr. Hewitson and the President relative to the question of priority of the names published in the second part of the voyage of the "*Novara*" by Dr. Felder.

Mr. McLachlan communicated a monograph on the British species of *Nemoptera Planipennia*.

Mr. Daniel Hambury communicated some further notes on the economy of the Coffee Borer of Southern India supplied by Dr. Bidie, who had been appointed by the Madras Government Commissioner for investigating the ravages of the Borer in Madras and Mysore.

The Hon. T. De Grey exhibited *Opostoca Siliciella* and *Acidalia rubricata* from Norfolk, and *Hypercalia Christmanni* from Kent; and Lord Cawdor sent a specimen of *Phlebotus phalangoides* (Blackwall) from Stackpole Court, Pembrokeshire. A letter was also read from Dr. Signoret, of Paris, requesting specimens of different species of *Coccus*, especially males, for a monograph on that family of insects on which he is engaged. The specimens should be placed in tubes in

weak spirit, since when dried it was impossible, from their small size and soft delicate structure, to examine their forms with sufficient precision.

AMERICAN WELLS.

We have seen tried at Levallois, near Paris, a simple, ingenious, and expeditious method of finding water in the depths of the earth, and bringing it to the surface. It consists in striking vertically into the ground iron pipes, screwed to each other, till they meet a spring, at the top of which a pump is placed which sucks up the water. The process, which is simple, is thus described:—

The apparatus is composed of a number of iron pipes about 8 feet 2 inches long and the diameter inside about 2 inches, the sides about one-third of an inch thick, with a screw at each end, external on one and internal on the other, so as to screw them together, and thus to form one long tube the sides of which are air-tight; also an iron ram, *a* (fig. 1), of 8-stone weight, for driving the pipes into the ground, and a suction pump, *b* (fig. 2). The pipe which should first be put into the ground to open the way has a sharp, well-tempered steel point. Immediately above this steel point, about 2 feet of the sides of the pipe is pierced with a number of small holes for the purpose of letting the water inside the tube. First the pipe is sunk in the ground about 18 inches deep, the same as a bar of iron or a stake, then about 15 inches from the ground it is bound with a large iron pedestal, *c* (fig. 1), strongly secured with bolts; it is on

Fig. 1.

this pedestal that the blows of the ram are given to sink the pipe into the ground. The ram is an iron cylinder about 8-stone weight, with a round hole through the centre large enough to admit of its passing up and down the tube, which it surrounds, and rests on the pedestal; at the upper end of the tube there is an iron collar, *d*, to which two pulleys, *e*, are fastened, and by means of cords attached to the ram it is drawn up and let fall on the pedestal.

Such is the apparatus that we have seen working at Levallois; each blow of the ram falling on the pedestal drove the pipe about 2 inches into the ground; after eight or ten blows it was driven to the pedestal. Another pipe was then screwed on, the pedestal was raised about 18 inches and the iron collar and pulleys the same; the ram then commenced to strike to such an extent that in less than twenty-five minutes the pipes were driven more than 13 feet into the ground. A ball of lead suspended by a cord was then put into the pipes; by means of this sounding line it was discovered that there was about 3 feet

of water in the pipe; this quantity having been considered sufficient, a small suction pump was screwed to the top of the pipe, and after working it for a few seconds the water came dirty and muddy at first, then clear and limpid like a spring.

Such is the experiment that we saw at Levallois; it took place in the middle of a sand pit that was worked by a builder named Doucet; the ground appeared hard, with a clay bottom. A similar experiment took place a few days previously not far from there, upon the ground around the quarry. The pipes, at least 20 feet long, had to pass through a bed of flinty pebbles about 13 feet thick; the experiment lasted three hours; the pipes were then in their place, and the pump gave plenty of clear fresh water. The pipes can be drawn out of the ground by means of a simple wooden lever.

This process and the apparatus for putting it into practice are of American origin, and have been improved on by an Englishman named Norton, who has a patent for it. A Frenchman (Comte de la Fete) took an active part in the experiment.

Having read this you will say to yourself, as we did after seeing the experiment, What is the use of this process, and in what cases can it be applied? The indisputable merit of this invention is that in many instances water can be procured in a few moments and at very little cost. In all alluvial ground, in clayey or sandy soils, iron tubes can be put into the ground in a few hours and American wells made. They are easily made on low grounds and table lands. If steam tillage is one day established in the world, as we think it will be, the Norton pump will become an almost indispensable auxiliary to the steam apparatus. In a word, we believe in the practical utility of this operation, and have faith in this invention.—(*French Journal of Agriculture*.)

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

TRICHOCENTRUM ALBO-PURPUREUM (Purple and White *Trichocentrum*).—*Nat. ord.*, Orchidaceæ. *Lim.*, Gynandria Monandria. Native of the Rio Negro, in North Brazil. Petals maroon brown, tipped with yellow; lips white, with two purple blotches at the base.—(*Bot. Mag.*, t. 5688.)

BEGONIA SUTHERLANDI (Dr. Sutherland's Begonia).—*Nat. ord.*, Begoniaceæ. *Lim.*, Monœcia Polyandria. Native of the western mountains of Natal. Flowers coppery yellow. Stalks and veins of leaves crimson.—(*Ibid.*, t. 5689.)

HYPOXIS ELATA (Tall Hypoxis).—*Nat. ord.*, Hypoxidaceæ. *Lim.*, Hexandria Monogynia. Native of Natal. Flowers golden yellow.—(*Ibid.*, t. 5690.)

ODONTOGLOSSUM ALEXANDRE, var. TRIANE (Dr. Triana's Princess of Wales's *Odontoglossum*).—*Nat. ord.*, Orchidaceæ. *Lim.*, Gynandria Monandria. Native of the New Granadan Andes, near Bogota, at elevations of 7000 or 8000 feet. Sepals white, with one circular rosy spot in the centre; petals white; lip white, barred, and spotted with rose.—(*Ibid.*, t. 5691.)

STAPELIA PLANTII (Mr. Plant's *Stapelia*).—*Nat. ord.*, Asclepiadaceæ. *Lim.*, Pentandria Pentagynia. Native of Australia. Flowers purplish brown, barred transversely with yellow.—(*Ibid.*, t. 5692.)

HYPERICUM FATULUM (Spreading St. John's Wort).—*Nat. ord.*, Hypericaceæ. *Lim.*, Polyadelphia Polyandria. Native of Japan. Flowers large, and bright yellow.—(*Ibid.*, t. 5693.)

PELARGONIUMS.—"In *Emperor* we have what is in our opinion the premier flower of the season; for in regard to its size, its symmetry, its colouring, its outline, and its centre, it approaches as nearly as it seems possible to attain towards perfection, and it appears to have also the constitutional vigour which is necessary to secure the full development of these good qualities. The variety must be classed among the salmon rose sorts—a group which contains many other kinds of remarkable beauty. *Rob Roy* is quite distinct in colour, being one of the purplish rose group; it also is a flower of first-class properties, not so large as *Emperor*, but in regard to form and colouring equally perfect. Both sorts have gained first-class certificates at the hands of those lynx-eyed and severe critics—the London censors of flowers, which is a sufficient indication of their merits."—(*Florist and Pomologist*, 3 Series., i., 25.)

NOTES AND GLEANINGS.

THE ROYAL CALEDONIAN HORTICULTURAL SOCIETY is to hold three Exhibitions in the Music Hall, George Street, Edinburgh, during the present year. The first of these is to take place on

April 1st, the principal subjects being Hyacintha and other spring flowers, Camellias, Azaleas, and forced shrubs; but prizes are also offered for Pine Apples, Grapes, Strawberries, Apples, and Pears, and for Vegetables. Altogether there are sixty-three classes, in each of which two prizes are offered, and in some three. The second Show is fixed for the 10th of June, and is to consist of Stove and Greenhouse Plants, Roses, Pelargoniums, Heaths, and other flowering plants, for which there are twenty-three classes, whilst for Fruit and Vegetables there are nineteen classes. The two last-named have at the Autumn Show, to be held on the 2nd of September, thirty-five classes, whilst to Flowers twenty-five classes are allotted. There are, in addition, classes for amateurs and cottagers; and special prizes of £5, £3, and £2 are offered for six bunches of Grapes of not less than four varieties.

—THE 29th inst. is the last day on which entries can be received for the INTERNATIONAL HORTICULTURAL EXHIBITION AT GHEENT, and which is to be held there from March 29th to April 5th. Intending exhibitors have, therefore, no time to lose in sending notice of their intention and the amount of space which they will require to the Assistant Secretary, M. Edmond Clans, Rue Digne de Brabant, 20, Gand, Belgique. We may mention that the classes are about the same in number as at the London International Horticultural Exhibition of 1866, and consist of various classes for New Plants in and out of flower, Orchids, Palms, Cycads, Pandanads, Ferns, Lycopods, Arads, Caladiums, Marantads, Bromeliads, Stove and Greenhouse plants, both flowering and ornamental-foliaged, Bulbs, Trees, Shrubs, Fruits, and Vegetables, the last two, of course, much limited in the number of the classes by the season. Altogether, for the above and other subjects too numerous to mention in detail, there are 241 classes; and from the high position which the Belgians have taken at similar Exhibitions, we may expect a very fine display.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE increasing temperature of the atmosphere will now communicate warmth to the soil sufficient for the vegetation of all kitchen-garden seeds, therefore no fine day should be allowed to pass by without sowing some of the many sorts of seeds as follows:—*Brussels Sprouts*, sow thinly on beds of rich well-prepared soil, and cover the seeds evenly and lightly. *Cabbage*, sow the Covent Garden Superfine Early Dwarf, also the Dwarf Green Curled Savoy. Let the soil of the beds be well pulverised, scatter the seeds thinly and evenly, and cover them lightly with fine soil. *Cauliflower*, sow the Covent Garden Improved, or the Frogmore, on a slight hotbed, or under the shelter of glass. *Peas*, sow the Champion of England and Ne Plus Ultra, as the best early kinds of Wrinkled Marrows. *Parsley*, this of all vegetable seeds requires the longest time to vegetate, and therefore it should be one of the first sown. Slight hotbeds may yet be made to forward *Radishes*, *Carrots*, *Potatoes*, *Lettuces*, and *Cauliflowers*; also *Peas* and *Beans*, and some sweet *Herbs* if wanted early. If these auxiliary beds are hooped over and covered with mats they will answer well enough after this time.

FRUIT GARDEN.

Attend to the protection of the blossom of Apricot and Peach trees, and see that the recently planted standard fruit trees are staked, to prevent their being injured by high winds.

FLOWER GARDEN.

Many of the spring bulbs will now be showing bloom; it will, therefore, be necessary on a dry day to hoe the beds over, so as to freshen them up and make them a little neat. After the late frosts the lawn should be raked over with the daisy rake, to clean the grass of wormcasts or stones, and be rolled with a heavy roller at least once a-week. Where the grass is coarse it is a good plan to have it mown, cutting it close to the ground at this season; and where the herbage is thin, and does not cut well, a little Dutch Clover seed should be sown, and afterwards thinly covered with some rich soil. To those parts of the lawn which soon burn up in dry weather apply a dressing of wood ashes and soot, with a little sand, or, if more convenient, give a good soaking of liquid manure. Relay and repair Box edgings and grass verges, so as to have everything ready for trimming the walks as soon as the weather is favourable. Most of the hardy Roses being now pruned, the beds may receive their spring dressing. Nightsoil is said by Mr. Rivers to be the best manure to use, and if disinfected is not

objectionable; but if not disinfected it will be better to trust to the drainage of the dunghill, or to a dressing of guano. Plants that were much infested with green fly last season may be cleared of the eggs of that or any other insect by syringing them with water at a temperature of 160°, or by painting them over with lime, soot, and cow dung, mixed to the consistence of thick paint with strong soapuds. This is a certain remedy. The whole of the pleasure grounds should now have a regular cleaning—grass, gravel, borders, beds, and all, except, indeed, where alterations are going forward. Let all planting be finished as soon as possible, if other parts of the alterations have to stand still for a time.

GREENHOUSE AND CONSERVATORY.

Old-established specimens in the conservatory need not be potted for the next six weeks; old plants in general do not require to be so early potted as the young portion of the collection. The varieties of the Chinese Primrose are very useful from September to May, on account of their flowering so early in the autumn. A small quantity of the seeds may now be sown, and three more sowings of them made in April, May, and June will carry on the succession. Cuttings made now from forced Anne Beley Pink will be ready to be planted out by the end of April or beginning of May, as will also cuttings of other Pinks and Picotees now being forced. Be careful of bulbs when they have done flowering; the best mode of treating them is to take them out of the pots and plant them in a cold frame in any light soil; afterwards they come in useful for spring flowers in the borders. Those who want their Passion Flowers, Ipomaeas, and other strong-growing climbers to flower late in the season, when families return to their country seats, will now begin to prune their conservatory climbers. Of all ornamental plants, beautiful festoons of free-flowering climbers excite the greatest interest. From this time to the end of May some of the tribes in the greenhouse will want potting, beginning with seedlings and store plants. The greatest care is necessary in the selection of proper composts for different families. Good friable loam, fibrous turfy peat, leaf mould, and sand are the proper materials from which composts for all kinds of plants may easily be made; one-third peat, one-third leaf mould, and the other third of loam and sand, will make a suitable compost for young plants of most species in cultivation. Older plants will require the proportion of peat lessened, and that of the loam increased. Sandy peat alone is used for Heaths, Epacris, and the like; but the more robust of these and all the Chinese Azaleas, ought to have one-third leaf mould added to their compost. Two-thirds loam and one-third leaf mould, charcoal, and sand, form a good compost for Orange trees, Neriums, and many other strong woody plants. Charcoal and ground bones make the best drainage for all plants, and a greater quantity of them may be used in that way than of potsherds, thus making the drainage more efficient, and yielding a greater store of nutriment for the more active roots.

STOVE.

Orchids and other plants which have been kept in a temperature of 60° during winter, will require a gradual increase to 65°. Young or weak specimens of Orchids had better be kept in the coolest part of the house till all their buds or eyes are fairly in growth, otherwise the more forward buds may take the lead, and the rest may not start at all. Cuttings made now of the strong tops of all the showy Clerodendrons will make handsomer plants than their parents. They are very useful and showy as late summer and autumn plants for the conservatory. Continue to pot as the plants begin to grow.

FORCING PIT.

Gardenias and young Orange trees forced for their blossoms will now require a strong moist heat of 75°, with a bottom heat of from 80° to 90°. Many of our common border plants will force from this time if taken up with balls, potted carefully, and kept in the shade during the first week. Common Auriculas and Polyanthus will answer well in this way; leaf mould is the best material for them under this treatment. The evergreen Berberises are good plants for forcing, and they are much sweeter when they are forced. Paphnes do not like leaf mould so well as poor sandy loam, in which they may be easily forced. All the herbaceous Paeonies may be forced in pure sand, or any refuse from the potting bench, and they require no preparation beforehand.

PITS AND FRAMES.

The plants here, which hitherto have been kept quite dry, may now receive a gentle watering on some fine sunny morn-

ing, and be encouraged to grow a little. Give plenty of air in the daytime, but cover securely at night. Proceed with the potting of the autumn-struck plants, and the pricking-out of tender annuals, which should always be attended to before they become crowded in the seed pots, and encourage the plants afterwards in a close gentle heat until they are established in the new soil. Pot *Tigridia pavonia* and *conchiflora* in light turfy soil, putting two bulbs in a 18-sized pot, and placing them in a warm frame or forcing house until they begin to grow.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Peas.—We lately instanced how the open galvanised wire netting would protect from larger birds, but of course would not protect from rats and mice, for which trapping and other means must be resorted to. A new Pea seemed to have quite a run of intruders upon it. Very simple remedies are often effectual. One of our men, who has a garden, says the mice never burrow after his Peas, as he always sows some soot on the ground over the rows, and draws a spade gently over it. We have tried it with several rows, and not a single hole has been made in the course of a week. We presume that it will be effectual so long as the ammonia is given off strong. When other rows with stokehole ashes thrown over the surface have been visited, though little injured, not a single dig after a Pea has been made as yet in these sooted rows. No better surface-manuring could be afforded the Peas, and we hope, if not more generally known than it was to ourselves, that some sufferers may receive benefit from the soot-sprinkling. In many gardens now, the due preparation of the ground is not of more importance than the securing seeds and young plants after sowing or planting.

We have not previously grown Maclean's Little Gem Pea, but we are much pleased with its appearance, as it is coming on in pots. We tasted some of the Peas after germination had commenced, and, so far as we could judge, it seemed superior in flavour to any dwarf Pea suitable for pots. When grown in pots or in the open ground, it looks as if every Pea should have 2 or 3 inches. Our plants are now in 5-inch pots, three plants in each pot, under the glass of a frame, and by the time we shut up more closely our first orchard house we will transfer these Peas to 8-inch pots, rendering the soil firm at the sides. On the whole, we prefer sowing in the pots in which the Peas are to produce, but large pots take up much room, and we only had the seed lately, and wished to forward the Peas for early gathering. Room for three months to come is a serious matter with most of us, with whom every inch of glass must do its utmost. The being obliged to cram, keeps the inventive faculties ever on the stretch, and frequent movings involve a great amount of labour, which would be mostly saved were there a place for everything. Early vegetables must often now be obtained, and large flower gardens supplied, though in summer it would be difficult for a stranger to find where the plants came from.

Cucumbers.—Most of the plants intended for early spring work are under a frame on the top of a common hotbed, made with materials as lately detailed, with but little preparation, and the plants look well and strong, filling the pots with roots—after the second potting one plant in a pot. We have managed to clear a five-light pit supplied with hot water, have taken the earth in, and early next week, after having everything ready, we will turn the plants into the pit in a fine day, when the soil is nice and warm. Most likely we will try some in the seed box, and others as soon as we can obtain materials, and then there will be a race between the hot water and the frame. At an early period raising plants in the frame is the most economical, unless high temperature from hot water is required somewhere else. Our frame is very shallow, but that is no great disadvantage, for as the leaves of the Cucumber plants were coming too near the glass, we raised the frame the thickness of three bricks at the corners, just removing the banking-up to place a flat piece of board as a rest across the corners, and then the bricks were placed above the boards. Two bricks might have done, but we did not want to be troubled again, and it was as well that on the bright days at the end of the week the leaves should not be too near the glass. In all such raising it is of importance that sweet material should be packed at the back, and for at least 6 inches up the frame. That done, we banked firmly as high as the boards with what we could find handiest.

There is another advantage in raising the frame and thus keeping it banked outside with fermenting material. More top heat is thrown in through the boards, and the bottom heat in the bed is rendered more moderate. This helps to remedy the chief drawback in frames and pits heated by fermenting material only. In this bed there was no difficulty, by means of covering, in keeping the atmospheric heat up to 70°, and even much higher, at night if we wanted it; and in sunny days we could have just what temperature we liked best; but in very cold, stormy, sunless days, even with little or no air given, the atmospheric temperature would fall to 65°, or even lower. Now, here the hot water would so far have the advantage, that according to what was said the other week, we could easily have a temperature of from 60° to 65° at night, and up to 70° in a dull day. The old plan of increasing the atmospheric heat over a dung bed by sending heat by linings through the fermenting material, had a tendency to increase the drawback in two ways—first, by unduly increasing the bottom heat; and, secondly, by making the atmosphere when the bed was covered up at night warmer than during the day, if the day was dull and sunless. This prolonging at night of vegetation by heat—for it can hardly be called growth, as then there can be little or no solid addition—is fruitful of many evils which can be so far counteracted when we can obtain atmospheric heat, by banking-up outside, in a bed or pit, without that extra heat passing through the part where the roots are growing. By proportioning covering at night, and air-giving during the day, according to the weather, we can regulate a dung bed as we would one heated by hot water, so as always as a general rule to have the highest temperature when there is the most light.

Mushrooms.—Earthed-down a fresh piece of a Mushroom bed just as the previous bed was becoming like a sheet with small Mushrooms, and larger ones were still coming rather plentifully on older beds. In making a bed at this season we are forced to lose some of the strength of the dung in order to have it in a dry mellow state for the reception of the spawn. We pile the droppings and shortish litter in a heap, covered over with long litter, and if the material is so wet as not to become somewhat dry by this process, we cut some long litter short with a billhook, and mix it with the rest, and that, by causing it to heat, will dry it enough for our purpose. In making our shallow beds we have them as firm as possible, making firm again by beating after spawning, and on putting on from 1½ inch of fresh rather stiff soil we beat firmly again, and then, watering the surface, draw firmly a clean spade along it, so as to have the surface smooth. This secures the easy cleaning of the bed, and more especially when a little covering of hay and litter is used for maintaining an agreeable temperature. In large ridge beds out of doors the firmness, though important, is not so essential as in shallow beds in-doors.

We may here state that A tells us that, obtaining no Mushrooms, he gave his beds a good watering with water nearly at the boiling point, and in a few weeks had plenty of Mushrooms, but after one good gathering there were few more. B tells us that he followed the example of A, and has never had a Mushroom, and our opinion of the practice is asked. We reply that it must ever be looked upon as a bit-or-miss practice. We dislike to water much in winter if the air is moderately moist; or if not, we would have a slight sprinkling of hay on the bed in preference to much watering in the short dull days. When wanted we often prefer making a few holes and watering the bed back and front, instead of watering all the surface. We never use boiling water, except when troubled with woodlice, which we seldom are until the end of March or April. Then with a little dry hay we entice them to the back and front of the bed, and when we pour hot water there it sinks down, and does not extend far from the back or the front. Had we a bed cold, the spawn in dry material, and were sure none had begun running in the soil, we would not hesitate, if the soil was rather dry, to give it a good watering with water near the boiling point, because that would heat the soil, and the heat would decline to about 80° or 100° before it reached the dry material. If, however, the spawn was already running in the soil, and coming near the surface, we should expect it to be killed outright by such warm waterings. If we would be safe, then, we should keep from such scalding work. It is better to secure moderate moisture and an equable temperature by a slight covering of the beds. In heated houses it is more pleasant to see the beds bearing without any covering, but in that case it is easy to apply atmospheric moisture, or to give waterings judiciously when necessary, not using the water warmer than from 80° to 100°. In such a case a watering from manure

water made from old cow dung, deer dung, sheep dung, &c., often does wonders. We have never ventured on very hot water, except in the cases indicated, for the destruction of woodlice, and, unless in some extreme case, we should never think of so heating a bed, having often proved that though spawn will remain fresh a long time in a low temperature, it becomes weak, and perishes in a high temperature. From 90° to 100° may be considered the highest limit of safety.

To another correspondent, troubled with slugs and snails, and who proposes dusting with lime and watering with lime water, we would say, Never let your bed have quicklime either in a solid or liquid form. Nothing, not even the boiling water, will be more ruinous to the spawn and the young Mushrooms. Trap with greased cabbage leaves, brewers' grains, lured with a candle at night—anything or everything except the lime water; for we know of nothing more certain to spoil a bed, according to the strength and the time it is applied. If merely used on the surface before any Mushrooms appeared it might do no harm, but then it could do no good, as it would soon become as mild as a piece of chalk, and if it did no harm then to the Mushrooms it would as little inconvenience the slugs and snails.

ORNAMENTAL DEPARTMENT.

In fine days Ranunculuses and Anemones cannot be too soon planted; all manure for them should be placed a good depth from the roots. Carnations and Picotees in pots, if well established, should ere long be turned into their blooming pots. Three plants of a sort look well in a 12-inch pot. Where flowers without much dressing are required, one twisted wire support in the centre would do for the three. Nothing suits them better than fresh sandy loam, with about one-eighth part of sweet rotten hotbed dung. All the nostrums of half a score or more of ingredients for composts may now be numbered with the things that were. The finest Auriculas we ever saw were grown in sweet mellow loam, with a little very sweet, well-aired, leaf mould, and then in the spring they were top-dressed with sweet dry cow dung from two to three years old, and were watered with clear manure water as wanted. The Auriculas should still be protected from frosts and heavy rains, but have air back and front in all mild weather.

From the forcing pit bulbs are coming in; and shrubs, as Rhododendrons, Lilacs, Deutzias, and Roses, are adding their attractions. These should be all raised out of the bed and kept in the coldest end of the house before being taken to the conservatory, and they and bulbs taken thither, or to the dwelling house, should be moved before half of the flowers are open, that they may continue longer in bloom. Manure water, though clear, and bits of charcoal, will help bulbs in glasses.

Camellias in bloom want a considerable amount of water, and those finished blooming may as well have a little more heat in a vinery, or in a corner of the conservatory where they can be kept by themselves. Heaths now require more air in fine weather. Epacris will do with less until the long days come. Any plants of these, and of winter-flowering Heaths done blooming, should be kept stationary for a few weeks before pruning them back to make new wood for another year; the resting a little seems to suit them better than pruning them back at once. All young plants in the greenhouse and stove beginning fresh growth may now be repotted, especially when a little additional heat can be given to them.

Our window gardeners who kept their boxes or vases of Scarlet Pelargoniums in their spare room or garret, should now examine and give them a little water if very dry. Never mind if they are almost leafless if the main part of the shoots are sound. By March place them in the light; prune any that are decayed; give a little water at a time, making holes with a wire or pointed stick in the soil; and as soon as growth commences, and the leaves are the size of a shilling, remove what you can of the surface soil, and dress with equal parts of loam and rich compost, as sweet rotten dung. Thus managed, these plants, though never repotted, will bloom better and better every year—we cannot tell for how long; but we have seen some never turned out of their vases for nearly twenty years, and, if possible, the last summer was always the best.

Could we find room we would have a large number of cuttings of Verbenas, &c., inserted, and Pelargoniums potted. It must not be forgotten to sow Lobelia, Perilla, Mignonette, all tender annuals, especially of the Cockscomb tribes, and Amaranthus melancholicus in a gentle hotbed. The Mignonette to be hardened a little when an inch in height. This, if well tended, will cost little labour and come almost as soon into bloom as that sown in autumn and protected all the winter.

To have good rows of young Lobelias from seed it should be sown before the end of the month, and the earliest sowing pricked-off and kept in a slight hotbed until established. Pelargonias sown now with such help will make fine beds in the flower garden, and so will Verbenas, if any of our readers will be satisfied with a great variety of seedlings, instead of groups of one colour. Such plants as Antirrhinums, and Pansies English or Belgian, will bloom early in summer if thus assisted a little now, and that help may easily be obtained where stable dung or other fermenting material may be had, and there are leaves, fresh or half decomposed, or the remains of an old hotbed, to go to. Secure the heat and do not trouble much about its rankness if you can cover with from 8 to 12 inches of sweet material through which no noxious steams or gases will come; but make sure of that if you do not sweeten your fermenting material. With the best part of old hotbeds we are never long in want of a genial bottom heat when we can obtain a few loads of dung from the stableyard. When mowing commences in the pleasure ground there is still less difficulty, but there is more danger without carefully keeping down the steam, and grass itself soon flares out its heat, but it will yield a regular heat a long time when mixed with straw litter. When using, with a great saving of labour, such rough-and-ready materials, we say, Be sure that nothing but the heat comes up into the atmosphere of the place; and though we often find a covering of 6 inches quite sufficient, and have many tender plants in a similar bed under a frame now, we would advise beginners not to trust to less than 9 inches at first.

We cleared out the beds from two frames the other day that had not been quite bottomed for two years, and thus had a fine lot of rotten decomposed material for our flower beds; but we picked enough rather dry half-decomposed litter and leaves to make a covering over the fresh litter as brought from the stable, placed in the hole, trodden, watered, &c.; and the bed being thus covered, the heat which otherwise would have escaped in the process of fermentation will be brought at once into use, and after various crops and sundry turnings, the bed will probably end in being planted with Cucumbers and Melons. Such extemporised beds, where nothing better is to be obtained, will always be of use for securing produce early from the kitchen and flower garden. Some people now expect Celery at midsummer, and without the help of heat now it is impossible to have that and many other crops at all early.—R. F.

COVENT GARDEN MARKET.—FEBRUARY 26.

THERE is a slight improvement in business, and prices have an upward tendency for best articles in general consumption. French imports comprise Asparagus, Potatoes, Radishes, Artichokes, Lettuces, and Endive. Home-grown produce from the market gardens is largely supplied, and meets with a steady sale. Of Apples and Pears the quantity is limited. Retarded hothouse Grapes are very good.

TRADE CATALOGUES RECEIVED.

Sutton & Sons, Reading.—Suttons' Farm Seed List.—Supplymentary List of Flower and Vegetable Seeds.

Ballantyne & Son, Dalkeith.—*Catalogue of Forest and Ornamental Trees, &c.*

TO CORRESPONDENTS.

*. We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix upon the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

BOOKS (*Heaton Hall*).—When the volume on laying-out gardens is ready for publishing, which it will be in a few weeks, its title and price will be advertised. It contains so many plans, that the printing is delayed. (*C. J. D.*).—Mr. W. Paul's "Rose Garden," price 6s. 6d.

WILD FLOWERS (*T. J.*).—There will be various indexes, so that the plants can be at once referred to, for the plates are all numbered.

WIRE NET FOR PROTECTING GLASS ROOF (*W. D.*).—There are no notes on the subject. You can obtain wire net of any of the makers who advertise in our Journal. Unless small-meshed it would not protect the glass, and if small-meshed then it would shade too much.

DRESSING WHEAT WITH ARSENIC (*G. G.*).—Many farmers mix this poison with their seed wheat, with the intention of destroying the spores of the smut fungi that may be upon the grain. It is a dangerous practice, and we believe does not effect the desired purpose. A much more certain dressing is to wet the grain with strong brine, and then dust it thoroughly with lime.

GARDENERS' EXAMINATIONS (*Alpha*).—Two examinations are held annually. Any gardener may be examined. If you write to Mr. Richards, Assistant Secretary, South Kensington, he will send you full particulars.

GEONOMA MAGNIFICA FLOWERING (*H. Currie*).—We are informed by Mr. Smith, Curator of the Kew Gardens, that the *Geonoma magnifica* flowered in the stoves there last year, and is now showing flower again. He does not consider it at all a rare occurrence, as all that is wanted is to have the plant in good health, when it will flower almost continuously.

HOUSE SEWAGE FOR STRAWBERRIES (*One Who Wishes, &c.*).—As your soil is light and dry, cover the surface of the bed with cocoa-nut-fibre refuse an inch deep. You may apply the sewage, diluted with eight times its bulk of water, once a week, but not until the blooms of the Strawberry plants are open.

SMALL FARMING (*Yardley*).—If you forward thirteen postage stamps with your address, and order "How to Farm Two Acres Profitably," you will have a small book sent you free by post that will give you the information you need. It includes the management of cows and pigs, and if you have twenty acres you have only to multiply by ten every space of ground particularised.

MULCHING AND MANURING ROSES (*G. H. M.*).—"Roses like mulching at all times. If the mulching is not objected to as unsightly, it may be allowed to remain. Peruvian guano may be used lightly; one handful may be dissolved in a stable bucketful of water, and some of the liquid poured over the ground for an 18-inch radius round the stem. After the first series of flowers this may be practised with good effect, especially where the cultivation is not high, or where the staple of the soil is inferior."—*W. F. RADCLIFFE.*

ROUND PLANTS AT BATTERSEA PARK (*L.*).—Your query was answered in our Journal on January 30th, page 99.

COCCOLOBA PLATYCLADA.—*J. Bryan* wishes to know where this plant can be obtained.

PROTECTING PYRAMID PEAR TREE BLOSSOMS (*H. F. Foy*).—Your mode of protection will be excellent if the stakes be made firm, and the protecting material be put on so as not to touch the blossoms; it should be secured by string to the stakes. It will not be necessary to put on the covering until the blossoms are far advanced towards opening, then you may place it over the trees at night, and remove it in the morning if the day be fine; but if frosty it may remain on. When the weather is mild and fine the protection should be removed by day—indeed, it should only be used when the air is frosty. Protection will not be required after the trees are furnished with leaves. Of the materials you name, tiffany would be the best.

SALTING ASPARAGUS BEDS (*Halfpan*).—Salt is best given to Asparagus over the surface as a top-dressing. Employed in the making of the bed it would be merely thrown away. Bishop's New Long-podded Dwarf and Advance are excellent dwarf Peas for early crops, and Hairs' Dwarf Mammoth is very good for a main or late crop.

SELECT ACHIMENES (*Bellis*).—*Ambrosie Verschaffelt*, lilac white with radiating lines and carmine spots; *Baumanni hirsuta*, violet purple; *Margaretta*, white; *Longiflora major*, blue; *Sceptum*, vermilion, with rich markings; and *Carminata elegans*, rosy carmine.

SELECT GLOXINIAS (*Idem*).—*Robert Fortune*, rose belt and lips, tube white, finely mottled; *Cerulea variegata*, porcelain blue, streaked with white; *Striata maculata*, rosy salmon with white stripes; *Thomas Lohb*, pink-spotted tube, dark violet belt, margin blue; *Georgiana*, freckled; *Princess Alice*, reddish tube with spotted base, and crimson belt. From your description we should say the Rose is *Souvenir de Malmaison*. The Fern is *Pteris cretica albe-lineata*.

CINERARIA POTTINO (*C. W.*).—In potting it is not desirable to give large shifts, but to proceed gradually, and pot frequently. You may, however, place an established sucker in its blooming pot at once without giving two, three, or more shifts. We have tried both methods, and obtain the best plants from increasing the pot room as soon as the roots

become slightly matted round the sides of the pot. The same remarks apply to *Chrysanthemums*.

SOVING PEAS IN SMALL POTS (*A Constant Reader*).—Half a dozen Peas will be sufficient to put in a 60-sized pot. The heat must be very mild, and they should be kept near the glass, and be well hardened-off before planting out. You may sow three or four more Peas of *Tom Thumb* in a pot than of *Dickson's First and Best*. You may turn the plants out in the open ground when well hardened-off, so as to make a good row. A quart of *Dickson's First and Best* Peas will sow a row 33 yards long; a quart of *Tom Thumb*, 20 yards.

PEACH PRUNING (*Idem*).—You will find full directions in the book you name for the future management of the spurs. They will admit of the alternate shoot-cutting.

CHARCOAL (*H. C. J.*).—It may be used with advantage in the compost for all descriptions of greenhouse plants. It would benefit *Bignonia radicans*. Charcoal, however, is chiefly used in composts that have a tendency to become close, and especially for subjects having very delicate fibres, as *New Holland* plants and the generality of hardwooded plants.

PAUNING AYRSHIRE ROSES (*Kate*).—You may peg down the shoots now, cutting clean out any weak shoots, and the old if any, and limit pruning to merely taking off the ends of the shoots, for the less these Roses are pruned the better they bloom. Only the old wood and the very weak growths should be removed.

PLANTS IN AN OUT-DOOR FERNERY (*Idem*).—We would advise your leaving well alone. No plants whatever look well in a well-arranged and flourishing fernery. We have tried it, and find the plants introduced have an anything but pleasing effect. Nothing can add to the beauty of the graceful and delicate forms of the Ferns. The plan you propose for protecting the Ferns from frost will answer admirably, only make the protection strong to withstand wind. You could not employ anything better than tiffany.

MANURING ROSES WITH GUANO (*Idem*).—There is no advantage in applying so many kinds of manure at once; one sort will be quite sufficient. A sprinkling of guano round each tree in April and again in July, so as to make the surface yellow, stirring the ground lightly with a fork, will be sufficient. Bone dust is excellent for Roses. A couple of good handfuls may be scattered around each tree and neatly pointed-in with a fork. It may be applied now, and you may then give a dressing of guano during moist weather in May. Wood ashes may be applied in the same manner as bone dust, and probably a dealer in artificial manures would supply them to you.

SOUTH AUSTRALIAN SEEDS (*A Learner*).—Sandy loam, or loam and a little peat, will grow the *Mimosas*, or *Wattles*, from Australia, and a greenhouse or conservatory will suit them. From what you say we suspect you have some of the strong-growing *Acacias*, and they will require much room to do them justice.

THINNING FRUIT OF POT TREES (*Idem*).—You do not state the size of the Peach and other trees in 11-inch pots; but on an average you had better not take more than from twelve to eighteen fruit from them if you wish the fruit to be good. See what was said in "Doings of the Last Week" lately, and any specific information we shall be glad to supply. If in an orchard house, keep them as late in blooming as you can, and beware that the soil does not become too dry, or the blossoms may drop. Make sure that there is no stoppage to drainage, or the plants will suffer from stagnant moisture.

RAISING PLANTS FROM SEED IN BOXES (*D. Ryan*).—We think you will obtain the greater part of the desired information in "Window Gardening," which you have ordered. We do not think you will do much good in the back yard enclosed by walls and houses, and the space so small; but to give you a chance of succeeding, you should raise your plants in pots in your box that faces the south, and when tolerably well established plant them out in the yard. *Mignonette* and *Stocks* would do as well as anything, with *Nasturtiums* to climb up the wall. For your front box few plants would beat *Mignonette* and *Stocks*, and a fine display would be made with *Nemophila*, and *Nasturtiums* hanging over the sides, and *Canary plants* (*Tropaeolum canariense*) climbing up by the sides of the window; we would prefer it mingled with twining *Convolvulus* outside instead of inside the windows. You could have all these earlier by sowing in pots next month, and placing them in your box and covering with a square or two of glass. We do not approve of your proposed soil—that taken from an old shrubbery, an equal part of horse stable dung, and a third part of sawdust steeped in urine. We would not much like the sawdust, but would not dislike it so much if previously heated and decomposed with the dung. In all towns old shrubbery soil is the worst for such boxes; and we are sorry to say that the soil supplied from nurseries, which you say is so expensive, is very frequently not much better, being a mixture of old composts that have done work previously. To all amateurs who can by any means manage to do so, we advise obtaining a barrowful of soil from the sides of a highway, if nowhere else. If your boxes are shallow, say 7 or 8 inches deep, we would use but little of your prepared compost. If a foot or more in depth, and you turn the mixture over several times before using it, then you may fill the boxes one-half full, and procure better soil for the remainder. If you have a kitchen garden, or a flower plot that has been dug up roughly or ridged during the winter, then scraping-off as much from the surface in a dry sunny day as would do, would answer admirably; very likely better than what you could purchase. You had better have a few holes in the bottom of the boxes for drainage. Your sandstone over them will do very well, and so would oyster shells. A little moss over all would do well, and so would half an inch or an inch of chopped straw or litter before you place the soil in.

LIME RUBBISH (*J. Anderson*).—We should spread the mortar and plaster rubbish, after reducing it to powder, over the surface of the black loamy soil and dig it in.

NAMES OF PLANTS (*T. A. Allen*).—It is quite impossible for us to name plants from their seeds. (*H. T.*).—1, *Cornus mas*; 2, *Daphne mezereum*; 3, *Dentzia gracilis*; 4, *Heliotropium peruvianum* (garden variety); 5, *Jasminum nudiflorum*. (*A Constant Reader*).—Both specimens are varieties of *Selaginella Braunii*. (*A. H.*).—*Lenicera fruticosa* (?). (*A. B. C.*).—*Notholaena squamata*. (*W. M.*).—1, *Chilanthus farinosa*; 2, *Adiantum pubescens*; 3, *Pteris argyrea*; 4, *Asplenium marinum*; 5, *Pteris cretica*; 6, *Nephrodium molle*. (*Kate*).—*Pteris arguta*. (*H. Barton*).—*Iresine Herbistii*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

LIGHT AND DARK BRAHMA POOTRAS.

ALLOW me to offer a few remarks upon the criticisms on Light Brahmas, by our too-severe friends, "Y. B. A. Z.," and "Nemo," and which, if not replied to, would lead readers not well acquainted with this variety to think it, as "Y. B. A. Z.," says, a "degenerate" and unworthy race, and one which is most difficult to breed true to its characteristics, and rarely to be seen perfect. I wish to convince your readers there is no truth in the former assertion, and, as the last Birmingham Show proved, equally little truth in the latter notion. From the lengthened acquaintance I have had with Brahmas, and the share of success obtained since I have exhibited them, more particularly the Light, your readers will, doubtless, prefer the results of my experience to those of persons who have either not properly understood the breed, and, as a matter of course, have not been successful with it, or else with whom individual preference for the other colour overrules more mature considerations.

Your readers must first understand that more than one strain came into this country at or about the same time, and that our French neighbours received them also. Of these strains, Burnham's, the first sent to Her Majesty, seemed identical with that of Dr. Bennett—viz., of a "creamy tinge." That of Mr. Garbanatti, alluded to by "Y. B. A. Z.," was similar to the French strain, of a bluish white tinge, either much spotted about the rump and thighs, or streaked about the back; and Dr. Gwynne's (I believe Miss Watts and Mr. Tegetmeier had the same) of a French or bluish white, quite clear, and much the best in surface colour. The result of these different colours is much improvement in the present style of these fowls, for what was wanting in the shape of Dr. Gwynne's has been rectified by the Garbanatti and French birds, and the buff defective colouring of Burnham's, or Dr. Bennett's, has been rectified by the French also. Still these did not produce perfect birds; for the French and Garbanatti's had black tails, not in the slightest degree fringed with white, which they should be, and Dr. Bennett's had the defect of being too white down to the skin. The Americans of the present day breed them almost totally distinct, the head and face being quite different from our grouse-shaped head, having but small heads, and scarcely any wattle, good-shaped bodies, beautiful neck hackles, and fairly feathered legs. Thus we have quite as great a field for discussion upon colour in Light Brahmas as in the Dark. As the result of my experience, I predict that Light Brahmas with the surface colour of a pure clear bluish white, free from spots or streaks, will be the colour to stand its ground in the exhibition, and the ground colour for such must necessarily be grey. From thus considering the subject of colour, as a matter of necessity, in my opinion, we treat the variety as birds of colour, which "Y. B. A. Z." does not approve of, but I am compelled to think all exhibition fowls are judged by colour, and the more so the better.

Your readers will, doubtless, see a singular anomaly in "Nemo's" remarks, as applied to some one, and the staring fact of the winning pens having the dark grey ground and the blue white surface colour belonging to some said person who discards the before-mentioned colours. This is easy of explanation. "Nemo" evidently wrote without his notes, and his memory did not help him. From my own notes of the late Birmingham Show, I observe the following:—"COCKS.—First prize and cup, Mr. Dowsett's (not Mr. Pares's as 'Nemo'

observes). A good frame, coming three-year-old bird; of good colour, surface and ground; fairish neck hackle; not a good shape. COCKERELS.—First, second, and third, Mr. Pares. First prize, good shape, bad surface colour, being very much spotted, particularly on the thighs, and too clean-legged." When "Nemo" spoke of the remarks upon the colour of this cock, he should bear in mind when scanning the colour of the Dark, if they are too light, brown tinged, or badly marked, we quickly say they are a bad colour. The same applies here to the Light cock in question, he was splendidly shown, being absolutely without a dirty stain, or in the slightest degree disturbed in feather; but as I said then, we all agreed that his surface colour was the worst in the class, and I am so much astonished at "Nemo's" defence of Mr. Teebay's judgment of that and other Light cockerels, that I must beg of him to refer to No. 802 in the prize list, and 895 in the non-prize list, and compare notes. I placed the cockerels thus, and others present agreed—Mr. Pares's third-prize bird first; Mr. Herbert's highly commended second; and Mr. Pares's first-prize third; and in the value of these, first and third, Mr. Pares agreed with me, and was much astonished when he knew which of his birds had the first prize. From Mr. Pares's knowledge of Light Brahmas, I value his opinion as much as that of any person living, and quite agree with him upon the necessity of the surface colour being white (and free from spots for exhibiting), and the ground colour grey.—F. CROOK, *Vine Cottage, Forest Hill.*

P.S.—Referring to "Nemo's" remarks, that the Dark Brahmas are generally superior to the Light Brahmas, I shall have no objection to show twelve Light Brahma hens against any one person's twelve Dark Brahma hens for a fair amount, age and perfection of colouring and markings to be amongst the chief points in deciding. I omitted to mention before, that I was so far pleased with the first-prize Light cockerel, that I was anxious to become the purchaser of him, but Mr. Pares did not at that time feel inclined to part with him.—F. C.

In reply to "BENGAL," I regret to say I was not at Birmingham, and therefore have no means of judging, but I have seen within the last few months well-filled Light classes, as to numbers, but the quality with exceptional pens wretched. "Nemo" has in his letter explained the probable reason for this degeneration. I must, however, again repeat, and I do it with all the force that may yet attach to the title "WILTSHIRE RECTOR" first gave me, that of "Criticiser of Schedules," that the Light Brahma breeders in asking for a separate cup to both breeds, are asking that which they will never obtain except at a show with a strong Light Brahma bias. I mean, of course, as the gift of the Society; and supposing the petition granted, all the other varieties would expect equal favour. Brahma breeders have every reason to be satisfied with the position we have obtained for our pets. We have the two classes at most shows, and a single cock class; in fact, Brahmas, as a rule, receive now as fair treatment at the hands of schedule-framers, as they have any right to expect. Birmingham, perhaps, ought to offer them more money, still I repeat that generally they have fair treatment. I will give the Light Brahma breeders every credit, they have themselves very liberally made extra prizes for their favourites. This, I dare say, they will continue to do, and I for one shall be pleased to see a really better pen of Light birds winning the cup from the Dark.

I may here just explain an error in my former note on this subject. I said the Dark beat the Light birds amongst other points in length of leg. I should have said in shortness. This is most manifest to any unprejudiced person.

Thus far I had written, intending to quit a subject on which I feel all sides will never agree, when before breakfast this

morning I managed to devour, without preventing the digestion of that meal, Mr. Pares's reply. I have no objection to Mr. Pares's lance, especially with the courteous "button" that sheaths the point, neither with my lance have I any desire to unhorse the Light Brahmas. Before I can do this, they must get on horseback, or, in other words, win a cup; and if I am there to see, and they do not deserve it, well, then, lance in rest, "I'm in," as poor Artemus Ward would have said.

What I said in my former letter referred only to a cup offered to the best of the two breeds. I quite agree with the admirers of the Light birds, that they deserve equal money prizes with their darker brethren. The entries are nearly equal at the general run of shows, Birmingham, however, being markedly an exception; still the entries deserve equal prizes. Mr. Pares will, I think, bear me out, that I have often in these pages advocated the same prizes to be given to all classes, as secretaries can never tell which breed will pay best. This was not, I think, the point at issue, but the fact that the cups were always awarded to the Dark. Geese and Ducks are two different breeds; Dark and Light Brahmas two varieties of the same breed. It would be just in the former case to award a cup to the best specimens of their breed, whether Geese or Ducks; but when it is offered to the best pen amongst several varieties of the same breed, then, other points being equal, surely it ought to be awarded to the pen showing the best general characteristics of the breed—for instance, in Brahmas, size, depth of chest, breadth, shortness of leg, heaviness of leg-feathering and fluff, comb, &c. All these points ought to be as good in the Light birds as in the Dark. Mr. Pares, Mr. Worthington, Mr. Crook, and others, must forgive me, but in all these points, the distinctive points, in fact, that mark a good Brahma, whether Light or Dark, the latter appear to me by far the better. Supposing these points equal in two pens, then the decision would hinge on the best-coloured birds, and then the characteristics of each variety, as to colour, &c., would turn the scale.

Mr. Pares seems to consider he has quite unhorsed me by the "blue" and "green" idea; as it was always allowable for the unhorsed champion, who, possibly like "Y. B. A. Z.," did not know when he was beaten, to renew the battle on foot, so I reply "Blue" and "green" are but qualities of a certain something. Suppose it cloth, then if the material were equally good, the choice hangs on the colour according to the fancy; but if the material were faulty in one, as I contend the material is faulty in the great bulk of Light Brahmas, then it is the Light Brahmas who are "out of court," and not "Y. B. A. Z."

Light Brahmas were, I believe, the variety that first appeared in this country, but if I have understood Mr. H. Lacy correctly, he had long before kept Dark Brahmas in America, and, therefore, the Dorking parentage falls to the ground. Shall I say that I am disposed to believe that the Brahma in true characteristics of the breed cannot be improved by the Dorking for Dark birds, any more than by the White Cochin for Light?—Y. B. A. Z.

EXCESSIVE RAILWAY CHARGES.

I THINK I can throw some light on the reason why fowls are charged so much more on the return journey from shows than when going.

At Bristol Show, in January, 1867, I was charged 8s. more for my fowls returning than going. I remonstrated, and was told it was the carriage from the Show to the station. Calculated on the number of pens shown, this was £10 or £50 nett to the Great Western Railway. At Weston I am charged 5s. 3d. from the Show to the station, by the Secretary of the Show. This is £30 clear profit to some one out of the pockets of exhibitors.—BRAHMA.

WHEN at the Newport Show in December last I claimed a pen of Cerve-Cour fowls, which were forwarded per London and North-Western Railway in due course. On the arrival of the parcel I found the charges so excessive that I refused to pay them. The weight was 36 lbs., and was charged 7s. 6d. from Newport to Leeds; and from Leeds to Pudsey by Great Northern Railway 10d., the proper charge. The Great Northern Company had "paid on" the 7s. 6d., and demanded the total, 8s. 4d., from me, and the dispute still exists.

A friend of mine at Newport made the necessary inquiries for me, and sent me the reply of the London and North-Western Company, which stated the charge from Newport to Leeds for a hamper of five fowls weighing 36 lbs. to be 3s. 3d.; and I

also sent to that Company's offices at Leeds, put the same question, and have their reply, stating the charge to be 3s. 9d., so that according to their own statements I am asked double the proper rate.

I am told by the Great Northern Company's servants here that my proper course is to pay them and sue the London and North-Western Company for the difference—a course which I feel reluctant to pursue, though I am determined to make a stand in this case, it being the largest amount of four hampers which are similarly charged, and all occurring in the same month, three of them being in the hands of the Midland Company from the Birmingham Show to Leeds.

I believe from what I have seen, that most of these heavy charges are caused by the gross carelessness of the officials in neglecting to examine their scales of charges when booking parcels; and unless determination be shown by those receiving poultry by rail not to be overcharged, we shall look in vain for any reform in this respect.

For the benefit of myself and many I know to be often in the same difficulty, I should feel it a favour if you will kindly say whether it be more advisable for me to pay the whole, and sue the London and North-Western Company, or to refuse to pay till the account be corrected?—E. HUTTON, *Pudsey*.

[Were we similarly treated we should refuse to receive the birds, unless the railway officials agreed that if we did receive the birds it should be without prejudice to our resisting payment of the excessive charges. As your case stands we should refuse payment to the Great Northern, and then, if the Company sued you in the County Court and recovered (which we doubt), you might sue the London and North-Western for the overcharge. You had better consult a solicitor.]

THE HOUDAN'S FIFTH TOE.

ALL poultry fanciers should thank you for your answer to a correspondent in your issue of the 13th inst., headed "Points of Houdans."

The only points in which "improvers" suggest "improvements" in Houdans are—1, By getting rid of the fifth toe, which predisposes to lameness; 2, To obtain hardier birds. To this I answer—1, Of the many hundreds of Houdans I have had and bred, I have never had a case of lameness; 2, Houdans are very hardy and bear confinement wonderfully, and I do not believe there is any cross that could make them harder. Why, then, strive to obtain "crosses and nondescripts, the drafts and refuse of yards," when the pure stock is so good?—SANGRE AZUL.

ROUP AND CANKER IN PIGEONS.

I HAVE been much interested in the various correspondence that has lately appeared in your columns relating to Pigeons, and think much credit is due to Mr. J. Huie for his able critique on Mr. Tegetmeier's "Pigeons;" also for his remarks on the supposed contagious diseases of roup and canker.

So far as my experience goes I have never found roup to be infectious, but cannot say the same regarding canker. Last season I lost several feeders through this malady; and as my birds are kept scrupulously clean, I am inclined to attribute its origin to the fighting of some of the cocks, one of which was affected with canker. I may mention that I found a strong solution of alum very efficacious.

The fancy now stand in need of a practical work on Pigeons, as publications similar to Mr. Tegetmeier's have no weight with fanciers. I would propose that some of our leading fanciers favour us with an occasional article in your columns on the different varieties of fancy Pigeons, and thereby elicit the opinions of others. By so doing I think we are likely to obtain much useful information, and a volume so compiled would, I am sure, be most acceptable to every class of Pigeon-keeper. Perhaps the members of the Columbarian Society will favour your readers with articles on the subject, and by so doing will greatly advance the objects of the Society.—AMATEUR.

DUBLIN POULTRY SHOW.—As this is to be an Irish Session in Parliament, may I hope the same attention may be drawn to Irish Poultry Shows in your Journal, to notice the forthcoming Dublin Society's Show? The poultry department is divided into classes for Dorkings (Silver Grey and Coloured), Spanish, Game, Brahma Pootra, Cochin-China, La Fleche, Houdan,

Crève-Cœurs, and Hamburgs (Spangled and Pencilled), with prizes of £2 and £1. Turkeys, Geese, Rouen and Aylesbury Ducks have each three prizes allotted to them, varying in value from £3 to 10s. There are eight classes for single cocks. Unfortunately no efforts hitherto of exhibitors have been successful in inducing the Society to add a variety class, and also one for Bantams. The objectionable rule of requiring exhibitors to pen their birds, will, I fear, prevent distant exhibitors competing; otherwise I see no reason why this should fall behind the late excellent Shows at Limerick and Cork, where the care and attention bestowed on the birds, as well as the general good management, must be appreciated by all exhibitors, among whom is included—**EBLANA.**

CUP AND PRIZE GAME FOWLS—SORTS AND COLOURS.—No. 3.

3. **PILE OR PIED.**—*Cock*.—General colour a bright red piled on a white ground. Beak light. Comb, face, gills, and deaf-ears, bright red. Head bright red. Neck-hackle chiefly red with white streaks, but white underneath. Back bright red, a little pied with white. Shoulders and the upper wing bright red. Lower wing chiefly white. Breast well marbled with red on a white ground, as better than all white. Thighs chiefly white, a little red. Tail white with red feathers at the base. Legs, feet, claws, and nails, white or whitish; yellow legs come next, and yellowish willow legs third. The reddest and brightest red Piles are the best birds as a rule. As to the eyes of Pile Game they must invariably be bright red, as yellow and all other colours of eyes are very inferior, as are dull-coloured birds.

Hen.—General colour white thickly veined and streaked with bright red all over, the tail included. Breast also veined with bright red. The other points to match the cock.

4. **DUCKWINGS.**—*Cock*.—General colour either birchen grey, yellow birchen, or silver grey. Comb, face, gills, and deaf-ears all bright red. Eyes red for cup birds. Neck-hackle the same as the general colour, striped with black stripes underneath. Back the same as general colour, or coppery. Upper wing the same as back. Lower wing cream colour. Blackish butts. Wing with steel-blue bar. Breast dark bluish black. Tail dark greenish black. Legs, feet, and nails, willow for cup birds.

Hen.—General colour a bluish grey thickly frosted with silver all over. Neck-hackle silvery striped with black. Breast a pale or silvery fawn colour. Thighs the same. Tail of a dark greyish black. The rest to match the cock. Red fawn breasts look coarse for these hens. Birchen Greys, willow legs or olive. Yellow Birchens, yellow legs, yellow eyes. Silver Greys, white or blue legs if pure.

5. **BLACK.**—These have taken a few cups; they should have large, bold, full black eyes, and blackish beaks. Legs bluish black, very dark. *Cocks* either brassy-winged or all black. *Hens* entirely black. Red combs are preferred, but gipsy combs are as good. The blacker the legs and beaks are the better. Olive-green legs are bad. The nails should always be blackish.

6. **DARK GREY (Dark combs).**—These should be cup birds, being the very gamest sort of all, but being classed with Duckwings at exhibitions are not enough noticed by judges, and are not common, Duckwings being greater favourites, though not with the cockers. Hens should be much darker above than the cocks, though not so under the feathers. The eyes, large, bold, and full, and jet black. Black legs, feet, beaks, and nails. Dark Birchens much the same, though not so game. General colour in cocks dark silver grey or birchen grey. In Birchen cocks, dark birchen. The hens dark blackish grey, in the Greys, and as dark with birchen hackles in Birchens.

7. **WHITES** sometimes take prizes before the Piles, and should be entirely white with no yellow tinge. Bright red eyes and white legs, feet, and nails are essential. Yellow and willow legs and yellow eyes are inferior, usually being accompanied by a yellow tinge in the plumage.—**NEWMARKET.**

WAVERLEY POULTRY SHOW.

This Exhibition was held on the 19th and 20th inst., in the Corn Exchange, Melrose. It is only a year ago since it was established, and on the first occasion there were about 250 entries. Whether or not it be due to the historical associations connected with the place, or to the fancy for domesticated fowls which prevails in the district, we know not, but this year the entries were nearly doubled, there being about

450 pens. But it was not the numbers so much as the excellence and variety of the fowls which commanded the attention of visitors. We think there have been few better exhibitions in Scotland than that at Melrose, although, in other years, it would be advisable to divide the old from the young classes.

There was a splendid display of *Pigeons*, the best we have seen out of Birmingham; and the exhibition of *Canaries*, although not the best that has taken place in Scotland, was at least highly creditable to an institution of such recent origin as the Waverley Poultry Association. —(*Scotsman*.)

The following is the list of awards:—

DORKINGS.—First, J. White, Warlaby (Grey). Second, Lord Binning, Mellerstain. Third, A. Cudde, Melrose (Silver). Highly Commended, Duke of Buccleuch (Silver); D. Hardie, Sorlie, Ewes, Langholm (Dark); D. Gellatly, Meikle. Commended, D. Hardie (Silver); R. Reed, Longtown, Cumberland (Coloured); Lady G. Montgomery, Stobo Castle, Peebles (Silver).

SPANISH.—First, H. Eddon, Goitstock. Second, W. Veitch, Dingleton. Very Highly Commended, A. Redpath, Edinburgh. Highly Commended, J. H. Wilson, St. Bee's; J. Taylor.

COCHIN-CHINA.—First, Gunson & Jefferson, Whitehaven. Second, J. Elgar, Osmanthorpe Hall.

BRAMA POOTRA.—First, J. Shorthose, Newcastle-on-Tyne. Second, J. A. Dempster, Stirling. Highly Commended, G. H. Plummer, Dalkeith; J. Shorthose. Commended, Marchioness of Queensberry, Kilmount; Miss Aglionby; W. R. Park; J. Anderson, Meikle.

GAME.—First, J. H. Wilson. Second, H. M. Julian, Hull. Highly Commended, Mrs. Turnbull, Jedburgh (Black Red); W. Urquhart, Langholm; J. McGregor, Crief. Commended, Miss Aglionby; A. Robinson, Longtown.

HAMBURGH (Golden-pencilled).—First and Second, H. Eddon. Highly Commended, W. R. Park.

HAMBURGH (Golden-spangled).—First, A. Hatelie, Selkirk. Second, S. & R. Ashton, Mottram. Highly Commended, Mrs. Brown, Abercainry, Crief; S. Burn, Whithy.

HAMBURGH (Silver-pencilled).—First and Second, H. Eddon. Highly Commended, W. R. Park.

HAMBURGH (Silver-spangled).—First and Second, H. Eddon. Highly Commended, Bowman & Fearon, Whitehaven; W. R. Park.

ANY OTHER VARIETY.—First and Second, H. Eddon. Third, D. Gellatly (Padue Chamois). Highly Commended, Hon. Miss E. de Flahault (Crève-Cœur); Gunson & Jefferson; W. R. Park (Crève-Cœur). Commended, J. Elgar (Crève-Cœur).

GAME BANTAM.—First, W. Scott, Jedburgh (Black Red). Second, W. Mabon (Duckwing). Highly Commended, W. Mabon, Jedburgh (Brown Red); W. Easton, Jedburgh (Black Red); J. Hervey, Jedburgh (Brown Red); J. Wood, Chorley (Duckwing). Commended, Hon. Miss E. de Flahault (Black Red); J. Hervey (Black Red).

BANTAMS (Any other variety).—First, W. L. Graham, Melrose (Black). Second, H. Eddon. Very Highly Commended, J. Hood, Lintalce, Jedburgh (Golden Sebright); T. C. Harrison, Hull; S. & R. Ashton (Black); Lord Binning (Gold-laced); T. Watson, Crief (Golden Sebright).

BANTAM COCK.—First, Bowman & Fearon (Game). Second, W. Scott, (Black Red). Commended, R. Paterson, Melrose.

DUCKS (Aylesbury).—First, Bowman & Fearon. Second, Lady G. Montgomery. Very Highly Commended, D. Hardie. Highly Commended, D. Hardie; Lord Binning; J. A. S. E. Fair, Jedburgh; J. Scott, Newhall. Commended, G. Dryden, Selkirk.

DUCKS (Rouen).—First, Gunson & Jefferson. Second, D. Hardie. Highly Commended, D. Hardie.

DUCKS (Any other variety).—First and Second, T. C. Harrison, Hull (Carolinian and Pintail). Highly Commended, Hon. Miss E. de Flahault (White Gull); H. Eddon; S. & R. Ashton (Carolinian); S. Burn (Black East Indian). Commended, A. Thomson, Maithill (Muscovy).

SPILLING CLASS.—First, H. Eddon. Second, D. Hardie (Dorking). Third, W. R. Park (Silver-spangled Hamburgs). Highly Commended, W. R. Park (Golden-pencilled); J. A. S. E. Fair (Aylesbury Ducks). Commended, Miss Aglionby (Pile Game Bantam); T. L. Jackson (Dorkings); J. Sword, Jedburgh.

COTTAGERS' PRIZE.—First, W. Hart, Melrose (Brahma Pootra). Second, D. Waugh, Melrose (Spanish). Third, W. Miller, Selkirk. Highly Commended, L. Thompson (Golden-spangled Hamburgs).

TURKEYS.—First, Lord Binning (Cambridge). Second, Miss Porthwick, Flimby, Maryport (Cambridge). Highly Commended, T. L. Jackson; J. Elgar.

GESE.—First, Mrs. Birkett, Droom Rigg, Ainstable (Toulouse). Second, W. Paterson, Langholm (White). Highly Commended, Duke of Encleuch, Dalkeith.

PIGEONS.

PASTAILS.—First, J. Thompson, Bingley. Second, H. Yardley, Birmingham. Highly Commended, W. R. Park; R. B. Chouler; J. Hawley, Bingley, Leeds; A. Smith, Broughty Ferry; J. Grant, Corstorphine, Edinburgh. Commended J. Spence, Musselburgh.

POUTERS.—First, J. Hawley. Second, J. Grant. Highly Commended, H. Eddon; H. Yardley; J. Grant; J. Towerson, Egremont. Commended, W. Martin, Ayrton.

NCNS.—First, R. Paterson, Melrose. Second, J. Thompson. Highly Commended, R. Davidson, Swinnie, Jedburgh; H. Yardley. Commended, W. R. Park.

JACOBS.—First, H. Eddon. Second, J. Thompson. Highly Commended, Hon. Miss E. de Flahault; J. Hawley; J. Thompson; G. Yule. Commended, J. Spence.

TURBITS.—First, J. Waddell, Carnwarth. Second, J. Thompson. Highly Commended, R. Paterson, Melrose; W. R. Park; J. Towerson. Commended, R. B. Chouler.

OWLS.—First, H. Yardley. Second, J. Towerson. Highly Commended, R. Paterson; H. Eddon; J. Thompson.

TRAILERS.—First, J. Baillie, Bellevue, Aberdeen. Second, R. Whitaker, Delph Hill. Highly Commended, J. Hawley; H. Eddon; H. Yardley.

ANY OTHER VARIETY.—First and Second, J. Hawley. Highly Commended, A. Goodfellow, jun., Jedburgh (Victorian); Hon. Miss E. de Flahault (Runts); H. Eddon; J. Campbell (Marpies); J. Thompson; P. A. Renwick, Kelso (Barbs); H. Yardley; J. Baillie; J. Towerson.

SELLING CLASS.—First, J. Hawley. Second, J. Thompson. Highly Commended, J. Spence (Fantails); P. A. Renwick (Turbits); H. Yardley. Commended, J. Hawley; H. Beldon; J. Thomson.

CANARIES.

DON (Yellow or Buff).—Cocks.—First, W. Boggie, Priory. Second, J. Kemp, Galashiels. Commended, J. Dodds, Weirhill, Melrose. *Hens*.—First, W. Tiffin (Yellow). Second, W. Boggie (Buff). Commended, J. Kemp (Buff); W. Fairbairn, Joppa (Yellow).

YELLOW, BUFF, OR FLECKED.—Cocks.—First, J. Cleghorn, Galashiels (Flecked). Second, W. Balmer, Hawick (Buff Flecked). Highly Commended, J. Kemp, Galashiels (Buff Flecked). *Hens*.—First, W. Balmer (Yellow). Second, J. Kemp (Buff Flecked). Highly Commended, J. Renwick, Melrose (Yellow Flecked).

CAGE BIRDS (Canaries Excepted).—First, Miss Paterson, Melrose (Goldfinch). Second, W. Hart (Goldfinch Mule). Third, W. Balmer (Goldfinch).

The Judges were Mr. Teebay, Fulwood, Preston; and Mr. John Young, Hawick.

TUMBLER PIGEONS.

HAVING for some time past seen notices about Ground or House Tumbler Pigeons, and their modes of turning, I last summer procured a pair from the widow of the late Mr. B. P. Brent. Mrs. Brent was most anxious to send me good birds, and took much trouble to select the best she could spare at the time. The hen is not very different in appearance from an ordinary Black Tumbler Pigeon of small size. The cock bird has large, one might almost say clumsy wings, and a large, heavy head; the neck leaving the skull more in the line of the beak than in other varieties of Pigeons, and it may be that the form of the brain gives rise to this most singular power of tumbling close to the ground, for it certainly does not arise from disease. In some cases it amounts to a defect, for a Pigeon tumbling so much as the old cock does, could not live without protection. The hen seldom tumbles in the aviary; but if the cock is forced to fly, he rarely rises a foot from the ground without turning over on his back, and apparently hitting the crown of his head on the floor.

These birds breed well, but the nest is made on the ground, as they cannot or will not rise to a shelf only 18 inches above it. Two pairs of their young were allowed to fly at large, and all did well for some months, one pair being still at liberty. They all flew well, rising high in the air, and tumbling most dexterously. After a time the older pair were helplessly attacked with tumbling fits, and often lost all control over their own movements, and were therefore shut up.

Wind appears to excite all Tumblers to roll, whether Air or House kinds, and the cleverest feats are generally performed against the wind. On a breezy afternoon last autumn, I saw a House Tumbler on one of the walks at some distance from the house, and thinking it had rolled to the ground, I started it to send it home. It rose a few yards, and then rolled tail over head to the ground. It was raised a second time, and got higher, but when it felt the wind above the trees it rolled again and alighted in a maple tree. When driven off the tree it did its best to reach its home, but was again attacked by a fit of tumbling and rolled away down over the lower lands where I lost sight of it, and it was not seen till the next day, looking somewhat the worse for its adventure, but was soon well again.

I find that when these birds roll to the ground they must not be started at once, but left to themselves, when they are more likely to calm down, and then they often fly well, and like ordinary Pigeons. I therefore conclude that the rolling arises from a nervous affection, which differs very much in different birds of this breed.

I mentioned the effect of wind on these birds in causing them to tumble to such an extent as to make them so far powerless for the time; but the effect is still greater with wind and snow together. During an east wind, with a little snow, I found a young cock, a healthy strong bird, standing on the snow in an open part of the ground, where he had remained nearly all day, and in the afternoon I tried to make him fly home, but his motions were most singular and erratic, and he got still further from where he wished to fly to, and after several trials he rolled with some force into a thick holly bush, where I secured him. Since being shut up his powers of tumbling have increased, and he now makes a very complete wheel on rising only a foot from the ground, yet possesses strong powers of flight, and is unusually perfect in plumage, and very healthy.

Such an affliction as this excess of tumbling could only continue in a race of domestic birds well cared for, as one roll to the ground in sight of a cat would be the last one. Yet the Hawk does not appear to take advantage of the weakness. A

hen Sparrowhawk used to pass over the place twice daily; her approach was known by the Starlings and Pigeons rising in the air, but I have never known her strike a Pigeon, although I have often seen her pass a flock of Tumblers, and take a Sparrow beyond them. I fear a cat would not be so considerate to the Pigeons, nor would the Hawk, if she saw that the tumbling arose from disease or a defective power of wing, for she more than once did her best to strangle my poor pinioned Peeseweeps running in the garden.—A. J. A.

IMPROVED COTTAGE HIVE.

We have not used the hive, but the best answer we can give to our correspondent is to extract what Mr. S. Devan Fox states in a contemporary Journal.

"Mr. Taylor, in some of the later editions of his 'Bee-keepers'

Mannual,' gives a description of a flat wooden-topped straw hive, which I have found, after many years' trial, to be one of the simplest, and at the same time one of the most remunerative hives I have ever possessed.

"I have made some alterations in the dimensions and mode of construction, but the main features of the hive are taken from Mr. Taylor. There are three cone-shaped holes for communication with supers; they may be covered with simple blocks of wood on a plain surface, or slides made of zinc may be adopted.

"The chief advantage of the pointed aperture is, that when the slides are pushed in from the outside, the bees are gradually urged out of the way; the risk of crushing the bees being thus reduced to a minimum, as certainly not more than one bee can be injured. These three apertures are intended for communication only with one super, whether of glass, straw, or wood, although, if preferred, three can be worked at once; but this is a plan I cannot recommend when large supplies of honey are desired."

We know that it is manufactured by Mr. Lee, Windlesham, Surrey, and probably by Messrs. Neighbour, and Mr. Pettit.

STRANGE PHENOMENON IN THE BEE.

THE bee, though generally supposed to be almost dormant in winter, has the peculiarity of sounding at twelve o'clock at night on the 6th of January. A single bee appears to give the signal, sometimes one, sometimes two, and I have even heard three distinct sounds as signals; then a sort of melancholy harmonious sound is emitted by the whole hive, and continued for a minute or two, however frosty the night may be. This year I had eight hives watched, in two gardens two each, and four in another; the gardens about 200 yards from each other. The first hive sounded at seven minutes to twelve o'clock, and the last at twelve o'clock by gun time, all the eight hives having sounded in the interval. How the little insect marks that minute of time once a year is certainly a poser for the scientific class.—GEORGE WILSON, *Whalton*.

[It is essential to the very existence of bees that the temperature of the cluster shall not fall below a given point, and as they are only able to evolve heat by increased activity of their respiratory organs, it follows that whenever the interior of their dwelling becomes too cold for them, quickened breathing, producing a "melancholy harmonious sound," is the necessary consequence. This is, perhaps, more likely to occur about twelve o'clock during a January night than at any other time, and is probably the true explanation of the supposed phenomenon.]

PRICE OF LIGURIAN BEES, AND OF FRAME HIVES.

So many applications reach me, both in my own name and under the *non de plume* of "A DEVONSHIRE BEE-KEEPER," with regard to the prices of Ligurian bees, and the cost of frame hives, that I am induced to state that my price for healthy stocks, including frame hive of the best description, is four guineas, or persons sending their own "Woodbury" hives may have them furnished with bees, combs, and frames, for £3 5s. Swarms during May and June, two guineas and a half, after

that time two guineas, exclusive of hives. I have also made arrangements for importing queens from the best locality in the Italian Alps, which will enable me to supply them throughout the season at one guinea, and in the autumn (October), at half a guinea each. Frame hives, either in straw or wood (the former recommended), one guinea.

In all cases the purity of queens, and the safe transit of queens and bees to any part of Great Britain and Ireland, are guaranteed.—T. W. WOONBURY, *Mount Radford, Exeter.*

ARTIFICIAL SWARMING IN COMMON HIVES.

As many of your readers still keep bees in the old-fashioned straw hives, or in hives without bars, it may interest them to know that artificial swarms can be made from them without difficulty, and quite as profitably and successfully as out of the most approved bar-and-frame hives. All that it is requisite to know is how to drive bees efficiently. The mode of operating must first be mastered according to the instructions so lucidly given by "A DEVONSHIRE BEE-KEEPER" in recent numbers of "our Journal." To any one familiar with the art of driving, the further process is easy, and can rarely fail of success; in fact, I have never yet known an instance of failure with ordinary care.

My plan is to make one swarm out of two hives; and it is carried out as follows:—Let A and B represent two strong hives (strong in numbers they must be), standing side by side or far apart, it matters not which, although success will, perhaps, be the surer as they are more remote from one another. I generally prefer to make these swarms somewhat early in the year, so as to anticipate the natural issue of swarms, but not earlier than the first week in May, and later, of course, in backward seasons. Begin by driving A into an empty hive. As soon as the queen is secured with a tolerably large swarm of bees, put the driven bees on the stand lately occupied by A. Remove A to some distance, say 20 yards or so, allowing the bees to come out of it if they please. They will naturally find their way to their old stance, and remain with their queen and companions in the new hive. The next day remove B to a new stand in the busiest part of the day, and put A on the stance vacated by B. The last-mentioned hive should be permanently located at some distance; in fact, it will be advisable to have your apiary divided into two, with as much space intervening as you can conveniently allow, so as to lessen the chance of too many bees returning to their old hive. The work is now done. It only remains to see that the swarm is not starved in bad weather, which, by the way, often destroys many natural swarms, when the bees are unable to go out foraging.

The principle of this method of making artificial swarms is not original. It is that which Langstroth, the eminent American bee-master, published to the world years ago. Its merit lies in its great simplicity, which it has in common with many greater inventions.

By this plan we have the greatest chance of success with the minimum of risk. First, natural swarming is anticipated, and the grievous disappointment occasioned by the flight and escape of swarms is avoided; secondly, all excessive swarming is put a stop to; and lastly, there is the greater hope of an abundant honey harvest, for the swarm being early and strong (as it always must be by this plan), it has the whole season before it. If honey abounds, supers will soon have to be given. If, on the contrary, the season is an indifferent one, these early and strong swarms will have so much the better chance of surviving.

At the same time some attention must be paid to A and B. As the former will have to rear a new queen, there will be some chance of its sending out a swarm in the course of three weeks or so; but this will rarely happen except where a very large quantity of brood was left by the old queen when the first swarm was made. In this case the former process may be repeated, by driving a swarm out of B, locating it on B's stance, and the following day, when the population of B has been thinned, putting B in place of A, and moving A to a new stand.—B. & W.

SILKWORM-REARING IN ENGLAND.—No. 6.

The preparation and construction of materials for silkworms to spin in require the attention of every silkworm-rearer some time before the worms commence work. The method of

twisting papers thimble-form, practised in England, is all very well for the amateur with a few score worms, but would not do where hundreds of thousands have to be provided for; a more simple and expeditious way is then requisite. I shall describe three or four of the best systems, and one of recent invention by Count Delprino.

The broom system is that most commonly adopted; it is an ancient method, and answers very well when properly carried out. It consists in preparing small brooms, formed of branches and stems of various trees or plants without thorns. Half a dozen or more such stems are tied together within an inch of their bottoms, leaving the top expanded and open, or full of spaces an inch or more across. The diameter of the top or open part is about 4 inches, and that of the bottom where tied little over an inch. They can be tied with garden matting, twigs of the willow, or thin iron wire previously made pliable by being heated red hot. They must be made 6 inches higher than the distance from stage to stage, or about 2 feet, their tops being easily bent; for when stood on a stage they should be made to curve beneath the stage above them, by which means they are secured in position. At 6 inches apart about eighty, set in single rows, will fill such a stage as I have described, but if in double rows, each alternate broom being curved in opposite directions, and placed on the cross pieces at 4 inches apart, about one-third more will be required. The double row is, perhaps, to be preferred, as the worms are better distributed, having extra room to work in. On finding the foot of a broom they crawl up into the open head, and mostly to the very top, directly under the stage above, and there begin to work. The materials for forming these brooms should be thoroughly dry before use. I have found the most suitable to be the common broom found in woods and about commons, garden cress which has run to seed, twigs of oak with the leaves, or of elm, dardish and turnip tops, the stems of various woody weeds, garden flower stalks, and mixed therewith, pea straw in which the insects readily spin. Nothing of a thorny or prickly nature, or with a disagreeable odour, should be used. Into the head or centre of the brooms it is an excellent practice to place a small handful of shavings, straw, pea haulm, &c.

The above is the most simple and generally adopted system, but I find it defective, inasmuch as many worms pass between the brooms, unable to find and mount them, and thus suffer; often so losing time, wasting their silk over the leaves, and eventually spinning a cocoon with little substance. To remedy this evil my plan is to fix edge upwards across the stages laths on which to stand the brooms, making these steady by opening their bottoms to admit the laths. The silkworms go by the laths to the brooms without loss of time. The laths should be made secure in grooves formed in the inside of the side rails of the stages, and carried to within a quarter of an inch of the paper thereon. By this means they will be supported just above it, and the paper can be removed along with the dirt and excrements without disturbing the brooms.

Another system, more expeditious than making brooms, is to lay the materials across the stages, in rows about 8 inches wide at their base, and 18 inches apart, carrying them up to within 4 inches of the stage above. Then pieces of branches or sticks are laid from top to top of the rows quite up to the stage, thus making the whole steady, and forming as it were so many bridges, sufficiently high not to be disturbed or touched when feeding the worms or performing other necessary work. This method is excellent, for the worms arrive quickly at their spinning quarters, and may please themselves about remaining at the bottom or going to the top. I have found many sluggish worms which spin sometimes even among the leaves on the stages, and I particularly noticed it with the Japanese breeds, so that this system is especially adapted for them.

An excellent method also would be arranging the materials on the under part of every stage except the bottom one, and securing them by means of twine run over and laced to the cross bars before putting the silkworms' castle, or house, together—viz., to lay the stages bottom upwards on the ground; to throw over all a sprinkling of shavings or pea straw, or lath, then stems of broom, and flower stems, and over all a few oak or elm shoots, and to fix all together by lacing the twine to the ears. The materials may be about 6 inches thick in the centre, gradually diminishing to almost nothing at the sides of the stages. When the time arrives for the worms to spin, it is only necessary instead of brooms, &c., to stand up twigs or stems of plants for the worms to crawl up by to the materials already prepared. These twigs can be slit at the bottom and placed over laths as for the brooms. As the chief preparation is made

at the time the castle is put together, consequently in spring before stems of any kind are sufficiently grown, they must be procured and well dried during the previous summer or autumn.

As this method involves a difficulty with the top stage of the castle, 18 or 20 inches above which is the ceiling of the rearing room, there must be some preparation there to secure the materials, which is not the case in the broom system, for by that the brooms find support from the ceiling itself. The best way would be, when putting the castle together, to nail a 12-foot spline on each side to the tops of the supporting posts, on the inside of these, and 5 inches from the ceiling. Across the splines lay sticks, branches, or laths, and on these the spinning materials right up to the ceiling.

I must notice the invention of Count Delprino, member of the Chamber of Commerce and Arts of Alessandria, who seems to have introduced a novel and advantageous method of preparing the spinning materials, and which was to be seen in use at the late Universal Exhibition at Paris, where it appears to have attracted much attention. It is called the cell system, because each worm works by itself in a cell, with only just sufficient space to complete the cocoon. As I have not seen it in operation, I can only judge of the arrangement by having read an ingenious work of the Count's on the subject; but although my idea of it may differ from the reality, still the system is the same. It simply consists in thin boarding being fixed, on each side of which little cells are formed all over, from 1 to 1½ inch square, by gluing laths across, and filling up with thin pieces between. These prepared boards are set up instead of brooms, others being fixed to the under part of the stages. Doubtless, it requires some time to prepare such a series of cells, but the advantages are shown to be various. Each worm having only just sufficient room for itself, the production of double cocoons, the work of two or more worms, is to a great extent prevented. Less silk is wasted in outside work to attach the cocoon in a firm position, greater cleanliness is insured, with, in the end, a saving of expense. The worms lose less time in mounting and fixing on the place where they can spin, whereas in the old broom system they often fall, and either perish or produce defective cocoons.

This contrivance is easily managed, and put in position by one person. It is cleanly in use, expeditious, and will last many years. It effects a saving of from 10 to 25 per cent. of silk, economises work 6 per cent., and is productive of more uniform cocoons. It can be put up in any room without causing dirt or even dust, thus facilitating the rearing of silkworms even by ladies, of whom not a few would dedicate themselves to this amusing and profitable occupation. To facilitate ventilation the cells should have holes not larger than peas through the boards, which are not required to be thicker than a quarter of an inch. Very large silkworms require cells at least 1½ inch square, while cells 1 inch square will suffice for the small Japanese breed. I confine myself to these few observations, until I shall have myself proved the system practically.—LEONARD HARMAN, JUN.

BIRDS IN AUSTRALIA.—The stock of birds belonging to Mr. L. Underdown, at the Hindmarsh Hotel (Adelaide), is well worthy of a visit, and forms both a novel and interesting sight. The most prominent are two long cages containing about 35,000 pairs of beautiful Shell Parrots, most of them this year's birds. The noise and activity amongst them are sometimes wonderful. There are also no less than 1000 pairs of the well-known Cockatoo Parrots, besides small numbers of White Cockatoos, Magpies, and the much-admired Port Lincoln Parrot. A beautiful and delicately-marked little bird, of which Mr. Underdown has about 7000 pairs, is the Zebra Finch, so called from the striped coloured feathers appearing on the breast. We are informed that already the proprietor has sold 9000 birds of various kinds for exportation, most of them being purchased by captains of vessels going to England, to whom no doubt the establishment will prove a great convenience, while probably, with care and management, it may be made exceedingly profitable to the enterprising bird-dealer. The total number of birds in the yard would be not far short of 50,000 pairs.—(South Australian Register.)

OUR LETTER BOX.

SILVER-SPANGLED HAMBOURGS (W. Chynell).—You have not been treated liberally; but we cannot interfere. We have repeatedly warned our readers not to pay for fowls until they have seen them. A post-office order payable ten days after date enables this to be done.

GROUND OATS.—"Mrs. L. P." wishes to know of any place besides Sussex where she can obtain these for her poultry.

FOWLS WITH ULCERATED LIVERS (J. T.).—If all your fowls are similarly affected, young and old, the disease must, we suppose, be constitutional, and we should advise change of blood. Many of these diseases are hereditary. Supply the fowls freely with green food, and if you can, let them have ground oats instead of barley meal. Our cure, would, however, be fresh blood.

MANAGEMENT OF GEESSE (T. M. L.).—Almost all points in Goose management are disputed. To your first question we say, shut them all up together; second, the most successful Goose-rearer we know always leaves the eggs in the nest. We always leave one or two and take the others. These answers are in accordance with the ideas of the old women who rear Geese in the neighbourhood of large commons.

DORKING'S HEAD AND COME TURNING BLACK (Idem).—Purge the hen freely with castor oil. It is the only remedy you can adopt. Such cases often occur from poultry drinking snow water for a time.

FOWLS NOT LAYING (Kate).—You cannot eat your cake and have it. You cannot have the chickens for dinner in September and October, and for layers in December and January. Last year you had more pullets and more eggs, and that was as might be expected. It is not the property of any breed to lay in the winter; it belongs only to pullets. Directly they have passed into the mature state of hens they give up such childish habits, and lay only in the natural season. Nature has made their laying time to come on at that period most favourable for rearing the chickens. Thus, a hen just beginning to lay will be broody in or about April, will hatch out her chickens towards glorious May, when there are long days and short nights, genial air, and lots of insects. The lusty little things grow freely, and are very different from the winter chicks. This is why the hens do not lay. Your yard is badly made up for early eggs. You have thirteen bees and three pullets—"all this sack to a halfpenny-worth of bread." The laying element is sadly in the minority. Reverse your arrangements next year, and you will not complain. Have a very little patience now, and all will be well, though rather late.

DORKING'S EGGS (H. C. J.).—The colour of a Dorking's egg has no more to do with the plumage of the bird it produces than that of a man's hair has with his height.

HACKLE OF CINNAMON COCHIN-CHINA HEN (North Devon Subscriber).—There was formerly a description of Cinnamon Cochin hen, which was required to have a dark rim at the bottom of a hackle. We have seen none of them for years. We know no Cochin hen or pullet at the present day to which it is not a disadvantage, but it is not a disqualification.

SPANISH COCK'S COMB FALLING OVER AND TURNING PURPLE (Black Spanish).—We could answer with more certainty if we knew the age of the Spanish cock. If he is young and his comb is still growing, there is little hope of improvement; if he is an adult, and the comb has only lately gone over, it may be only a question of condition. Bathing with vinegar and cold water, and nourishing diet, will probably bring it up. High bred Spanish fowls are constantly playing pranks in moulting, and throwing white feathers; sometimes in two moultings, they will turn from black to entirely white, they will then become black again, but will always breed black chickens.

DISTINGUISHING THE SEX IN EGGS (Idem).—There is no plan for distinguishing the sex in eggs. An old theory was that the cocks came from pointed eggs, and the pullets from round ones. We do not believe in it. We have tried one plan, and it answered. We were told the early eggs of a sitting give nearly all cocks, and the late ones pullets. So far as we have tried it we are bound to say we find there is truth in it.

BRAHMA POOTRAS (G. W.).—We never knew the time when Light Brahmas were required to be vulture-hooked. All the books give the points of the breed, and that appendage is not among them. The production of a Brahma from the cross you name is an accident. The produce took after the father. To prove anything the same result should always follow. We were struck, as you were, by the continuous laying. Our correspondent "J. P." will no doubt give full explanations to his brother amateurs.

SPACE PIGEONS REQUIRE—FLOOR (Captain).—If your birds fly at large or into an aviary, you may keep twenty-five pairs of Nuns and Trumpeters in a space 11 feet long, 6 feet wide, and 7 feet high, having plenty of room for their breeding. If constantly confined in the space named, eight pairs will require the room so as to be kept in good plumage. A wooden floor is preferable for Pigeons. If raised off the ground only 6 or 8 inches, and if cleaned every morning as it ought to be, it will always keep dry.

PIGEON HEN NOT LAYING—FOOD (Idem).—If the Carrier hen was bred last season she will not likely lay for a month or six weeks yet. Young hens do not sometimes lay before the end of April or during May. Feed your birds well twice a day; give Indian corn, tares, and a few tick beans, and keep a constant supply of old bruised mortar and fresh water. The strongest birds never fare better. Clary is an herb related to sage. Give your Pigeons plenty of clean water to wash in, daily if possible, and a little salt mixed with fresh earth from a garden or field for them to peck at. Let the birds have the food we have named. Give no wheat except during the breeding season, and no barley at any time, as they both cause purging during winter. The harder the food at this season the better. Read our reply to "H. W." in the Journal of the 23rd ult.

PIGEON LAYING IMPERFECT EGGS (A Young Fancier).—The probable cause is that she is too "well fed." Less food and more exercise would restore her to health.

PIGEON DISEASED (Amateur).—We fear your bird will die, as the canker is so very bad. Try to remove the diseased piece with a little smooth thin bit of wood, and then rub the part with caustic, doing this thoroughly but carefully.

BEES FLOWERS (Wasp).—Sow borage, mignonette, and Nepeta Mussinii. Be assured, however, that fields of clover, sainfoin, and buckwheat, heaths, lime trees, &c., are the best sources of honey. (A. T.).—To the above answer we can merely add that there is no single flower known that does not yield honey; and the bees' harvest depends upon the country within a radius of five miles round their hive. Flowers near the apiary contribute slightly to their store, but on the country at large depends their chief store of honey. The seed of *Phacelia tanacetifolia* is in the seed lists of some of the chief London seedsmen, and therefore can be readily obtained.

From observations taken near London during the last forty-one years, the average day temperature of the week is 49.2°; and its night temperature 31.5°. The greatest heat was 67°, on the 10th, 1826; and the lowest cold 7°, on the 10th, 1847. The greatest fall of rain was 0.69 inch.

FURTHER NOTES ON LILIUMS AND THEIR CULTURE.

HAVING in my first paper confined myself entirely to the speciosum tribe, I now proceed to notice some of the less-known species. I have also ventured to make a few remarks on the cultivation of Lilies. I have had many failures, but I still work on, hoping and longing for the time when the darkness of failure shall belong to the past, and be fully recompensed by the mid-day splendour of complete success.

Ree Hakoe (Groenewegen).—Petals broad and overlapped at the base. Flower large, and nicely recurved; form almost perfect; peculiar salmon-coloured ground, bright yellow band in the centre, tips of the petals bronze red, a few maroon spots, and here and there a crimson stain. Erect-flowering, about 12 inches high. Very distinct, peculiar, and fine. Quite of the eastern style of colour.

Buschianum (Van Houtte).—Small flower, neatly recurved, and of perfect shape; vermillion wax-like ground, with a few small dark spots. Erect-flowering, about 30 inches high. Scent rather unpleasant. The stigma is shorter than the anthers. Very perfect and beautiful.

Concolor (?) (Hooper & Co.).—Petals broad, and just meeting at the base, beautifully recurved; centre of the petals yellow, tips bright crimson blood colour, dark spots. Erect-flowering, about 30 inches high. Slight scent. Stigma and pollen very dark. Very brilliant; almost perfect in form and colour. I have recently heard from a first-rate authority that "the flower of the true *Concolor* is somewhat star-like, the petals very little recurved, and of a singular red—vermillion with a coppery hue; occasionally, but very seldom, a few dark spots."

Formosum (A. Verschaffelt).—After the style of *Ree Hakoe*, but much better. Height about 2 feet. Very beautiful.

Fou Kwam (Barnaart).—Very large and fine; style of *Ree Hakoe*, but larger, not so much recurved, and very few spots.

Ja-Ehal (Barnaart).—Same style as *Ree Hakoe*, but not quite so large, more recurved, and rather darker. *Ja-Ehal* from Groenewegen was very different from this, being much like *Thunbergianum citrinum*. I do not know which is the true *Ja-Ehal*.

Sygets (Groenewegen).—Petals narrow, and each one separate from the other. Flowers large, well reflexed, and of good form; citron ground, with yellow centre, a few purple maroon spots; bright maroon tip to stigma. Erect-flowering, about 12 inches high. Novel and pretty.

Ideno Sato, Ogontio, Kemigajo, and Ki-kak, had from Groenewegen; *Thunbergianum aureum nigro-maculatum*, from Van Houtte; and *Thunbergianum citrinum*, from Barnaart, are all similar in style to *Sygets*.

Browni, or *japonicum verum*.—Very large trumpet-shaped flower; pure white inside, outside stained with dull purple. Very beautiful and distinct. I find it will occasionally lie dormant for a season.

Longiflorum, *eximium*, *Takesima*, and *Liu Kiu*, all have very beautiful trumpet-shaped white flowers, and are worthy of a place in every collection.

Wallichianum has immense, somewhat trumpet-shaped flowers of pure white colour, and is very beautiful, but I find great difficulty in inducing it to bloom; with me it is continually splitting up into small offsets. I suppose I have not as yet found out the proper way of cultivating it. I hope for instructions from some of the contributors to "our Journal."

When I began to grow Lilies I used nothing but sandy loam, but I did not find it very satisfactory, as the soil soon became sour, and I consequently lost some of my best Auratums. I next used nothing but fibrous peat, with plenty of coarse sand, and a good quantity of crushed charcoal, also a small quantity of cocoa-nut refuse. This was a great improvement on the old soil, and the Lilies did well; but I find an addition of 25 per cent. of good turfy loam is better still, as it gives more for the plants to feed on. Plenty of drainage must be given, otherwise the buds will drop, even if the Lilies do not die.

At first I always put silver sand round the roots when I potted my Lilies, but I cannot recommend the practice; the bulbs appear to prefer immediate contact with the soil.

Many of the Lilies, if in perfect health, emit rootlets from the stems just above the surface of the soil; these rootlets should receive every encouragement, and I believe the general course adopted is to shift into a larger pot. This plan I do not like, as Lilies are often over-potted, which is a great evil, not to mention the additional space required at all seasons. I have had some zinc collars made from 1½ to 2½ inches wide, and of lengths to suit the various sizes of pots. These collars are cut one out of the other, and are, therefore, inexpensive. One end, for 1½ inch of its length, is about a quarter of an inch wider than the rest, and this extra width is turned over so as to form a sheath for the other end when the collar is bent for use. When the rootlets appear I put one of these collars round the inside of the pot, and fill up with proper soil. In the autumn the collars and additional soil are removed.

Lilies require great attention during the earlier stages of their growth, otherwise they will become drawn and unsightly. Until they are growing vigorously water should be used but sparingly, but afterwards they require a plentiful supply.

About the middle of May I turn my Lilies out of the greenhouse, and place them on coal ashes in a sheltered part of the garden, and to prevent danger from frost and heavy rains I place a temporary covering of tiffany over them. I bring a few pots at a time into the greenhouse, and so obtain a long succession of blooms.

Shortly after the Lilies have done flowering I lay the pots on their sides to prevent excess of moisture, which is very injurious to Lilies in the autumn. When they have matured their growth I place them under the stage of my greenhouse, where all the attention they require during the winter is a slight syringing occasionally to prevent the soil from becoming dust dry. In January and February

the supply of moisture should be slightly increased, and immediately there is any appearance of growth the pot must be brought up to the light. I have shelving boards put beneath the stages to prevent the drip from the other plants reaching the Lilies. Drip is death.

Most persons advocate repotting in the autumn, but I prefer doing it in the spring. When shifted in the autumn there is no root action going on for months, and there is great danger of the bulb suffering either from the soil being too dry or too wet; but if potted in January or February, the roots lay hold of the soil at once, and grow vigorously. Last March I had some choice Lilies from Prussia; they were shaken out of the pots, and sent to me packed in damp moss. I potted them carefully, and although some of them had made considerable growth when received, none of them suffered from the late removal; in fact, they were some of my healthiest and best plants.

I have said nothing about keeping the plants clean and free from blight, and properly tied. Lovers of the beauty of the Lily cannot be tolerators of filth and deformity.

I am neither an artist nor a botanist, and, therefore, fear that my attempts to describe the various Lilies noticed, will not convey a correct idea of their forms and colours, but I ask pardon for all my errors and shortcomings.—*Hesperus*.

ESTIMATE OF SOME VARIETIES OF POTATO.

BEFORE stating the result of my trial of fourteen sorts of Potatoes, I must describe the garden and soil. The garden is about half an acre in extent, or a little larger, surrounded with buildings and walls, yet well exposed to the sun; medium garden soil, rather poor. It grew a good crop of Potatoes the season before, and received no fresh manure for the trial crop. All the sorts were somewhat injured by the late frost in May, but being all near together were injured alike. The sorts were

- | | |
|--|-------------------------------|
| 1. Albion Ashleaf Kidney. | 8. Cheshire Pink Eye. |
| 2. Rivers's Royal Ashleaf Kidney. | 9. Prince of Wales Kidney. |
| 3. Ashleaf Kidney (old variety), a very fine true stock. | 10. Somerset Reds. |
| 4. Mona's Pride Kidney. | 11. Ash-top Fluke (Carter's). |
| 5. Myatt's Prolific Ashleaf Kidney. | 12. Fortyfold. |
| 6. Milky White (Wheeler's). | 13. Paterson's Victoria. |
| 7. Early Oxford. | 14. Fluke. |

Of each of the above fourteen sorts I selected four good, medium-sized tubers, taking great care of them. This is a point much neglected by Potato-growers. From my experience and observation, I fully believe that if growers would pay more attention to the seed they plant, they would obtain far larger crops than they do. I have at this moment received a sample of four tubers from a person who has bought a ship-load from France or Ireland, with a message that they are only fit for planting; but on examination I should say they are very unfit, being so terribly bruised. Parties are buying these at 12s. per sack, because they are cheap, without a thought of the crop in future. However, say what one will, some people will throw away a pound to save a shilling. To proceed, then—

1. *Albion Ashleaf*.—The four tubers yielded 2 lbs. 2 ozs. of produce of good flavour and quality. The yield of this sort where not touched by the frost was much larger. It is a first-class kind, being good in quality and very prolific.

2. *Rivers's Royal Ashleaf*.—Yield only 1 lb. of small roots, quality only moderate. Somehow this sort varies very much; on some soils it is almost worthless, takes the disease, is a poor cropper, and almost flavourless; while on other soils it is quite different, being good in crop and quality.

3. *Ashleaf* (old variety).—Yield 2 lbs., very good in quality, but not so dry as or equal to Albion.

4. *Mona's Pride*.—Yield 3 lbs., not quite so early as No. 1, but a first-class prolific Potato, and a sort that seems to suit all soils alike.

5. *Myatt's Prolific Ashleaf*.—Yield 2½ lbs., but badly diseased. A well-known second early Kidney, which certainly does better on some soils than others. On mine it is of very poor quality.

6. *Milky White*.—Yield 1 lb. 5 ozs., of first-class quality and appearance. It was very weak in growth, and in consequence, I believe, the frost had more effect upon it, hence the light weight; and while we ought, I think, to grow the strong kinds, yet this is a favourite with me, and I mean to continue growing it, as the yield of other plants not injured by the frost was very good.

7. *Early Oxford*.—Yield 2½ lbs.; quality only second-rate. This being yellow, and preferring a white Potato, I have discarded it; yet to those who do not object to a yellow Potato, it is a passable sort.

8. *Cheshire Pink Eye*.—Yield 1½ lb. First-class in point of quality and whiteness, but weak in growth, and variable in crop on different soils.

9. *Prince of Wales Kidney*.—Yield 5 lbs. This possesses one good quality and two bad; its good quality being, that it is a very heavy cropper. It is certainly the heaviest cropping Kidney I ever knew, but this will not compensate for its two bad qualities—namely, that it is one of the kinds most liable to the disease, which spreads most rapidly; and, secondly, it is worthless in point of quality. Presuming this is its true character in the eastern counties as well as in the western, I am not surprised that we see no advertisements of the raiser this season.

10. *Somerset Reds*.—Yield 7 lbs. Extremely white, and equal in flavour and every other good quality to the Early Fortyfold, but a much heavier cropper. It is a strong grower and resists the disease; a truly first-class second early sort.

11. *Ash-top Fluke*.—Yield 3½ lbs. I wish Messrs. Carter had sent a "new thing," better worth the high charge than this. In quality I do not consider it anything like equal to either of its reported parents, and a much weaker grower than the Fluke. If we are to have a second-early Potato, let the Early Fortyfold be a standard of quality.

12. *Early Fortyfold*.—Yield 3 lbs. A well-known first-class sort, if true, needing no comment here.

13. *Paterson's Seedling Victoria*.—Yield 9 lbs. Having given such a full report of this sort recently (page 135), nothing more need be said, excepting that I have sent the Editors a sample to try and report upon.

14. *Fluke*.—Yield 3½ lbs. Very good in quality, but stringy at the tail end, and a poor cropper unless it has a change of soil every year.—*D., of Somerset, Dorset, and Wilts.*

PLEROMA ELEGANS AND STATICE HOLFORDI CULTURE.

ALL who love gardening have their own favourite flowers which are more carefully watched and tended than the general collection. The best positions in the greenhouse are assigned to them; they are more carefully handled in the potting shed; and on busy days, if the others are indiscriminately watered, more care is bestowed on the favourites. But some sorts of flowers are general favourites, and the two I wish to make a few remarks on are of the number.

The first, *Pleroma elegans*, is admired for its noble appearance as a greenhouse plant, its glossy green leaves, and its large, circular, purple flowers. The other, *Statice Holfordi*, is distinguished for its handsome branched spikes of bright blue flowers, and the length of time it continues in flower. They are generally considered greenhouse plants, but both of them are benefited at certain times of the year by a higher temperature than is generally kept up in a greenhouse; I will, therefore, describe the system of cultivation by which I grow them successfully.

PLEROMA ELEGANS is increased by cuttings of the half-ripened wood in August; and a good way to manage this, as well as numbers of other greenhouse plants, such as Azaleas, Pimeleas, Lachenaultias, and others, is to place a 5-inch pot within a larger pot, filling the intervening space with sand. After carefully placing the drainage in the 5-inch pot which is to contain the cuttings, spread over the drainage a little moss or fibre of some sort, to prevent the soil from mixing with the drainage; then fill the pot three parts full with the following compost—viz., two parts turfy peat chopped fine, one part loam, and one part silver sand, with a layer of silver sand on the top. After pressing the whole down rather firmly insert the cuttings; then place the pots on a shelf near the glass, but shaded from the sun, and water them until the water runs through the hole in the bottom of the pot. Do not give the water in the potting shed and then carry the pots into the greenhouse, as the cuttings, being inserted in sand, will be loosened and thereby injured. It is also necessary to place a bell-glass over the cuttings; the rim of the bell-glass will rest on the sand which is contained in the space between the two pots. This system of propagating greenhouse plants is the best for those who only require a limited number. The bell-glasses will require to be taken off daily, wiped dry with a cloth, and replaced almost immediately,

first removing any mould or decayed leaves, and watering the cuttings if they require water.

As soon as the cuttings are rooted they ought to be shifted into large 60 or small 48-sized pots, and in February the young plants ought to be placed in a growing temperature of from 50° to 55°. An intermediate house is the best for them. Not having the convenience of an intermediate plant house, I generally place such subjects in a vinery started on the 1st of February; they delight in such circumstances to be syringed with tepid water daily. In order to keep the plants bushy, and ultimately to make them handsome specimens, they ought to be staked out, and have the points of the young growing shoots pinched out. In June the plants will require to be shifted into larger pots. In July they may be placed in the greenhouse, and should be kept there throughout the winter. In February place the plants again in a temperature of from 50° to 55°, increasing the temperature, of course, as the season advances. As soon as the first flowers begin to expand remove the plants to the greenhouse.

I treat the *Pteroma* from year to year in the manner described, and under this treatment it blooms profusely. I generally repot, if the plants require repotting, as soon as the flowering season is past. The compost I use consists of two parts turfy peat and one part loam, with a little sand and charcoal to keep the whole sweet and porous.

STATICE HOLFORDI is another distinct and valuable plant for the decoration of the greenhouse during the summer and autumn. One excellent quality which it possesses is, that the flowers continue two or three months in perfection. It is also of a very free habit of growth, and must not be stinted for pot room. It is propagated by cuttings, which may be readily struck in a little bottom heat. I generally place one cutting in the centre of a 60-sized pot, using the same compost as that recommended for the *Pteroma*. The cuttings must receive every attention, shading them from the sun, and keeping the leaves moist. They will soon root, and will require to be shifted into pots a size larger, so that they may receive no check to their growth. Scarcely any plant will become a fine healthy specimen if it be stinted for water, or have not sufficient pot room; and this rule is especially true of *Statice Holfordi*.

I use the same compost for this plant as for the *Pteroma*, with the exception of a little rotted cow manure and a few crushed bones. The *Statice* is also benefited by being watered with weak manure water occasionally when the pots are full of roots.

The preceding remarks may be useful to those who have had any difficulty in growing the plants referred to. *Pteroma elegans* assumes a sickly appearance if it is continually kept in the greenhouse, and the *Statice* will damp-off in pieces, and the plants be rendered unsightly, but treated as above they will not fail to give satisfaction.—J. DOUGLAS.

GESNERAS FOR WINTER BLOOMING.

In reference to *Gesnera cinnabarina*, I most confidently endorse all "J. W." says respecting it. There are also several other most desirable kinds; we grow one we call *Gesnera ignea*, which is far better than *G. cinnabarina*, having finer foliage, and the flowers are extremely beautiful and bright in point of colour. For contrasting with such plants as *Cecylogyne cristata*, *Dendrobium nobile*, *D. Pierardi*, and *Eucharis amazonica*, it is remarkably fine, and as a single plant it is very striking. We have at times filled large dishes with from eight to ten pots plunged in cocoa-nut-fibre refuse; such masses are very effective.

We also grow another winter-blooming *Gesnera*, called *refulgens*, and by some *resplendens*. This is very distinct from *cinnabarina*, growing very much larger in the same time, and with the same treatment as *ignea*. We have now plants of it from 3 to 4 feet high, which have been gorgeous objects; the leaves are about a foot in diameter when well grown, and in the earliest stages of their development they are really lovely. Their colour is very distinct from that of the foliage of *Gesnera cinnabarina* and *ignea*, being mostly of an exceedingly rich maroon. For foliage alone these plants are well worth their room. The flowers are also very fine, large, and numerous, in colour a deep rose. We bring the *Gesnera refulgens* into bloom in the middle of October, and the plants continue good for three months. We then remove them to make room for the *cinnabarina* or *ignea* section. When in a small state these plants are most handsome and effective for table decoration.

There is another *Gesnera* which should be generally grown,

the name is *G. Hibbertii*; this makes a very charming contrast to the other two. In point of foliage alone, the three *Gesneras* named, if judiciously mixed, would make a very pretty picture without a flower. *Hibbertii* will endure more cold than any of the family, and we find it very useful for our conservatory during September, October, and November. It grows about a foot in height; the leaves are nearly circular, shaded with different tints of green, and, having the velvety appearance peculiar to many of this family, render the plant very desirable. The flowers are produced in great profusion; they are orange scarlet, and very effective.—WILLIAM PAYNE, *Fir Vale, Sheffield*.

LICHENS ON FOREST TREES.

I AM anxious to know, through the pages of THE JOURNAL OF HORTICULTURE, if any of your readers have observed the Lichen, so common to forest trees, on the increase of late.

Here it is increasing every year so much, that fine healthy young Oak trees are fast dying. It has also attacked the Beech, common Spruce, and Silver Fir, but not to the same extent as the Oak and Whitehorn, on which it is causing wholesale destruction. My attention being called to it about two years ago, I suggested open drains, as I thought it might have arisen from moisture at the roots, for at the place where it was then so bad the soil was a stiff retentive clay. Although these drains have now been open upwards of two years the Lichen has not in the least decreased, and now I find it has been spreading very extensively within the last twelve months. This day I had some drains, which have been made more than seven years, opened, thinking that they might be choked by roots or some other cause, and that the water was consequently prevented from flowing off by them; but I found them working most satisfactorily. They are stone drains from 2½ to 3 feet deep, with from 18 inches to 2 feet of stones.

On looking at the trees here which are so very much infested with Lichen, one would be inclined to think that the cause is damp or water about the roots; but now, seeing that drainage has done no good, and the trees are fast dying, the evil is really alarming. To use lime, &c., or any of the remedies for moss on trees, would involve endless labour and expense. I feel anxious to know if any of the readers of the Journal have observed Lichens so much in other places as we have to complain of here.

I enclose pieces (each separately named), of the young shoots of several sorts of trees severely attacked for your inspection.—J. LAIDLEY, *Adare Manor, Adare*.

[The Lichen on the Oak and on some other trees is the *Evernia prunastri*; but there are also other Lichens, as *Borreria ciliaris* and *Usnea plicata*. We would deepen the drains and thin the trees. The drains ought not to be farther apart than 12 feet in such a heavy soil. If the trunks and main branches could have the Lichens removed by scraping it would benefit the trees. After the scraping, wherever practicable, we would pare and burn the top spit of the soil, and spread the ashes over the surface.]

IS A DRY OR MOIST ATMOSPHERE THE MORE CONGENIAL FOR SETTING MUSCAT GRAPES?

IN accordance with the request of your correspondent, "NEMO," I will endeavour to answer the questions asked by him, though it may be in a somewhat simple manner.

He asks, in the first place, at what time the adherent to the steaming process has his Grapes ripe. I think, if he look carefully over my communication again (see page 125), he will find nothing there about a steaming process for Muscats while in flower. The Muscat Grapes referred to are ripe in the month of August; the first bunches that are cut are generally for exhibition.

The next question he wished to have answered is regarding the system of Muscat-growing practised here. On starting the Vines, in the first place we commence with a temperature of from 45° to 50°, rising gradually as the Vines advance in growth, at the same time going through the usual process of syringing and damping. When the shoots have grown from an inch to 3 inches in length, the syringing is discontinued, steaming being carried on till the first flowers are perceived to be opening, then it is discontinued altogether. During bright days, whilst these Muscats are in flower, the passages of the house are occasionally sprinkled. When we see the Grapes are sure to set, then moisture is increased. The temperature

while the Vines are in flower is from 70° to 75° by fire heat, raised to 90° by sun heat.

But we have strayed from the principal part of the question first raised, which was, whether a dry or moist atmosphere is the more congenial for "setting" Muscats; not for the growth or ripening of the Grapes.

We have also another large Muscat house, in addition to that named in my communication already referred to, and which contains eleven large Muscat of Alexandria Vines. These are in flower in the month of May, and the house has the same treatment as the other. Each Vine has to support twenty-four bunches as a fixed number every year, the rest being cut off, and I am sure no one could wish to see a finer house of Muscats for regularity of bunches and berries. The last of the bunches in this house were cut on the 21st of last January, and were fine in condition, but the berries rather shrivelled, although not having the appearance of raisins.

These few remarks and the others previously made by me are not offered for the sake of argument, but merely as facts coming under my notice. It would be as difficult to convince gardeners which is the right road to success—a dry or a moist atmosphere, as it is to convince many which is the right system of Grape-growing, the extending or the restrictive mode.—H. BATTRAM, *Foreman, Cyfartha Gardens.*

AUCUBA JAPONICA.

I DO not know why, but it is so, that frequently the plants, shrubs, and trees, which are so very much belauded on their introduction, seem soon to go out of the thoughts of the gardening fraternity, and I often find that plants there is a rush for at guineas, when they fall to half a guinea or less are heard of no more, excepting when now and then there is a grumbling letter from some disappointed purchaser.

Now, there is the Aucuba with its varieties, great things were promised in its name; no one even writes about this beautiful shrub now, and we are quite in the dark about what is being done with it. When the male plant first arrived in this country we were told it would show itself to be a most valuable acquisition for the arboretum. Perhaps it has not quite come up to the expectations formed of it, and I am told the berries of the female plant do not set well out of doors. Has any one tried it? I will give my experience of it. In the year 1866 I put out two small plants of the female with the berries set. They did not make much progress until about November, when they began to swell; they completed their growth in January, and in spite of the very severe weather, ripened into a beautiful orange vermilion by the end of February, 1867. I sowed the seeds in May, and have now some young plants from them.

Having a young male in bloom in my sitting-room at the commencement of the year 1867, I shook the pollen from it on some writing paper, and then put it from this into a small glass bottle, and when a large female plant that I have had some years in my garden came into bloom some time after, I touched the flower lightly over with a camel's-hair brush, dusted with the pollen from my bottle. The result is that I have now many cymes of large berries just becoming of a fine scarlet colour.

What I wish to draw attention to is this, that we have now the opportunity of making some of our fine old plants of the Aucuba look perfectly beautiful in the spring with so little trouble, as the cold (and I think 1867 should be a test), does not seem to affect the ripening of the berries in the least; mine not only ripened but grew after one of the most severe winters of late years.

Has any one planted out the male and female side by side, and, if so, will they inform me with what success as regards the setting of the berries?—HARRY.

WINTER QUARTERS OF THE RED SPIDER.

In your number of the 19th of December, 1865, the above question was asked by "T. G." As it is one of vast importance to the Peach-fancier, any solution must be acceptable; and the present time being recommended by Mr. Rivers as the most seasonable for amateurs to prune their Peach and Nectarine trees, much of this work will now be going on amongst growers, and I have no doubt that many will by a little observation be able to corroborate my statement.

Last season a few of my Peach trees in 11-inch pots were much infested with the red spider. In December I gave them

all a good dressing with Gishurst compound, 4 ozs. to the gallon, and examined every part of them, and everything about them most carefully, which led me to discover at least one of the winter quarters of the enemy. My trees being young, and trained as perpendicular cordons in pots, of course required stakes, for which I used bamboo split to the proper size, with bast for ties. In taking the old ties off, I found in each piece of bast, just where the knot was tied, myriads of the red-coated rascals, and in every crack in the bamboo they swarmed. I gave a sigh of relief, and was thankful, for I intended to have used the same stakes this year.

I hope the relation of these facts will throw some further light upon the subject, and induce others while looking over their trees and plants not to forget to give an eye to the appliances used about them.—T. L. C.

CATERPILLARS ON GOOSEBERRY BUSHES.

AMONG the many receipts which have been given in your pages from time to time for the cure of this pest, I have not observed one that I have known, and seen used with good effect, and that is fine sea sand. This, if collected fresh every year from the beach, kept from being washed by rains, and sprinkled over the bushes when the grub begins its ravages, will effectually put a stop to them. Any person who may try this simple remedy will rid the bushes of the caterpillars, and, if it be persevered in, will finally prevent all injury.—J. LAIDLEY, *Adare Manor, Adare.*

MUSHROOM CULTURE.

AMONG the plans for securing Mushrooms described in your pages, I have not noticed the simple one of spawning Melon beds at the time of earthing-up. Where there are Melon pits heated by hot water, it is a certain method of securing a continued succession from Christmas to the end of March, a time when they are very welcome. The plan adopted here for I may say the last twenty years, is to insert four or five pieces of spawn along the back and front of a three-light pit, at about 1 foot or 15 inches from the wall. Of course the spawn is covered with the soil used for earthing-up. The pits are filled with Variegated Pelargoniums in the autumn, and all there is to do is to move a few of the pots to give the Mushrooms room when they begin to come through, not much trouble where Mushrooms are an object, and far less than the ordinary care required for beds in a Mushroom house.

This method has always succeeded, even when the beds in the ordinary house have failed.—J. W. K.

[There is nothing new in the method you describe. We have adopted it often in the case of Cucumber beds, as well as Melon beds. When, either from linings of dung, or hot water, the spawn is not subjected to an over-high temperature, when the roots of the Melons or other plants do not run into the spawn, and when the bed does not require to be touched all the winter, then the plan will always succeed tolerably well.

Our objections to its use are the injury done to Melons when the roots penetrate into ground occupied with spawn of fungi; the danger of too much heat to the spawn when linings are used; and the necessity of keeping the bed of soil untouched in the winter months, when otherwise that bed might be used for many purposes. When a bed is so left we have frequently spawned it all over, and kept plants a foot above it on a stage, so as to have access to the Mushrooms easily. As Mushrooms, however, do not require glass for their culture, our own opinion is, that where glass is scarce, it is best to keep the glass for plants, and have a separate bed for Mushrooms. The practice detailed might, however, be suitable to many.]

CHECK TO SLUGS.

LIKE your correspondent, on page 457, December 19th, I have proved the inefficiency of lime, soot, &c., as preventives of the depredations of slugs, but I have never known them pass Barley chaff, hails, awns, or beard, as it is variously termed in different parts of England. From the littery appearance of the material it cannot be used for every purpose; but, of course, every gardener knows where it can be employed. Wherever a circle of it is placed round a plant, inside the rim of a pot, or on the ground, no slimy-coated intruder will pass. When a

neighbouring farmer is winnowing Barley, I beg as much as I think will be necessary, have it run through a sieve, and use it sufficiently thick to prevent any of the slug tribe attacking a plant.—F. FLITTON.

ROYAL HORTICULTURAL SOCIETY.

THE Royal Horticultural Society has not unfrequently been reproached with a want of sympathy for science, and charges have at various times been made that it neither prosecutes nor encourages it. These charges may or may not be true, and their value depends very much on the quarter whence they come, and the standpoint whence the accusers regard the object and operation of the Society. That there is wide scope for the Society to prosecute a course of scientific investigation there can be no doubt, and that the field has not been cultivated as it might have been is equally doubtless; but to say that the Society either ignores, neglects, or discourages scientific investigation as regards horticulture and the laws of vegetation is contrary to fact, as may be shown by a reference to its published Transactions and Proceedings in bygone days, and by the appointment of the Rev. M. J. Berkeley as one of its present Horticultural Directors. It is true that in those latter times, now happily past, when the Society was struggling through a transition state to a new existence, neither practical horticulture nor scientific research received their due attention; but it is unfair, now that it is working with a will in its legitimate field, and doing its utmost so far as its means will allow, to recall the days of its distress, and endeavour to establish against it charges which, however true then, are entirely unfounded now. For the last two or three years the Rev. M. J. Berkeley has been labouring exclusively in the interest of science in connection with the Society, and how useful his work has been is known to many, and indeed to all who have taken the trouble to inquire.

By way of developing more fully its scientific character, the Council announced at the meeting on Tuesday last that they had decided on forming a Botanical, or what may be regarded as a Scientific Committee. As is well known, there have been for many years the Fruit and Floral Committees in full operation. These deal with the subjects that severally appertain to them; but hitherto there has been no similar body engaged in scientific investigation, and it will be gratifying to our readers to know that there will now be associated in the Society a body of men competent to deal with the abstruse and difficult questions which are constantly arising in horticultural practice. The subject will be understood from the following paper issued by the Council:—

"1. The Fruit and Floral Committees of the Royal Horticultural Society have for their objects the encouragement of the production of new and improved varieties of fruits and vegetables, plants and flowers, and the examination of the pomological and floral subjects submitted at the Meetings, or grown in the Society's garden at Chiswick; and these Committees have dealt with the results of horticultural practice brought under their notice in a manner which leaves little to be desired.

"The Fruit Committee have also disseminated reliable information respecting the adaptability of particular kinds of fruits to the varied conditions of soil, locality, &c., throughout the United Kingdom.

"2. At the general Meetings of the Society, the objects of scientific interest which have appeared before the Fruit and Floral Committee Meetings, together with other points bearing on physiology, and the culture of plants and trees, have been regularly brought forward, and occasionally discussed.

"3. The Council now consider it advisable to invite the co-operation of physiological botanists and of chemists in the formation of a Committee, whose special functions shall be, to promote and encourage the application of physiology and botany to purposes of practical culture, and to originate experiments which may assist in the elucidation of horticultural subjects.

"4. The Committee shall consist of a Chairman, who shall be a member of Council, three Vice-Chairmen, and any number of gentlemen, whether Fellows or not, interested in vegetable physiology and horticultural chemistry.

"The three Horticultural Directors are to be considered *ex-officio* members of the Committee.

"5. The Committee shall sit on the days fixed for the general Meetings of the Society at such times and places as may be found convenient.

"The foregoing resolutions shall, as a preliminary step, be communicated to botanists, physiologists, and chemists, with a request for their co-operation as members of the Committee, or as corresponding members."

It will be seen that these resolutions deal with the subject in general terms, and we presume that in a subsequent announce-

ment the details will be gone into more fully. We are glad to see that the constitution of this Committee will not be confined exclusively to botanists and vegetable physiologists, but that chemists also are to be associated. The microscopists also ought to form an element in this new Committee. The revelations of the microscope are not less important than those of the laboratory, and when we consider how valuable both are in union with physiological research, we shall hope to see great results from such a combination.

Among the subjects which come within the province of the new Committee we may instance—1, The examination and elucidation of abnormal structure; 2, The principles and practice of hybridising and cross-breeding; 3, The investigation of sports in form, habit, and colour, and the agencies by which these are produced; 4, The theory and practice of grafting, and the influence of the stock on the scion, and the scion on the stock; 5, To inquire into the origin, nature, and treatment of the diseases to which plants are subject; 6, To regulate and correct the nomenclature of garden plants, and to determine their synonymy; and finally, To institute experiments based on scientific principles, which may tend to secure certain results in cultivation, and to avoid the repeated failures which occur through ignorance of the fundamental laws which govern all organic as well as inorganic matter. These, and many more subjects which will suggest themselves after the Committee is in operation, when subjected to the consideration of such a body cannot fail to have a most beneficial effect on practical horticulture.

This movement has our heartiest support, and we trust it may be successful.

FORTNIGHTLY MEETINGS.—March 3rd.

FRUIT COMMITTEE.—G. F. Wilson, Esq., in the chair. Mr. Davis, market gardener, Starch Green, Hammersmith, sent two packets of Mushrooms, such as he has been supplying to Covent Garden from the same bed since the 1st of September last, at the rate of twenty bushels a-week. They were remarkably handsome and of fine substance, and were much admired by the Committee. Mr. John Glen, gardener to Mr. Palmer, Elmstead, Chislehurst, Kent, sent very good specimens of the Potato Onion. Mr. Davie, gardener to the Marquis of Huntley, Orton Longueville, near Peterborough, sent dishes of handsome specimens of Beurre de Rance and Easter Beurre Pears, neither of which, however, was of good flavour. Mr. Bull, of Chelsea, exhibited specimens of several varieties of Melville's Curled Borecole, which are represented to be perennial; but as they did not appear to differ from other varieties of coloured Borecole in cultivation, and as there was no evidence before the Committee that they were perennial, the Committee decided that they should be grown in the Society's garden at Chiswick before a proper examination of them by the Committee could be made.

FLORAL COMMITTEE.—This was the finest exhibition the Society has seen at the fortnightly Tuesday Meetings, and it is most gratifying to witness the increased interest taken in these Meetings, both by the exhibitors and the Fellows, many of whom are convinced that these gatherings have quite as much, and to some more, interest than the formal great shows.

F. J. Graham, Esq., again exhibited his seedling Violet Victory; he also brought specimens of The Czar for comparison, but they were so badly grown that The Czar was scarcely recognised. The seedling must be seen better grown before it can be noticed. Messrs. Veitch again sent a very choice collection of plants, chiefly Orchids; there were twelve varieties of Lycaste Skinneri, an exhibition in itself; a pretty plant of Dendrobium glumaceum, also fine examples of Hippeastrum pardianum. A special certificate was awarded. W. Marshall, Esq., sent one of the largest and finest collections of Cattleyas ever seen, it was magnificent; the varieties Jano, Cleopatra, and Tricolor respectively received first-class certificates. A special certificate was voted for the group, and the Committee recommended that a medal be awarded for the excellent cultivation of the plants.

Mr. James Atkins, Painswick, Gloucestershire, sent a very interesting collection of hardy spring-flowering plants; among them Iris reticulata, a well-known but extremely pretty flower, also a hybrid Cyclamen—*coom album*, which was awarded a first-class certificate. Messrs. E. G. Henderson's collection contained many very pretty plants; among them an Acanthopanax with variegated leaves; Primula denticulata floribunda; Daphne alternifolia, new; Iris reticulata; Galanthus plicatus, or the Crimean Snowdrop; and two pansies of Pyrethrum Golden Feather, one of cuttings, the other seedling plants, proving that the seedlings come true, and are equal in colour to the parent plant. A special certificate was awarded. Mr. Hannan, gardener to E. B. Evans, Esq., sent a large branch of Bougainvillea spectabilis with highly coloured bracts. Mr. Cross, gardener to Lady Loasia Ashburton, brought a cut spike of Lelia elegans Turneri, very beautiful, with deep rosy purple flowers. A first-class certificate was given for it; also from the same exhibitor came a spike of Oncidium Batemanii.

Mr. William Paul sent a very extensive collection of plants in very

fine condition; also a box of cut Camellias. His Variegated Zonal Pelargoniums were extremely good specimens, and in great variety. He also exhibited some Auehas well covered with berries, some fine specimens of Erica Willmoreana, and a collection of Polyanthus which originated from the common Primrose. These flowers will be found most useful for spring decoration, and are worthy of attention, for by perseverance in their culture a great improvement may be expected. The two varieties, Waltham Primrose and Waltham White, with their circular flowers were very neat and showy. A special certificate was awarded for the Camellias, and another was given for the group of plants.

Messrs. Smith, Dulwich, brought a small collection of their Variegated Zonal Pelargoniums, and among them were some seedlings of first-rate quality. Comet, a yellow ground with broad bronze zone, was very much noticed and admired. A special certificate was awarded. Mr. Standish exhibited three seedlings of Aueha japonica—namely, quercifolia, ileifolia, and crassifolia. When larger plants these will most probably be considered worthy of notice. There seemed to be much distinctive character belonging to each. Mr. B. S. Williams, of Holloway, sent a fine collection of Orchids, containing many fine specimens—among them a fine Oncidium abortivum, the curious flowers of which give a great elegance and delicate character to the whole plant. A special certificate was awarded for the collection.

Mr. Dobson, of Isleworth, sent a large collection of Primula sinensis in every shade of colour. The plants were remarkably well grown, and densely covered with flowers. A special certificate was awarded them. Mr. Richards, gardener to Lord Londesborough, exhibited Oncidium macranthum hastigerum with large yellow flowers, marked all over with brown spots or stripes. A first-class certificate was awarded it. Mr. Moore, gardener to the Earl of Shrewsbury and Talbot, sent a collection of cut Orchids, among them a fine spike of Odontoglossum Alexandra, for which a special certificate was awarded. It was presented to Her Royal Highness the Princess of Wales. J. Day, Esq., sent some very fine Orchids, among them Odontoglossum Bluntii, O. gloriosum, and O. intermedium, which received a first class certificate; also Cattleya Mossiae superbiissima, a fine purplish rose flower. A special certificate was awarded the collection. Major T. Clarke brought some cut specimens of flowers, Orchids and others, among them Pelargonium semperflorens, a very pretty delicate flower—a special certificate was awarded. Messrs. Osborne, Fulham, exhibited a pretty group of well-grown plants. A Rhododendron covered with flowers was very beautiful, and the collection of spring flowers, exhibited in a basket of moss, was much admired. A special certificate was awarded. Mr. Dean, Ealing, brought a plant of the dark-red flowering Primrose, not unlike many other seedlings.

GENERAL MEETING.—W. Wilson Saunders, Esq., F.R.S., in the chair. After the usual formal business, and the election of eight new Fellows, the Rev. M. J. Berkeley proceeded to notice some of the most remarkable subjects exhibited.

Mr. Berkeley said that at the last meeting he had directed attention to an extremely pretty Gongora, which was unnamed, and he had since found it to be a variety of Gongora maculata, described by Dr. Lindley in the "Botanical Register" in 1847 under the name of G. bufonia leucochila, but at the end of the same volume identified as a mere variety of G. maculata, being there named G. maculata tricolor. There were also at the same meeting two or three Thuja—viz., T. Zuccarimiana, T. fakata, and Juniperus japonica, about which his opinion was asked. The other evening he was at the Linnean Society's, and there he saw a collection from Dr. Hooker, and in it he could find no trace of such a plant as T. Zuccarimiana. Juniperus japonica he believed to be the same as J. chinensis.

With reference to the beautiful collection of Cattleyas from Mr. Marshall, the whole he believed were varieties of Cattleya Warscewiczii. He next directed attention to Dendrobium glumaceum, with a spike resembling that of a Grass, and to the fine example of Oncidium macranthum hastigerum, from Lord Londesborough's gardens at Grimstone Park, and Mr. Pierce had informed him he had found the same variety some years ago in the neighbourhood of Quito. The white Cyclamen cornu and Iris reticulata, from Mr. Atkins, were then mentioned, also the Crimean Snowdrop, to the beauty of which, however, the specimens sent did not do justice. After noticing the very elegant flowers of Hottelia japonica, plants of which were shown by Messrs. Veitch, Mr. Berkeley remarked of Primula denticulata floribunda, shown by Messrs. E. G. Henderson, that the size of the trusses depended on the lateral fusion of the footstalks. A plant with very ornamental leaves 14 inches long and 9 inches wide, and supposed to be a Begonia, exhibited by Mr. Wilson Saunders, was then referred to as being one of the most interesting plants in the room, and, though nearly allied to the Begonias, probably belonging to a distinct genus. With regard to Skimmia odoratissima, of which a plant was also shown, Mr. Standish had informed him that in raising plants from seed he had found that the male plants were identical with odoratissima, and the female with oblata, and the conclusion, therefore, is that the two are merely the different sexes of the same species. Mr. Berkeley then brought under notice some cut Rhododendron flowers, produced in the open air in Denbighshire, and which had been sent by a friend of his, with whom on the late the Rhododendrons were a sheet of beautiful flowers, whilst at Abercrombie, on the mountain limestone, they failed almost entirely. At the last Meeting

he had read a letter respecting the damage done to the woods at Adare Manor, in Ireland, by Lichens. People naturally wish to know how it is that Lichens do so much injury to trees. Their mycelium does not enter much into the tissues, or when it does, seems to be on extremely good terms with them. In Cinchonas, for instance, which were so attacked, the medicinal properties of the bark were stronger. The popular opinion was that Lichens injured trees by feeding on their sap, and Shakespeare, in the Comedy of Errors, has

"Usurping ivy, brier, or idle moss,
Who, all for want of pruning, with intrusion
Infect thy sap, and live on thy confusion,"

by idle moss meaning Lichens. For his own part he believed that though, like some parasites, they obtained certain substances from the bark, the injury which they did was chiefly by their depriving the plants of the access of air and light.

Another subject which he wished to mention was that at the last Meeting he was shown a piece of wood affected, it was thought, by dry rot. Now, there were two forms of dry rot, the one produced by a fungus, Merulius lachrymans, the other not; and in the one case there was a remedy, in the other none. The fungus could be destroyed, or rather its progress checked for some years, by corrosive sublimate, although decay, as in the case of kyani-ed timber and railway sleepers, would ultimately take place. The other form of dry rot was a kind of slow combustion, called eremacausis, in which oxygen combines with the combustible portion of the wood, namely hydrogen and carbon. Now, taking wood to consist of thirty-six equivalents of carbon, twenty-two of hydrogen, and the same of oxygen (C₃₆, H₂₂, O₂₂), the withdrawal of one equivalent of carbon and two equivalents of oxygen for the formation of carbonic acid, and of one equivalent of oxygen and one equivalent of hydrogen, forming water, would reduce the proportion borne by the oxygen and hydrogen to the carbon; and if the withdrawal of the last two elements were continued, it was a question whether carbon only would not be left. After referring in connection with this subject to the recent discovery of a new acid, called xylic acid, in the decayed matter of the trunks of trees, Mr. Berkeley read an account of some trees on a wall covered with a galvanised wire trellis, and in which it was stated that the shoots appeared scorched, and were killed where they came in contact with the wire. One explanation of this occurrence might be the variations in the temperature of the wire at different times; another, that galvanised wire being rough, would, no doubt, fret the shoots where they touched it, and the expansion and contraction of the wire would alone be a constant cause of this fretting. In confirmation of the latter view, it was mentioned that at Chiswick, where smooth, painted wire is used the trees were not injured. After noticing a fine branch of Aueha japonica covered with berries, sent by E. A. Brande, Esq., Sulhamstead House, Turnham Green, as justifying the prophecies made on the introduction of the male plant, Mr. Berkeley directed attention to some exceedingly well-executed water-colour drawings of plants, made by Mr. F. W. Burbidge, one of the Chiswick students, and which showed that the Society had taken an important step in the right direction when they had determined on admitting students at the Chiswick garden.

Mr. Wilson Saunders said that before the Meeting closed he wished to draw attention to Sempervivum holochrysum, on account of its handsome spike of yellow flowers being so showy at this time of year. The plant was of very easy culture—in fact, it was almost impossible to kill it, in proof of which he said he had put a stem of it aside to dry for his museum, and though it dwinded for awhile it again grew after several months. There were five or six other Sempervivums, which came from the Canary Islands, and he would be happy to give to the Fellows cuttings of the one his gardener had shown. Referring, then, to the fine collection of Cattleyas exhibited by Mr. Wilson, Mr. Marshall's gardener, he said they were all imported plants, and though it was not known why they produced such different colours in their native country, it was necessary to be very careful of attributing anything specific to colour, for it was very unsafe to do so. All who were present at the Meeting must feel very much indebted to Mr. Marshall for bringing such a collection; but however different the flowers were, he (Mr. Saunders) thought he could discover five or six so-called species, which would have to be cut out of the list of species. After remarking that a peculiar and fine tint of yellow had made its appearance among variegated plants lately, and that he could not tell why we were getting this peculiar colour, he said that he had now to direct attention to the fact that the Council, in their desire to promote scientific horticulture, had, in addition to the Fruit and Floral Committees, both of which did their work admirably, resolved on having a third Committee, the objects of which have already been fully set forth in a previous column. By the next Meeting (March 17th), Mr. Saunders hoped that the organisation of the Committee would be sufficiently advanced for the names of the members to be announced. It was not intended that they should exclusively consist of Fellows of the Society.

Major Trevor Clarke said there were two Lichens growing on the front of his house, one of which corrodes the stone, whilst the other, if scraped off, leaves the stone intact; probably Mr. Berkeley could tell him the names.

Mr. Berkeley declared his inability to do so without examining them, but named two which were likely to be found in such a position.

Major Trevor Clarke having offered a few bulbs of Calanthe vestita for distribution, the proceedings came to a close.

Although not announced at the Meeting, we may add that the amount already subscribed as special prizes for the Society's Great Show at Leicester in July next, already exceeds £370.

THE ROYAL HORTICULTURAL SOCIETY AND ITS GARDENS.

I WAS at first somewhat taken with a measure proposed in your contemporary's issue of last Saturday week (*Gardeners' Chronicle*, page 181-2), to convert the greater portion of the Chiswick establishment into a "utilitarian" or market garden; but I doubt if it would do. It may be asked, Why not convert it into a nursery garden? Trees, shrubs, and plants would prove more remunerative than Apples, Gooseberries, and Peas, and therefore "in the name of common sense," as your correspondent says, why not go in for the most paying trade? This shoe, however, would manifestly pinch somewhere, and the Society would soon find out that it had put its foot into it; for, whilst your correspondent thinks that market gardening is a perfectly legitimate and praiseworthy occupation for it, he objects to the gift of a few trifling packets of seeds to the Fellows, on the ground that "it is entirely unworthy of its high character that it should compete, as it were, with nurserymen for the supply of the private gardens of the Fellows with common seeds for the kitchen or flower garden." But surely, Mr. Editor, it is equally unworthy of the Society's position that it should scramble with market gardeners, either for the supply of the tables of the Society's Fellows or of any other fellows! And therefore I fear that the market-gardening business cannot be thought of as an opening for the discharge of its "high function of teaching the art and science of horticulture by precept and example" any more than the nursery business, though the remark of your correspondent that "respectable nurserymen abound," suggests that seed and plant selling must be an uncommonly good trade.

On reconsideration, then, it appears pretty clear to me that the Society must neither grow Orchids nor Potatoes simply with a view to sale, but continue its energies (while giving a fair field and no favour both to market gardeners and nurserymen for competition with each other), to such measures as will advance the highest interests of horticulture. Nobody will object to the Society's disposing of such produce as the garden yields in the legitimate way of its work, either to Fellows or in Covent Garden Market; and I can hardly believe that our Riverses and Pauls, our Veitches, Lees, and Standishes, grudge to the Fellows the privilege of receiving a few packets of seeds annually, because a few pounds are thereby lost to the trade. If these gentlemen think of the matter at all, they probably regard what your correspondent terms such "excessive liberality" rather in the light of an incentive to horticultural tastes, and in the long run as productive of benefit to their business. I like to have my seeds, I confess. I watch their growth, and talk of them to my friends with far greater pleasure than of those I get from Messrs. Carter; and on the same principle I prefer eating eggs laid by my own fowls, or butter made from the milk of my own cow. I look upon Chiswick, in fact, as in part my own property. I will not deny that there may be a *souperon* of a meaner motive—viz., the pleasure to be derived from getting my money back again; and I am inclined to think that with many of the Fellows this motive is sufficiently strong to induce them forcibly to resist such a curtailment of their privileges as he recommends.—COMMON SENSE.

P.S.—I have always told my friends that the Society's "Journal" was very learned; that it is edited by Mr. Berkeley, who, like the Society, has a European reputation. Am I right, or ought we to be ashamed of it, as the correspondent of the *Gardeners' Chronicle* states? Please tell me.

[Let us charitably suppose that the writer has failed to distinguish between the Society's "Journal" and the *ephemeris* issued periodically from the office of the Society. That any person should be "ashamed" of what emanates from Mr. Berkeley's pen, or editorial supervision, is to acknowledge himself incompetent to form a judgment.]

ORNAMENTAL AND FLOWERING SHRUBS.

(Continued from page 166.)

COTONEASTER MICROPHYLLA.—Leaves small, dark green; procumbent habit; flowers white, in summer, succeeded by a profusion of red berries. Very ornamental, suitable for covering walls, rockwork, or banks, and for plantations not very much shaded.

Cotoneaster luxifolia, **C. rotundifolia**, and **C. thymifolia** are similar and desirable species, 2 to 5 feet. Seeds and layers. **C. microphylla**, **C. buxifolia**, **C. thymifolia**, and **C. Wheeleri** form drooping heads when grafted on the *Crataegus*.

COTONEASTER SIMMONSI.—Leaves much larger than **C. microphylla**; habit erect; flowers white, in summer, succeeded by a profusion of large red berries. Very ornamental and desirable. 5 feet. Seeds.

CRATEGUS PYRACANTHA.—Leaves entire, of a deep green; flowers white, in large corymbs, succeeded by bright red berries or fruit, having a fine effect in autumn. Very suitable for covering walls. 6 to 10 feet. Seeds and layers.

CISTUS PURPUREUS.—Flowers large, reddish purple, in summer; shoots reddish, giving the plant a handsome appearance. It is a hardy and very ornamental shrub, and so are **C. populifolius**, **C. ladani-folius maculatus**, **C. laurifolius**, **C. corbariensis**, **C. algarvensis**, and **C. villosus**, but except in dry warm soils and situations they do not succeed. Limestone soil is most suitable. Height 3 to 4 feet. Seeds sown in heat in light soil, and grown on in a cold frame. Propagation is likewise effected by cuttings of the half-ripened wood in sand in a cold frame or under a hand-glass, with shade from bright sun; also by layers.

DESFONTAINEA SPINOSA.—Leaves holly-like, of a bright green; flowers trumpet-shaped, large, red, and very handsome. Cuttings. A very desirable shrub of holly-like erect habit.

ESCALLONIA MACRANTHA.—Leaves oblong, deep green, shining; flowers reddish purple. Altogether a splendid shrub, but needs a warm situation or a wall. Height 6 to 8 feet. Propagated by cuttings of the ripened young wood in heat. The flowers are produced in autumn.

ESCALLONIA RUBRA.—Leaves shining; flowers red, pendulous, very fine, in autumn or late in summer. Warm situation or wall. 6 feet. Cuttings.

ESCALLONIA FLOERIBUNDA.—Leaves oblong, shining, very ornamental; flowers white and numerous, late in summer and in autumn. In most situations requires a south wall. Height 6 to 10 feet. Cuttings.

GAIERIA ELLIPTICA.—Leaves shining, deep green; flowers greenish yellow, numerous, and produced in long, drooping catkins, in winter. Height 6 to 8 feet. Cuttings of the half-ripened shoots under a frame or hand-glass. Requires a warm situation, or protection in winter in cold situations. A very ornamental shrub.

HYPERICUM CALYCINUM.—Leaves dark green, ovate, large, dotted here and there with transparent dots; large yellow flowers, produced in summer. Suitable for planting in shade, making a fine covering under large trees. Division of the roots, which creep. It does not exceed 1 foot in height.

ILEX AQUIFOLIUM, the common Holly, is very suitable for planting in shade, and very ornamental everywhere, making the very best of hedge plants, and bearing cutting well. **I. angustifolia**, **crassifolia**, **myrsinifolia**, and **ciliata** have small leaves; **I. balcanica**, **Hodginsii**, **glabra**, **altaclaren-sis**, **maderensis**, **Shepherdii**, and **nigrescens**, with broad leaves, are very fine sorts. **I. Donningtonensis** is the best of the long-leaved kinds, and is very distinct. **I. tarago** and **I. latifolia** have very large leaves, nearly if not quite as large as those of the common Laurel, but they are rather tender, and should have sheltered situations. The Weeping Holly is very ornamental, and the Silver-variegated Weeping variety is equally desirable, forming a very handsome head. There are many varieties of variegated Hollies which may have their admirers, but the majority of them are very dull in their markings. The Gold and Silver-margined are the most distinct. Hollies are very handsome; standards or clear straight stems from 3 to 6 feet in height, and with well-shaped heads, are very fine, and pyramids are so easily kept in shape by cutting before growth takes place as to be very desirable for architectural and terrace gardens. Grafting on the common Holly.—G. ALLEY.

(To be continued.)

THE MISTLETOE.

ALLOW me to say a few words as to the trees I have seen the Mistletoe growing on, and the localities in which it is found.

Hampshire seems to be a county in which it is met with in large quantities, and the Lime tree appears to be most favourable for its growth. At Swathling Grange, near Southampton, there are some noble Lime trees, and they are literally covered with Mistletoe, and some bunches, I imagine, are quite 5 feet in diameter. Another place where it used to be growing abundantly was in an Apple orchard belonging to, I think, the Dean of Winchester, situated at Bishopstoke, six miles from Southampton. Some of the Apple trees were heavily laden with it, and, perhaps, are so now. At Stratton Park we had an old Maple tree, on which it grew in large quantities, and I have seen it growing on the Lime tree near Earsham Hall, Bungay, Suffolk, but not to the same extent as at the places before named. When at Gillingham Hall I inserted some berries in a cut in the bark of an Apple tree. The seed germinated, and the plant grew about 2 inches, when, by accident it was knocked off. I have also seen the Mistletoe as a standard, and a very pretty standard it made. It was in the pleasure grounds at Eagle

House, Clapham, Surrey. I believe my friend Mr. Freeman (the gardener there), told me it was on an Apple stem, about 3 feet 6 inches or 4 feet in height, straight and clean, and the head of Mistletoe healthy and compact.—T. BATTERS, *Gardener to C. Castleman, Esq., Glasshazes, Lyndhurst.*

TRELLIS ON A WALL.

A PLAN which is followed by our gardener, and which I have never before seen, for fixing laths to a wall for training trees on, is so firm, easy, and good, that I am sure many of the readers of THE JOURNAL OF HORTICULTURE will be glad to know about it.

The nails used are merely pieces of soft iron of the shape represented in fig. 1, and which can be made by any worker in

Fig. 1.

iron. The size for laths of the ordinary thickness used on walls is 4½ inches long, and half an inch wide at the widest part, and the iron is about one-eighth of an inch thick. The tool for fixing them is a kind of key, made of steel, of which I give a side and end view (fig. 2). It is about 8 inches long, and 3 inches round at the thickest part.

Fig. 2.

The size of the nails and that of the holes in the key agree; the end of the nail is inserted in the end hole of the key, and driven into the mortar by striking the other end of the key with a hammer. A hole of the requisite size is then made through the lath with a gimlet. The nail in the wall is put through it, and the projecting portion firmly clenched. A long lath will not require more than two fastenings. The plan is known to few; but in one garden near here there are laths so fixed which have been in use for forty years.—E. WATTS.

WORK FOR THE WEEK.

KITCHEN GARDEN.

If the successional crops are sown at the first favourable opportunity the permanent ones will not suffer much by the delay of a week or ten days if the soil is not in a fit state; and if time is taken to do the work in a proper manner it may prevent loss of time and disappointment afterwards. *Asparagus*, where this is forced regularly a few rows must be sown annually to keep up the supply. Any time this month will do for the sowing. *Artichokes*, it is a good plan to plant out, every year, during the month, a few rows of suckers; these will produce after the permanent ones have done bearing. An equal number of the older stools may then be destroyed annually. Plant them in single rows. *Horse-radish*, this should be treated exactly like the Artichoke, by planting a few rows annually, and trenching up the oldest bed, picking up every morsel of the roots. Plant late Potatoes rather thickly in the bed, in order to destroy what remains of the roots. *Peas and Beans*, it is a good plan to sow early and late sorts at the same time, to prolong the succession; but rather sow often than a large breadth at one time—say every other week till the end of April. The forced Peas should be planted out when all danger of severe frost is over. *Rhubarb*, this should be planted without loss of time, where new plantations are wanted or any new sort is to be tried. Do not trust to seedlings from superior sorts, they sport as much as Broccoli. *Sea-kale*, either sow a few rows, or plant cuttings from the crowns.

FRUIT GARDEN.

The chief business here is to provide coverings for the Peach and Apricot trees, and any of these which are not yet nailed must be attended to forthwith. Whatever covering is used it should be made to lift up during the daytime. More harm is often done by close-fixed coverings than when the trees are not protected at all.

FLOWER GARDEN.

If it is not decided with what plants the beds in the flower garden are to be planted this season, the sooner the decision is made the better. Autumn-sown annuals may now be removed to their blooming places, planting three or five in a patch according to the kind and size. For beds intended to contain

half-hardy plants, annuals planted in a line round the outside, and pegged or clipped into shape, form a neat and gay edging in the early part of the season, and leave the centre of the beds to be thickly planted with such plants as are intended for summer and autumn decoration. Californian annuals, such as *Clarkias*, *Collinsias*, *Leptosiphons*, *Nemophilas*, &c., sown now will bloom almost as soon as those sown in autumn; indeed, it is advisable to sow a few at the time of planting, as they fill up all vacancies, and prolong the season of bloom. Herbaceous borders, if not dressed over in the autumn, must be attended to immediately, and either fresh compost or manure must be afforded all plants which are weakly. Proceed with the planting-out of biennials of all kinds, and prepare a good-sized piece of ground for a sowing of *Anemone coronaria*, *hortensis*, and *vitifolia*. *Anemones* delight in a strong rich soil, and a rather shady situation in summer. Sow the seed, after well rubbing it in sand, in shallow drills 9 inches apart, and cover with rich soil from the compost yard. A sowing of Ten-week Stocks must also be made on a warm sunny border; cover with litter or mats at night until the seeds begin to vegetate. Sow, likewise, a general assortment of annuals for transplanting to fill up vacancies. *Auricula* seed may now be sown; the best compost is sandy peat and leaf soil. Shallow boxes or pans should be filled nearly full, and watered well to make the soil settle; the seed may then be thinly sown on the surface and covered very slightly. The blooms are now rising; take care that the trusses be not drawn by keeping the lights on too much. Still keep a sharp look-out for snails among the *Polyanthuses*. With a small hand-fork keep the surface of the bed loose, taking care not to disturb the fibres; if grown in pots the soil must be occasionally stirred, keeping them moderately moist. If the fine days last week were taken advantage of, many *Ranunculus* beds will have been planted; if not, the sooner the better. The beds of *Tulips* must be carefully gone over, and the cracks filled up, putting the soil firmly round the neck or rising leaves. *Carnations* are now beginning to grow, and diseased plants which have struggled through the winter thus far are dying off. All vacancies in the beds of *Pinks* must now be made up, and the soil kept in a loose friable state on the surface. Look well to trapping wireworms and other enemies.

GREENHOUSE AND CONSERVATORY.

As a large number of spring-flowering plants are now coming into bloom in the conservatory, more air must be admitted; but those recently removed from the forcing pit, and all stove plants brought into bloom, must be arranged in the warmest part of the house. Fresh beds of soil should now be made for climbers that are to be planted this season, and a portion of the old soil removed from such established ones as are known to quickly exhaust the soil, replacing it with a fresh supply. This will be a good opportunity to cut or root-prune such climbers as have rambled over the houses without flowering much for the last year or two; and where duplicates exist this is a suitable time to cut down some of them to the ground, in order to prolong their flowering season. This is the best plan to adopt with plants infested with the scale or other troublesome insects, if care is taken to clean the remaining portion of the plants, and the pillars or trellises to which they have been trained. It is now a good time to propagate greenhouse plants by cuttings where a gentle bottom heat can be maintained. Great attention is required to keep these plants from growing too fast at the present season; the least confinement is injurious to many tribes of woody plants in this department. The tops of young plants in free growth ought occasionally to be cut off, in order to make them good bushy specimens, even if their bloom is sacrificed at this stage.

PITS AND FRAMES.

Here the work need not be pointed out. The means of providing room after the plants are potted is the greatest difficulty in most gardens. Glazed calico is sometimes used to protect plants when potted-off. Choice annuals, such as *Brachycome iberidifolia*, *Viscaria oculata*, *Mesembryanthemum tricolor*, *Portulacas*, *Clintonias*, and the like, should always be potted-off as soon as they are sufficiently large to handle, and afterwards be placed in a warm moist atmosphere, with plenty of air in mild weather, until they are properly established.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Just before the rains of the 29th ult. we took up most of our Celery, as we wanted the ground for Onions and other crops.

We took the Celery up with good bafis, watered it at the bottom, and banked it up rather closely on a level bed of sifted furnace ashes. We have thus kept it in good condition in a shady place until April or May, and it requires little trouble to take it for use. The only objection to the plan is, that unless the Celery is in a walled garden it must be protected with wire netting from marauders.

In connection with this subject we may state that wire netting, 2 feet in height, placed against an open fence of Ivy, secured our Cabbage plants from rabbits until lately; but we now find we ought to have had the wire farther from the fence. A number of fine plants have been cut up, and on close inspection we discovered that the rabbits had mounted the Ivy fence, and from thence jumped over the wire. When people want to be very sure, a 30-inch fence would do better than a 24-inch one, as the following fact will show. Outside the garden a heap of rotten leaf mould had been piled against a low wall. The highest part of the mould was 20 inches from the coping; yet to that coping the rabbits had sprung, and then dropped down a depth of nearly 6 feet inside, as proved by the excrements and hair left behind them, and the marks of their feet and bodies in both positions. We have seen a hare spring, when pressed, a height of 9 feet; and we have seen rabbits jump from a good elevation; but we never before knew them to get up and over a wall nearly 2 feet above where they could stand.

Planted early Potatoes at the bases of walls, and placed others where there was a little heat to sprout them an inch or two. Planted the pit with the strong plants of Cucumbers referred to last week, and Saturday being a wet day, pricked-off a lot of Celery into shallow boxes, which we will place in the hotbeds or Cucumber pit. Of course, before planting the Cucumbers, we had the soil well warmed first.

Avoiding checks of all kinds is the best safeguard against the attacks of insects, and consequent premature decay. Farther on in the season such care would be less necessary; but at present every moving of the Cucumbers from the dung frame, whether for potting or final planting, was done by placing the plants as quickly as possible in a close box during the little time taken in the transition from one place to another. We mention this not to remind experienced professional gardeners, but as a hint to amateurs and beginners to beware of checks. We have known many failures, and therefore as lessening enthusiasm worse than mere disappointments, in the case of Cucumbers, when, after good plants were obtained from a gentleman's garden, and carefully carried home with many wrappings about them, they were unpacked in the open air, allowed to remain there for some minutes, and then, perhaps, turned out and planted at once in soil considerably colder than that they were used to. All such plants should, if possible, be unpacked in the place they are intended to grow in; and in general it will be as well to water and syringe with water at about 80° or 90°, and leave the plants turned out of their pots for a day at least, and considerably longer if the soil is not warm enough. Such delay and care will be anything but time lost.

Simple as this caretaking is, it is often considered as a matter of no moment. Some seasons ago, in a cold day in the beginning of March, we accidentally noticed in a rather close cold shed thirty or forty fine Cucumber plants, just shifted into 5-inch pots, brought from a hot place, and intended to go in a fortnight into a Cucumber house. We were told the plants had been there more than an hour, as the man who was potting them had been obliged to leave them for another job. We were not surprised to learn that these plants never answered the results expected from them, and that another set of plants had to be introduced early in summer. We could see at a glance how it was. The worker was no doubt a very systematic man. A certain number of plants had to be potted, and potted in this shed as most likely the most suitable place to do the work in; and therefore, on system, all the plants must first be carried out, and then all must be potted, and the group well looked at before any were returned. This would have been the case if there had been no calling-away to attend to the wishes of the lady or anything else. This over-systematising, so as to have a potting shed full of potted plants, is a very favourite system with many young cultivators. It may proceed from the otherwise laudable desire that their work should be seen. Now we think that the better, if less showy, system as respects the Cucumbers referred to, would have been more attention to some little matters; and we specify them for the use of beginners, merely presuming that the plants are

in a frame or pit, where there is no room to pot them. Before potting, have suitable soil properly warmed over a furnace or otherwise; pots cleaned, drained, and also warmed; have warm water also in readiness. Then bring only a few plants out at a time, shift, or do what is wanted, and afterwards as quickly as possible take them back to their warm place, and bring out a few more, and thus go on. If on an emergency the work must be left, the plants can be so replaced as to receive no injury.

We might tell a similar tale of hundreds and thousands of tender cuttings inserted with much care in February or March, and yielding but a poor return in rooted plants, and this chiefly because the danger of checks was considered to be of no importance. Now the only secret in striking a growing cutting, is just to keep it growing, and never allow it to have a check or a flagged leaf. But for the courtesy of the affair, and the pleasure it yielded, we have often thought it was labour thrown away to take off cuttings, and give them to people who unceremoniously stuffed them in their pockets like so many little bundles of straw. Some years ago we noticed a nice hotbed filled with cutting pots, but mostly empty, or covered with the dead and dying cuttings, and we learned something of the reason. About two hundred varieties were thus to be largely increased for bedding purposes, and the cuttings were taken as they were growing rather tender, in a house ranging from 60° to 65°. On the system referred to, all the cuttings were taken off first, and laid down with their little tally to each kind, on a bench in a cool shed. Then pots partly prepared had to be made ready, then the cuttings had all to be made, and when made all had to be inserted before being placed in the striking bed, and thus the little tender cuttings were shrivelled, starved, and almost dead before they were placed in suitable quarters. A less showy, but a far more suitable system would have been to do a few pots at a time, and put the cuttings in their place at once. Such few pots could easily be filled in the house where the cuttings were taken from, if no warm place could be obtained.

FRUIT GARDEN.

Pruned out of doors when we had an opportunity. Placed more Strawberry plants in pits and houses. We shall not be so early this year as usual, as we have not begun so early. The most forward are showing well. One of the secrets of success, provided the plants were fair for strength and ripeness last autumn, is to avoid extremes of temperature, and commence with a low temperature, and rise gradually. A heat of 55° or 60° is quite as high as the plants ought to have until in bloom, and the fruit set; from 45° to 50° will be high enough to begin with. For want of tree leaves we could not start them in frames as we wished to do. This is an excellent plan for starting the plants, provided the heat is mild, and the roots do not find their way through the bottoms of the pots.

Our stock of Strawberry plants is under the protection of the orchard houses just now; but they received much more wet in the autumn and in the beginning of the winter than we liked. However, we do not think the wet, nor the frost which they had up to nearly Christmas, has done them much harm. The pots stood on the hard ground unplunged, and in some of the severe frosts they were covered all over with litter for a week. On turning out a number of pots before housing them, the roots were all as they ought to be—fresh, growing, and clinging to the sides of the pot. This would not have been the case but for the litter. We think Mr. Rivers some time ago, after the remarkably severe winter of 1860-61, wrote about how little litter would preserve plants from injury if close to the ground. The above fact as respects Strawberry plants in pots, and many other instances, confirm his statements. Nevertheless, if we had it in our power, we would have Strawberry pots for forcing under protection from frost, rain, and snow by the middle of October.

Regulated Vines breaking, thinned-out superfluous shoots from others more forward; gave heat and air as lately stated. Thinned shoots in the Peach house, watered borders; potted Peas, and took them into it for a fortnight to establish them before removing them to the orchard house. Potted Melons in larger pots, as the bed is not ready for want of material, and we do not wish to have the plants checked. Finished whitewashing the orchard house; and on the 23th, as the day was wet, painted the most of the trees with lime, soot, and sulphur, merely as a precaution. Previously the weather was so fine for out-door work that we did not like to do this before, though this last house would have been as well if thus treated a fortnight ago. The first house, which we bring on earlier, was

finished some time since. If we have a wet day next week we shall scrape over the floor between the pots, so as to remove the surface, though only for a quarter of an inch in depth. We do this by way of precaution, though we had scarcely the appearance of an insect there last season. We shall then prick over the ground with a fork, chiefly to receive water, but not to loosen the soil, except the mere surface. We shall add a little rotten dung, and then water with manure water, doing 2 or 3 feet in width at a time, so that the trees against the back wall may not have too much water at once. The trees in pots being rather dry, watered them, but not heavily, to encourage the fibres to come to the top compost. In another year, if we keep these trees in pots, we must try and shift them early in autumn, as they have been a number of years in the same pots. We have proved what may be done in this way, and a pretty amusement it is for amateurs and ladies. In practice, when a gardener's hands are full, the watering which these trees in pots require is a great drawback; but it is very pretty to see a number of such trees in pots healthy and well loaded. The labour of watering in summer is lessened by repeated mulchings.

Before the blossom opens our aim now is to retard the opening, and thus be more independent of the weather if we should have a frosty March. To help to retard, in some very bright days we spattered the roof outside with water merely whitened with whiting. The syringe in the hands of a man who can use it, will do this for the roof of a large house sooner than we can write about the doing of it. In favourable weather we give all the ventilation we can day and night, shutting up in nights likely to be stormy. We think it is a mistake to hurry on these unheated houses in February; but even if they should be rather forward by giving less air than we have done, the blossom will suffer little from cold so long as the air inside is dry and rather still. We prefer, however, to keep the trees back now, and to help them on by shutting up earlier after the fruit is set. In different houses there will be thus successions without artificial heat, as the house earliest one season will come earlier every season afterwards.

ORNAMENTAL DEPARTMENT.

In addition to what was stated last week about potting plants, we would like to secure a number of Pink and Perpetual Carnation cuttings for next winter; the latter if struck and potted early requiring no forcing to bloom in winter, and the former but little. We have put in a good batch of Verbena cuttings, and would have in cuttings of many other plants could we empty our places of the plants that we are yet afraid to trust with protection without glass. When a single little wooden box, in which Pelargonium cuttings were inserted, now holds from fifty to a hundred fine plants, the potting of thousands and transferring them as stated lately to a Vine border covered with old sashes, makes but little room in the place where the handy boxes stood.

Pricked-off numbers of Lobelias in shallow boxes about 2½ inches deep. These little boxes, made for very little in bad weather, where pieces of wood can be obtained, or old boxes, which are often plentiful and fit for little else but firewood, are better than pans square or round, as they are so much lighter and less likely to be broken, and take up no time in preparing them for such purposes like pots. Then, for pricking-out such little plants, as the bottoms and the sides do not fit over-closely together, no holes for drainage are required. A little rough leaf mould is spread along the bottom, fresh sandy soil rather rough over that, and then a surface of lighter finer soil with a little fine leaf mould in it, pressed down, and pricked all over with the little plants. When well established these can be taken out in lumps with all the roots near at home. Preparing such boxes is a good job for a wet day. To secure neatness and keep fungus away, we generally whitewash them with quicklime, outside and inside. A large number of such plants will be stowed away in our Cucumber beds and frames; not but we would rather be without them, and let the Cucumbers have all to themselves; but, then, if we have them at all it must be by a cramming process. It is important, however, to prevent the plants crammed-in injuring those intended for a more permanent residence.

We intended making some remarks on propagation, but must defer them, as those seeking the information will not be able to begin until after the middle of the month. Meanwhile we would advise a sweet heat in the top of the bed, if bed is to be used, and a good-sized cutting instead of two small ones. Thus, though you may split Verbena stems and make a cutting of almost every joint, or even two cuttings, we advise that each

cutting should have at least two joints, and if a terminal or side shoot, which we like best, that the cutting should be from 1½ to 2 inches in length. Beginners will find that the best.

With regard to sowing tender flower seeds, referred to last week, for all small seeds sown in pots, it is a good plan to fill the pots one-quarter full with drainage, one-quarter more of rough materials, then finer soil, and finer still next the surface, that surface being nearly an inch below the rim. Water well, and leave for the best part of twenty-four hours, then level the surface, sow, sprinkle with a little sand, press gently, take to the bed or warm place, cover with a square of glass, and on that place paper or any other covering, and in general little watering will be wanted until the seedlings appear. If glass is not at hand in little squares to cover the pots, covering all the pots with a newspaper or a cloth until the seedlings appear, so as to keep in moisture, will be safer in such a case than using the watering pot. When that is essential before or after the seeds appear, use no rose, but sail the surface by pouring the water on a piece of tile or crock. Thousands of such little seedlings are ruined from watering overhead with the rose of a pot, however fine the rose may be.—R. F.

COVENT GARDEN MARKET.—MARCH 4.

Our supplies are a full average, and owing to the fine open weather are much better than they usually are at this period of the year. Continental produce is rather lower in price, but home-grown articles are at last week's quotations.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.

N.B.—Many questions must remain unanswered until next week.

BOOKS (H. G. C.).—"The Fern Manual" can be had free by post from our office if you enclose 5s. 4d. with your address. It contains directions for cultivating Ferns in all situations.

RHUBARB FOR MEDICINE (*Rusticus*).—The common garden varieties do not yield the root known as Turkey Rhubarb, and used in medicine. The following extract is from Hogg's "Vegetable Kingdom":—"It is generally believed that *R. palmatum*, undulatum, Rhipidontium, and australe are those from which the commercial supply is obtained. Rhubarb is produced abundantly in the elevated lands of Tartary, Chinese Tartary, Thibet, and Ehotan. It is not cultivated, but springs up spontaneously, wherever the seed has been distributed in places favourable for germination. The root is not considered fit for use till it is six years old, when it is dug up twice a year—in Tartary in spring and autumn, and in China only in winter. When it is taken up, the bark is removed, the root cut in pieces, with holes through them, and hung up to dry upon cords about the tents, or on the horns of sheep."

BRIDGEWATER TILES.—“*An Irish Subscriber*” will be obliged if “*A Somersetshire Parson*” will mention where the “*Bridgewater tiles*” (which he recommends in his article “*Wall Coping*”), are to be procured, and what is their cost; also if they could be obtained at any leading seaport town, and where.

EGYPTIAN ARUM.—“*F. B. B.*” wishes to know under what circumstances the Egyptian Arum attains its largest size in this country. In New Zealand, he adds, that it will, during the summer, from one plant become a mass 3 feet through. He likewise states that between Warwickshire and Worcestershire there are fields of Snowdrops. This is not uncommon where they have been long established.

RUNNER KIDNEY BEAN (*Lansdowne, Worcester*).—Our correspondent had a variety called “*Zebra*,” the seeds being light-coloured, striped with black, and the pods 10 inches long; he has lost his stock, and wishes to know where he can procure seed.

VINES (*An Irish Subscriber*).—Neither of the Vines you mention is suitable for a cylinder vine. Royal Ascut would do in a ground vine. The following are all adapted for cylinders:—*White*: Early White Malvasia, Pitunston White Cluster, Royal Muscadine, Stillward's Sweetwater Early Summer Frontignan, and Graham's Muscat Muscadine. *Black*: Black Prince, Black Hambargh, Purple Footainbleau, Espiran, Ingram's Prolific Muscat, Jura Frontignan.

DATES OF INTRODUCTION (*L. M. K.*).—We really cannot afford either time or space to detail the dates of introduction of twenty-five Conifers. If you refer to Loudon's “*Flortus Britanncus*,” you will find the dates mentioned.

FRUIT TREES ON NORTH WALL (*D. Shepherd's House*).—The Morello Cherry, and Thompson's and the Red Doyenne Pears, will ripen on your almost sunless wall.

TRAINING NAILS (*G. V., Devonshire*).—We do not know where Hill's Permanent Tie Nails can be procured. Eyed nails for training must be put in where and when they are required. There is no arbitrary distance.

EMPLOYMENT IN CHISWICK GARDEN (*A. B.*).—Write to Mr. Barron, Royal Horticultural Society's Garden, Chiswick, W.

SOWING SCOTCH FIR (*St. George*).—The seeds should be sown early in March in light sandy soil, and covered lightly with fine soil. You have, probably, covered the seeds too deeply, which may account for their not vegetating; but very likely they were not good. Try covering less deeply with soil.

PRUNING DWARF HYBRID PERPETUAL ROSES (*Agnes*).—“The advice to cut down your vigorous-growing Manetti-stocked Roses to 8 inches or 1 foot, is not good. You will only produce more vigorous growth and blindness. As your Roses bloomed well last year, and as you do not speak of blindness, thin-out the small wood, cut-in to a good eye the side wood, and cut the main branches, whether they were blind or not last year, to a good eye at their summits. My plants of *Acidalia*, which I have had sixteen years, are cut to about 6 feet. I am persuaded that it is a good plan to move and cut-back the roots of Manetti Roses annually or biennially. The plants like the stirring of the ground under them, and by root-pruning produce more flowers and less blind wood. The wood that from strong growth goes blind one year, if cut but little, will bloom abundantly in the next. Manetti-stocked Roses may be moved any time from September to February, or even later, with care. Take them up carefully, cut their roots to the general radius, and they will repay you for the trouble. In my fine sandy loam they strike vigorously on their own roots in one season, so that if I like I can cut the whole of the Manetti roots away. You say that ‘many articles on pruning Manetti-stocked Roses do not distinguish between standards and dwarfs.’ There are no such Roses, or there ought not to be, as standard and half-standard Manetti-stocked Roses. How could you bury the stock 2 inches over the point of union? I once was shown several Rose trees that never produced a flower, or only a very poor one. Some of them were 12 feet high. The Roses were dead, and all that was left was the Manetti. Close by was a half-standard Manetti-stocked Rose. It was a complete thickset of suckers. I could see no Rose wood at all; so I took out my pruning knife and cut away all the suckers, and in the centre were the remains of *Baronne Prevost* with a little foliage, by which I knew it, as there is no other Rose but *Triomphe d'Alencon*, which was not in existence at the time, that has the same foliage. Having cut off the suckers, I said in triumph, *The Baroness will flourish yet again*. The next year I went to see, and was not disappointed. However, standard and half-standard Manetti-stocked Roses would not flourish for any length of time unless the bark were kept scored and protected from scorching heat by some moist material.”—*W. F. RADCLIFFE.*”

ALLAMANDAS STARTING (*T. B.*).—For Allamandas to flower well at the end of May, they should at once be started. They should be fresh-potted if the roots are closely matted round the pots, but without disturbing them to any great extent, merely picking away any loose soil, and placing in a pot of the same size as before, or but little larger. If on turning the plants out of the pots you find the soil in good condition, you may merely rectify the drainage, remove the surface soil, and replace with fresh. The soil should be gradually brought into a moist state, and a moist brisk heat afforded. If pruning be necessary it ought to be done now.

GROWING FUCHSIAS FOR EXHIBITION (*Idem*).—Your newly-struck cuttings in thumb pots should be potted into 48's and kept slowly growing in a house, placing them near the glass, and where they can have air, for they must not be allowed to become drawn. When the pots are filled with roots, shift the plants into pots a size larger, and this must be done repeatedly, changing the pots as often as the roots reach the sides, and being careful never to let them want for water; at the same time they must not have too much. If the plants branch, or push side shoots near the bottom, the leader will not require stopping; but if there are no side shoots the point of the leader may be taken out when it has grown 9 inches, and one of the best of the shoots proceeding from the stopping trained in place of that removed. The side shoots for a foot upwards from the pot should not be stopped until they are 9 inches long, when their point may be taken out, and the side shoots higher up the stem may be stopped sooner and oftener, so as to secure pyramidal growth. The plants should be in their blooming pots not later than June, and the stopping may be practised to within six weeks of the exhibition; but it is well not to continue the stopping too long. All flower buds should be picked-off as they appear, or when a shoot shows flower take out its

point, but not later than six weeks before the show, for, as already stated, it is well to err in this respect, as the plants are more easily retarded than forwarded. They cannot be kept too cool and airy after May, for if drawn up by heat they grow too fast, and are long-jointed, with branches and blooms far apart. The plants should have a single upright stem, and be symmetrical in form, tapering upwards from a wide base, the shoots equally disposed on all sides, and well furnished from the rim of the pot upwards. The main constituent of the compost should be turf cut 2½ inches thick from an old pasture, where the soil is a good, yellow, not very strong loam, but strong rather than light, laid up for six months; or it may be used fresh if exposed to a strong heat to destroy the weeds and grass. Tear it in pieces with the hand, and use it rather rough. One-half of this, one-fourth old dry cow dung, and one-fourth leaf mould and charcoal in pieces, from the size of a hazel nut down to that of a pea, will grow Fuchsias well. Mix the whole well, and add sharp sand in proportion to the soil, so as to render it rather sandy. When the pots become filled with roots after the final potting, liquid manure may be applied two or three times a week. To have *Cherodendron Balfourii* in flower at the period you name, no time should be lost in starting it. Your other question shall be attended to.

AZALEAS DIFFERENTLY FLOWING (*An Old Subscriber*).—Some kinds of Azaleas have the peculiarity of producing different-coloured flowers on the same plant, but the variation is not generally permanent. We are unable to account for the peculiarity.

APPLES FOR A TRELLIS (*Turo*).—Your trellis will be very suitable for Apple trees, and we should plant double oblique trees, and, of course, train them obliquely. The trees should be planted 2 feet apart, and the length of trellis named will require eighteen trees, which should be on the Paradise stock. The following *dessert* sorts will suit:—*Dutch Magbonne*, *Margil*, *Sturmer Pippin*, *Scarlet Nonpareil*, *Adam's Pearmain*, and *Cedlin*. We would have three of each. If you wish for *kitchen* Apples, Cox's Pomona, Tower of Glammis, Manks Codlin, Keswick Codlin, Nonesuch, and New Hawthornden. You may plant with safety during this or next month, but the earlier the better. The trees may be procured of any of the principal nurseries. If you determine to have maiden plants, you may head them back and form double horizontal cordons.

POTATOES FOR CLAY SOIL (*E. F. W.*).—For first early:—*Rivers's Royal Ashleaf*; second early, *Milky White*; late, *Paterson's Victoria* or *Sherry Blue*.

GOOSEBERRY CATERPILLAR (*G. P.*).—During the present month remove the soil about the bushes to a depth of 3 or 4 inches, bury it in deep trenches at a distance from the bushes, and replace it with fresh soil or manure. Upon the appearance of the caterpillar the bushes should be dusted with belladonna powder, or they may be syringed and then dusted with lime, which should be put in the stems and scattered on the ground. Two inches thick of tan spread round the bushes and dug in or burnt in autumn, has been found a very efficient preventive.

PRUNING MOSS ROSES (*Idem*).—The Moss Roses layered or pegged down should be cut-in to two eyes, the weak shoots being cut-in to one, and any strong ones left with three.

BONE DUST FOR DESTROYING MOSS ON LAWN (*James B.*).—Bone dust from its promoting the growth of the grass is a good destroyer of moss; but we cannot say that it is the best. We recommend you to scratch the lawn well with an iron rake, and after removing as much of the moss as possible by that means, to give a good dressing of very rotten manure in March. Early in April rake it in, clear away all the loose manure, and then sow 4 lbs. *Festuca duriuscula*, 4 lbs. *Cynosurus cristatus*, 4 lbs. *Trifolium minus*, and 4 lbs. *Trifolium repens*, and if the lawn is shaded by trees, *Poa nemoralis*, 2 lbs. in mixture for an acre. Roll the surface well after sowing, but not again for a month, then mow and roll as usual. Bone dust may be applied at the rate of 8 cwt. per acre.

EVERGREENS FOR ROCKERY (*Idem*).—Nothing thrives so well as the *Asplenium japonica*. We would make it the principal shrub. Common Laurel, Yew, Holly, *Derberis aquifolium*, and *D. repens* will all succeed tolerably well, and *Rhododendron ponticum* would do in your soil. No time should be lost in planting them, as unless they be established before the Oaks are in leaf the ground will become so dry that the shrubs will perish of drought. Early autumn planting is best, but now is a good time.

VINE-GRAFTING (*A Subscriber*).—The scions should be inserted in moist soil or sand, in pots, and kept in the same house with the stock. The latter ought to be cut back at the winter pruning to the point at which it is to be grafted—that is, to a bud or eye opposite the place where the scion is to be put. When this bud has grown 6 inches pinch it back to two or three leaves, and whip-graft on the opposite side. Bind with a strip of matting, but not very tightly, and cover with clay, and then with moss over the clay, leaving the buds exposed, the moss being kept moist by frequently sprinkling with water at the same temperature as the air of the house. When the buds on the scion have expanded, one of the leaves on the stock may be removed, and when the scion is fairly in leaf the whole of the shoot on the stock may be removed. Your stock being thick we would proceed by side-grafting, which is only a modification of whip-grafting, putting the graft on the side of the cane and not beneath it, which is bad. If your stock is not now cut back do not do so, but let it push and then thin the shoots, leaving a few leaves opposite where the graft is put so to appropriate the sap, but remove or disbud entirely above the graft. When the union is complete you may cut the stock down to the graft, which should have a very encouragement to produce as much foliage as can be exposed to light.

LIQUID MANURE FOR EVAPORATION IN A FERNERY (*D. R.*).—We have tried it and we cannot say that it is injurious, but it certainly does no good, as the Ferns thrive quite as well when water only is employed. If the manure water is used strong some Ferns have their fronds discoloured by it. Charcoal is good for mixing with the soil, but small pieces of sandstone mixed with the soil keep it porous, and are quite as beneficial as charcoal, if not more so. The peat you name is not what we would recommend, but so far as we are aware it will not prove injurious.

LIQUID MANURE FOR GOOSEBERRIES (*Idem*).—Liquid manure would not injure Gooseberry bushes. It is best given when they are in growth. A thorough soaking given during any dry period that may occur after the bushes are in leaf will prove beneficial, and it may be continued up to the time that the fruit begins to ripen.

FLOWER GARDEN PLANTING (South Croydon).—Your plan is anything but a good one, there are so many points without meaning. We do not plant groups, but merely criticise. However, the following would look well:—Your central circle filled with Little David Pelargonium, with an edging of *Cineraria maritima*, or white-leaved *Centaurea*; then fill the little circle with *Aurea floribunda* *Calceolaria*, and the four pair of tailed small beds you may plant—first, next the little circle, with Purple King Verbena; second, with Christine Pelargonium; third, with dwarf *Ageratum* or bluish Verbena, like old Blue Bonnet; fourth, with Harry Hiever Pelargonium or Monitor Scarlet Pelargonium, or a low-growing Scarlet Verbena, as Lord Raglan. (A. H. W.).—We must not begin to plant beds, we must only help planters. However, the border No. 1, we would plant thus—*Cerastium*, blue Lobelia, *Aurea floribunda* *Calceolaria*, Mrs. Fielder, an improved Purple King Verbena; and back, Scarlet Pelargonium, moderately strong. The little beds we would plant with Verbenas, as more lasting than annuals.

PLANTING A CHURCHYARD (A. Z.).—It is almost impossible to give an outline of planting a churchyard in a smoky neighbourhood without definite plans or seeing the ground. In a very smoky place a row of Maples, Thorns, and Oriental Planes might be placed round the three-sided boundary, and by the sides of the walks, Mountain Ash and Poplars, the latter to have their roots cut if inclined to grow too large; or Weeping Willows might be substituted for them. If very smoky few evergreens except Aucubas and, perhaps, Box will live. If not very smoky, we would place Weeping Willows and common Yews round the boundary, and plant Cypress by the sides of some walks, and Irish Yews by others. If room can be spared in the centre, two or three groups of Arbor Vites and Red Cedars would also be in character.

REMOVING AND HEATING GREENHOUSES (South Croydon).—You had better make arrangements in writing with your landlord before you erect your greenhouses and frames on brick piers. In having no stovehole for your boiler, your hot-water pipes must not be below the level of the boiler. You may raise the pipes any reasonable height above the boiler, if it is a close one. To your question, then, of raising your pipes we reply, Yes; but your plan shows your pipes falling below the level of the boiler, and that will not do; neither does it answer well to take the pipes under such circumstances below a doorway, and raise them again to the general level on the other side. Even without sinking a stovehole the pipes might be so placed in the house as not to interfere with pathways or doorways. When several houses are to be heated from one boiler, a very simple plan is to have a flow and a return pipe at a low level all the length of the houses, and from these take pipes to heat each house separately; but in that case there must be a sunk stovehole.

HEATING BY STEAM (Subscriber).—We have little faith in heating houses, pits, and frames economically by pipes from a boiler heated by a gas ring beneath it. With such a small fire we fear that the steam would soon be condensed into water. Steam is economical when much is to be done from one good-sized furnace.

EMPLOYMENT IN A NURSERY (N. W.).—You cannot do better than write to the nurseryman as you propose.

HAY'S STOVE (T.).—We do not know where either it or the charcoal for it can now be obtained. There is a firm at Ebbwbury that could supply the charcoal, but it does not seem to care about doing so.

BOOKS (A. Ploughboy).—"The Cottage Gardeners' Dictionary," and Thompson's "Gardener's Assistant," will suit you.

REMOVING PHLOXES—SAWDUST AS A PLUNGING MATERIAL (Brown).—You may remove the Phloxes into good fresh soil with profit, and if the stools are large, divide them, but, of course, if you divide them much into small pieces, they will not bloom so well in summer as transplanting and moderate dividing would insure. When small tender plants are plunged in sawdust, the sawdust clings to the sides of the pot, and the bottom hole in the pot is so apt to be blocked up that the plant will suffer from want of drainage—how we know not, but we have had the sawdust insinuating itself until it became as hard and as firm as a cork. If sawdust is mixed—that is, old and new, from soft wood and hard wood, it is very liable to produce fungi and bad-smelling, quick-spreading Conserve. The fresher and the less mixed, therefore, the better. A heap from 24 to 30 inches in thickness by itself, will yield a mild lasting heat, but when large pots are set in it, it is advisable so to place the bottom of the pots that the sawdust do not reach the holes for drainage.

RIPENING BLACK HAMBURGH GRAPES AT CHRISTMAS (G. E.).—To have good Black Hamburg Grapes for sale or otherwise at Christmas and afterwards, we would advise a different treatment from that which you propose, since economy is your object. We would advise keeping the Vines as late as possible from starting, by ventilation and shade in bright weather, but after fairly starting we would let them have no check, but rather assist them, so as to have all fully ripe by the beginning of October. Grapes not ripe then will not ripen well afterwards, unless started very late, and that would involve the exercise of much skill. Grapes well ripened at the time specified will hang under fair treatment four or five months. The treatment they require is thinning the bunches a little more than usual, and keeping as much heat in the pipes in winter as will exclude frost, and, with ventilation, will secure a dryish atmosphere, as damp will be your chief enemy. It is in your favour that the Vines are planted inside, and the outside border should be protected with litter and means for throwing off the wet after the end of September. If you wished to have very late Grapes up to March, you will require such kinds as Lady Downe's Gros Guillaume, and Calabrian Raisin.

PAINTING A GREENHOUSE—PROPAGATING FRAMES (Mary).—Nothing answers better than white, or light stone colour for the inside of the roofs of houses, but it will be more pleasant to the eye if striped with blue. We have no objection to your having your stage pink, or any other colour that pleases you best, but most of us are content with stone colour because it shows the dirt less. Invisible green is sometimes used for the outside of houses, but white seems most lead in paint. Such little frames, 2 feet square, are most useful in propagating houses, and have been frequently recommended by Mr. Fish. He also advises that the top should be moveable, as that in the case of delicate seedlings guards against damp with little trouble, by merely reversing the glass and placing the under side uppermost. In raising seedlings, especially small ones, in a hotbed, provided the seeds are three-quarters of an inch from the rim of the pot, a square of glass laid over the pot answers remarkably well, and that may also be quickly turned. Of course, as soon as plants are growing freely, they need no glasses of any sort in a hotbed or

hothouse. Even when no such little frames are at hand, much can generally be done by keeping all tender plants by themselves, giving less air, and more dewing with the syringe and shading, than to established plants.

ERECTING A PINE PIT (Southerner).—The height of the walls of your proposed Pine pit must be regulated according to the mode of culture you decide upon—that is, whether you are to depend on fermenting material for bottom heat, or on hot water. The back wall of your pit is to be the front wall of a shed now existing, containing a boiler which heats other houses, and from that boiler the pipe passes through the ground intended for the pit, 3 feet beneath the surface. There need be no difficulty about the heating, therefore, as you can either keep your pipes in the pit at that level, or raise them to a higher level. To make the most of such a pit, all the space would be occupied, and there would be no paths in the house, and, therefore, all necessary work would have to be done by moving or holding up the sashes. Now, using hot water alone, we would have the back wall 7½ feet, and the front wall 5 feet high, which would make the back 4½ and the front 2½ feet above the ground level, provided you excavated the ground 3 feet or 3 feet 3 inches. At this depth we would have 3 inches of concrete; on that, 18 inches from back and front, we would have a 4-inch pipe going round the pit for bottom heat; between the pipes we would lay brickbats as open as possible, and cover 4 or 5 inches above the pipes, making the last covering of clean pebbly gravel. On that we would have a foot of plunging material, or 15 or 18 inches of soil in which to plant the Pines, keeping the tallest at the back and the lowest towards the front. Above the level of this plunging material we would have two pipes round the ends and front, and one along the back as a return. At back and front we would have three iron or earthenware pipes standing up above the plunging material for a couple of feet, the upper end furnished with a plug, and the lower end open among the rubble round the bottom-heat pipes, and by these we could let air and moisture into this rubble chamber at pleasure. If you mean to secure bottom heat by fermenting material, then your walls would have to be at least 2 feet more in height. Even with such a narrow pit or house as 8 feet we would be strongly tempted to have a passage either at back or front, which would permit of work being done without opening the sashes. To your specific inquiries, then, we would say, that we see no difficulty in heating, whatever the plan adopted—of course, the return must communicate with the bottom of the boiler, or with the return pipe already in work—that one pipe round the pit will not be nearly enough for a pinery, but the height of the pipes is of no consequence provided those intended for top heat have a free exposure to the atmosphere of the pit to be heated; that the size of the sashes, 3½ feet wide, will do well enough; and that the walls should be 9 inches thick. We are much obliged to you for the seeds of the Spanish Melon, and as you speak of it so highly we will endeavour to give it a fair trial. Unless the varieties are very good, we always decline trying batches of Melon seed, as to do them justice much room is required. We once grew forty kinds, all with high characters, and as we had little room we gave each a large pot in a very light house, and though we had fine healthy fruit, there was not one we would have cared to grow again.

PROPAGATING PROLIFEROUS FERNS (An Old Subscriber).—When the plants proceed from the ends of the fronds they may be left on until they are of a size fit for potting, and may then be removed and potted; or they may be established in pots whilst on the parent frond by placing them on soil in a small pot, and securing them with a peg. The plants being situated on the surface of the fronds, they may be left until they fall off, or when of good size and the old frond becomes mature, it may be laid on a pot or pan filled with soil and pegged down by the midrib, a little sand being scattered over the frond so as to partially bury it, and if kept moist the young plants will soon root, especially if covered with a bell-glass. The young plants proceeding from the stipes near the crown of the plant should be left on the old plant until they are of a size fit for potting, when they may be removed and potted-off. In most instances the young plants will have emitted roots by the time the old frond is mature, and that will be the proper time to remove them. They should be potted into sandy compost, and not in sand only. Two-thirds fibrous peat or old cocoa-nut refuse, and one-third sand, will be better than all sand.

PROPAGATING VIOLA CORNUTA AND VIOLA LUTEA (Lincoln).—The old plants of *Viola cornuta* may be taken up this month, divided, and planted as you propose. If the weather at and after planting prove dry the plants should be watered, and a slight shade be given from bright sun until established. Seeds of *Viola lutea* sown now in pans and placed in a gentle heat afford fine plants for autumn bloom; but they do not bloom so freely as older plants. The seedlings should be kept near the glass, be pricked-off when large enough, grown on in heat, and well hardened-off previous to planting out. They will bloom in August, earlier or later, according to their forwardness.

TURF SOIL (A Subscriber).—Your soil or turf will answer for potting Camellias. The limy matters, we presume, form only a small proportion of the whole, and in that case will not prove injurious. Your soil from the turf will be too light for the culture of Pear, Apple, and Peach trees; but it will answer for a compost for Apricot and Plum trees if enriched with one-fourth cow or sheep droppings. It will do for a Vine border, but we should have liked it better had the sand been sharper or more gritty.

FORWARDING SEEDLING ZONAL PELARGONIUMS (Devon).—Your seedlings should be kept near the glass, and have a fair amount of air, avoiding cold draughts, otherwise they will become drawn. When large enough to handle they should be potted-off singly in small pots, be placed in a gentle heat, and be kept rather close, moist, and shaded from bright sun until they recover from the potting, when they should have a position near the glass, and an abundance of air on all favourable opportunities. The plants, having made two or three leaves in addition, should have the growing point removed with the point of a knife, and should be shifted into pots a size larger whenever the pots become filled with roots, and this may be continued until the plants are in 6-inch pots, which will be quite large enough for you to test their blooming qualities the first year. When the plants are in free growth they should have a light and airy situation in a cool house, where they will do much better and flower more in character than in a heated structure, which is not suitable for them after they become established in pots.

SOWING BUCKWHEAT (Belfast).—Buckwheat should be sown early in April; but if the weather is favourable it may be sown in March, the

ground being in good working order. Three bushels are the usual allowance per acre; but the ground being occupied with trees, half the quantity will be sufficient seed per acre.

TEMPERATURE FOR PELARGONIUM CUTTINGS (*Idem*).—The temperature may be from 60° to 65° at night, and from 70° to 75° by day, the atmosphere being kept close, moist, and shaded from sun. The cuttings will succeed in a lower temperature, but their rooting is not so speedy.

PROTECTING PYRAMID FRUIT TREES (*Catalpa*).—The best plan that we know is to put in some stakes around the trees, and so far distant from them and so high as to keep the material put over them from rubbing against the blossoms. The stakes may be driven into the ground, and securely tied together at the top. Over these may be put a covering of tiffany, so as to protect the trees. It should fit closely at top and all round; but it will not matter if the material do not reach lower down than a foot from the ground. The covering should be secured to the stakes at bottom with string to prevent its being blown off or brushing against the blossoms when strong winds occur. The covering should only be used on frosty nights, or during the day when there is frost; at

other times the trees should be exposed. It will not matter about the trees being covered, so long as the bloom is not expanded, then the covering may remain on by day, which will tend to retard the blooming, and lessen the danger of injury from frost.

TEA-SCENTED ROSES (*W. Booth*).—The best are Adam, Devonien-sis, Madame Villermoz, Souvenir d'un Ami, Souvenir d'Elise, Bouton d'Or, Madame Margottin, Elise Sauvage, Vicomtesse de Cazes, and Rubens.

LATE VINES FOR GREENHOUSE (*Idem*).—Black Prince, Black Hamburgh, and Black Muscat of Alexandria.

PANSIES (*Homunculus*).—Of the growers you name, Mr. Bragg lives at Slough, Bucks, and Mr. Dean, at Shipley, York-shire. We do not know the "Red Russian Potato."

NAMES OF PLANTS (*T. E.*).—1, *Lomaria spicant*; 2, *A Myrtle* of some kind, no flowers; 3, *Chimonanthus fragrans*; 4, *Aspidium falcatum*; 5, We will give the name next week; 6, *Selaginella cesia*. (*Tertia*).—1, *Adiantum cuneatum*; 2, *Adiantum athiopium*; 3, *Nephrolepis cordifolia*; 4, *Pteris longifolia*; 5, *Selaginella Brannii*; 6, Too young. (*C. G.*).—1, *Deutzia gracilis* *floro-pleno*; 2, *Myrsiphyllum asparagoides*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending March 3rd.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE HEWITT TESTIMONIAL.

THE subscription list for the above object has now been open for five months. I am anxious to give every one an opportunity of sending his subscription, and therefore wish to give notice to any of my brother fanciers or committees of shows who have not yet sent in their names, that the list will be positively closed at the end of the present month (March), and I hope before that time they will make up their minds, and let us have the list completed by the addition of their names.

I cannot allow this opportunity to pass without tendering to those ladies and gentlemen who have so promptly and liberally responded to the proposal I made six months ago, my sincere and hearty thanks for their kindness and generosity; and I am sure they will join with me in hoping that Mr. Hewitt may long be spared to officiate as a judge at our poultry shows.—J. R. JESSOP, *Beverley Road, Hull*.

CLASSES OF BRAHMA POOTRAS.

UNCLE SAM and Cora, whose portraits figured in the "Poultry-yard," had much more grey in their plumage than there is in many Light Brahmas at our shows, and they, to my mind, were quite beautiful, the *beau idéal* of Brahmas. Some Brahma-fanciers will disagree with me when I state my conviction, as regards breeding Brahmas, that we make a great mistake in dividing them into Dark and Light, and that the right shade should be a clear grey speckle on a white ground, removed alike from heavy dark and white. This was the shade which the United States fanciers advocated when they first sent these excellent fowls to England, and the advice sent over with the importations commencing in 1853 or so (which disseminated over England the hardest, and perhaps the best fowl we have), was to guard against a tendency to too dark or too light a shade, and to preserve the sharp grey marking on a clear white ground by mating light with dark and dark with light. The division of Light and Dark has been easily obtained by mating dark with dark, and light with light. It is a mistake to think that all Dark Brahmas have been obtained by means of a cross with Dorkings, although some Brahma families I know are so derived. Light Brahmas, also, sometimes show unmistakable signs of crossing with white Cochins; but I know for a certainty that pure Brahmas may be bred of all shades from quite dark to quite light.

I have bred my Brahmas divided into Dark and Light, because I like to make the sale of my surplus chickens pay the

cost of my amusement, and purchasers most frequently ask for Dark or Light, otherwise I should have aimed exclusively at a sharp grey marking on a clear white ground, producing a bright grey fowl. For many years I have divided the Dark and Light, and kept them distinct.

My Dark are of so dark a grey as to be almost black in the marking; the marking is in different specimens fine and mossy, or of a bolder character; the ground colour, little seen, is clear white; and the bottom colour deep grey.

The Light are white on the surface only, with well-defined black in the hackle, tail, wing-feathers, and a clear, full grey as the bottom colour. The grey is so full that a feather cannot be ruffled, or a breath of wind blow over the fowl without showing it. Like Mr. Pares, I think white under fluff a great fault.

I have said that I consider it a mistake to divide Brahmas into Light and Dark; if there must be division of colours, there should be three classes instead of two. The grand characteristics of the Brahma are, however, of much greater importance than colour—their hardiness and strength of constitution, their tame domestic habits, their care of their own health, scarcely surpassed in sense by the dog, and their excellence as layers and as table fowls. The full wide shape, compact make, shortness of leg, peculiar expression of eye, prominent brow, and the unique form of the pea-comb, unite to make them distinct from all other fowls.—E. WATTS.

I AM a breeder of both Light and Dark Brahmas, and quite agree with Mr. Pares' and Mr. Worthington's remarks that separate prizes should be given to Light and Dark Brahmas, as I am sure the Light stand no chance when shown in the same class as the Dark. At the late Cambridge Show I thought it useless sending Light Brahmas, although I have the fowl that won the cup at Birmingham, and the highly commended hens, so I sent a much inferior pen of Dark.

I would suggest that committees of shows, if they cannot give a cup to the Light as well as the Dark, should not give one to either, but give money, equally divided between the two.

As the Light Brahmas are greatly on the increase, I think it quite time they should be placed equally with the Dark at shows.—HERBERT DOWSETT, *Park Farm, Pleshey, near Chelmsford*.

I AM very pleased to see others have taken up the Light and Dark Brahma question; but I must say I think "Y. B. A. Z.," although he has "no unkind feeling towards his old love," is rather hard on her, and runs the Light Brahmas down too much. He says the Dark beat them in every point. Now, are not Light Brahmas quite equal to Dark in all points but size, and many in that?

Last season I bred several Light Brahma pullets, which at

six months old weighed 6 to 7 lbs., and cockerels at the same age 9 lbs. I have now a Light Brahma cock hatched in 1866, the one that took the second prize at Southampton in November last, which weighs 12 lbs., and a hen of 1866 of 9 lbs. weight. Nearly all my birds are well leg-feathered (a number of the Dark which are exhibited are vulture-hocked). Also, in respect to the comb, which is one of the most marked characters of the Brahmas, are not the Light often superior to the Dark? I am aware many of the Light have the centre comb too much twisted; but how often do the Dark have very thick clumsy combs; in fact, almost a strawberry comb.

As "Y. B. A. Z." says, the colour of the Light Brahmas is now perfect in many birds, and no doubt, as Mr. Crook states, they will now soon surpass the Dark in size, if they only have fair treatment, and exhibitors see that it is so.

"Y. B. A. Z." says many shows could not afford two cups in the Brahma class, and that many committees find it hard to make both ends meet, even with such a liberal prize list as that of the Bristol and Clifton Show. Would it not have been much to the advantage of that Show to have had more cups of less value instead of one of £12 12s. and eight of £7 7s.? The same amount of money would have almost procured fourteen £5 5s. cups, which, surely, are quite valuable enough for prizes, as the honour and not the value is what is desired by exhibitors.

Let me ask, in conclusion, whether people are ashamed of their names, that so many avoid letting them appear. It is a great misfortune we should not know the names of the writers of articles in "our Journal," so that we might form some idea of the value of the hints and suggestions thrown out. Doubtless most of our readers do know who the great guns, such as "Y. B. A. Z.," "WILTSHIRE RECTOR," "NEMO," "NEW-MARKET," &c., are; but there are many of our smaller guns whose remarks would be far more interesting and valuable if the name and address were appended, instead of some hieroglyphics for which no one is the wiser.—PHILIP CROWLEY, *Culverton House, Alton.*

RAILWAY CHARGES.

In the Journal of February 27th appeared an article by "BRAHMA" upon the excessive railway charges for carriage of fowls for exhibition. As one of the Honorary Secretaries of the Somerset County Poultry Association, I distinctly deny the truthfulness of that portion of the article which has reference to a charge of 5s. 3d. being made from our Show to the railway station.

Various exhibitors having requested that their railway charges for through-carriage should be paid by the Association, and recharged to them, such course was adopted by our Committee; and I find from the accurate mode in which the arrangement with the Association in respect to through-carriage for hampers, &c., has been kept by the Bristol and Exeter Railway Company, that one charge only of the exact sum of 5s. 3d. for through-carriage has been paid, opposite which sum is the number of the label and name of the exhibitor.—ONE OF THE HON. SECRETARIES.

MANAGEMENT OF BRAHMA POOTRAS.

FROM nearly all who had eggs for hatching from me last season I had glowing accounts of the pullets. In a note from an old friend at Richmond (Mr. Kinghorn), he says, "Your giants are great favourites, and lay every day. Another says, "Dr. Curtis has seen the pullets from your Dark Brahmas, and he says they are worth £1 per head."

Our mode of feeding does not differ from that pursued by other people, with the exception of breaking up all bones. I have a raised block for the purpose, and with a common hatchet break, or rather smash, up every morsel of bone, whether it be of fish, flesh, or fowl. It would please any one to see how soon the fowls put in an appearance when the chopper goes to work. I have a beautiful grass run for them, but very indifferent shelter for them in cold or wet weather. The old fowl, of which I sent you a notice as having laid 279 eggs, made the number up to 289! Now I am happy to say she is having a thorough shift, and still looks as rosy about the head as any of the pullets.—J. P.

BIRMINGHAM POULTRY SHOW.—We are informed that the Council of the Birmingham Cattle and Poultry Show will meet shortly to revise the prize lists for the present year. Intending donors of special prizes, or exhibitors having suggestions to

make as to changes desirable, will do well to communicate at once with the Secretary.

FOUR-TOED HOUDANS.

I AM glad to see that several of the leading breeders of Houdans have taken up the cause of the fifth toe, which appears to be so strong an abomination in the eyes of Mr. Schröder and others. It is one of the leading characteristics of the breed, and, in my opinion, is as important as crest, beard, or plumage. Besides, so strongly has this "abominable" point been insisted upon, that myself and other breeders have abstained from using birds which do not possess it; and our efforts have been so far successful, that out of nearly one hundred birds bred by me last year, I had but three with only four toes, and these I consigned to the cook.

If Mr. Schröder's suggestions were adopted, the care we have taken in improving our stock will have been entirely thrown away, and we shall have to start afresh. This, I maintain, would be excessively unfair.

I have never had a Houdan with a bumble foot, so the fifth toe is not attended with those evil consequences which attach to the Dorkings.

"NEMO" says the plumage of Houdans has not yet become uniform. Let us make it so. For my own part I have a strong objection to Light birds, which become less distinctly marked with age, and have this year determined to breed solely from Dark birds, which are decidedly the most fashionable.—LINDUM.

A CAUTION TO FOWL-SELLERS.

THERE have been so many "cautions" in your valuable paper, and to which my attention has often been drawn, that I am surprised any one should be victimised after reading them. In spite of myself, however, I have to confess that I have been "done," and that, too, by a celebrated breeder and exhibitor of Buff Cochins.

The story of my wrongs, how my best birds were got before being paid for, and sent to an early exhibition, where they took cup and prize; how the gentleman wrote me stating that he had only taken second prize; next, how a week or two afterwards he stated that he could not pay me, as the secretary of said show had not paid him; and how after many months, and many instalments, I was completely "dropt," being minus several shillings, which the said gent deducted for part railway expenses when he came, several months before, to see my celebrated Buffs—a full account of this most interesting transaction I purpose sending to your Journal next week, if you will promise me a little space; and I wish distinctly and emphatically to state, that I shall do this solely to benefit those who may have to part with their "pets" from unforeseen circumstances, and as a "stopper" to those would-be respectable exhibitors.

If you can afford space next week for a letter from me, on this subject, I would esteem it a favour.—F. W., 14, *Westbar Green, Sheffield.*

[We hope this will suffice without further exposure. If the party you allude to does not fully satisfy you, let us know.—EDS.]

PIGEONS—NUMBER OF CROSSES.

I AM asked by Mr. Rose what number of crosses between two birds I consider are required in order to produce "fine healthy Pouters." If I understand the question rightly, the desired healthy Pouters may be produced from one pair of birds either having no relation to each other, or being distantly related. I am no advocate for a continued crossing, and think we often err in this, as we cannot be always sure of the origin of newly-acquired birds. If we obtain a good "strain" we should be careful of the cross we introduce, both as regards colour and style. Any strain may be kept up by matching relations now and then, and it is remarkable how far we may go in this way, without injuring the form or constitution of the birds.

About twelve years ago, during my absence from home, a pair of Pouters, mother and son, mated and produced a pair of eggs. The young birds were reared by a pair of Fantails, and finer healthy birds I never saw. I shall say nothing of their colour, but for size and perfection of shape I have not seen them surpassed. The descendants of this produce figure to this day in the high places of our best exhibitions. Such a

match as this no one would recommend, but two or three pairs of fine birds of one colour, or colours kindred to each other, will serve for many years without introducing any new blood.—JAMES HUIE.

ROUP IN PIGEONS.

The following recipe for roup in Pigeons may perhaps be of use to Mr. Boyd and other breeders. I have cured some most inveterate cases with it, and, proper time being allowed, do not think I ever remember it to have failed.

Upon a small handful each of rue, wormwood, and horehound, pour a quart of boiling water, strain off when cold into a common wine bottle, adding a small quantity of saffron and a little sugar, a table-spoonful to be given to the bird through a funnel every morning.

The mixture will keep good any reasonable time when bottled. I have also found it of great use, with other remedies, for cancer.—W. K. ROSE.

A GUIDE TO CANARY BREEDING.—No. 1.

AMONG our household pets, the Canary very deservedly holds a high place in our estimation. He is a cheerful, merry little fellow, and is at home alike in the cottage and the mansion, repaying such trifling attentions as he demands at our hands with the most delicious melody, which under proper training can be made to rival the notes of the sweetest song birds of Britain.

But not in this respect alone does interest attach to the Canary. An almost endless diversity of shape and plumage has rendered it a most attractive subject for the fancier; and the magnificent collections which are annually congregated at our great exhibitions at the Crystal Palace, Sunderland, Southampton, and other towns sufficiently attest the increasing interest with which this bird is regarded, while the large prices realised by good specimens indicate financial results of a flattering character. The impetus which the exhibitions have given to Canary-breeding is something extraordinary; and since it is an occupation, the tendencies of which are all elevating, and which can be carried on in the nursery, the parlour, the study, the conservatory, or indeed almost anywhere and everywhere, it shall be my object to give a few practical hints for the guidance of those beginners who may be disposed to "put up" a pair or two of birds for the approaching season. I do not propose to issue a learned treatise, but simply what it pretends to be, an A B C guide to those who are studying the alphabet of Canary-breeding.

All Canaries are, as a rule, divided into two classes as regards colour—viz, Yellow and Buff, or more technically speaking, Jonque and Mealy. Whether Norwich, Belgian, Cinnamon, Lizard, Green, or any other class, these two are the primary colours, any markings or variegations being built upon these two foundations.

It may appear strange to a novice when he hears that a Green may be a Yellow Green or a Buff Green, but a very little explanation will make this clear. Perhaps it will be better first to give a definition of what is meant by Buff, which has some very strongly marked features, while Yellow is conspicuous by their absence.

Buff or Mealy, then, in a Canary, is that dead, flat colour which is always found overlaid, more or less, by a white, silvery, mealy exterior, giving the bird the appearance of having been dusted with flour, sometimes almost to whiteness, hence the term mealy—and which flatness of hue with its overcoat of meal is clearly observable over any colour whatever. Yellow consists in the absence of this dead colour and meal, and the substitution of a clear transparent hue.

Jonque and Mealy are, in their application, more expressive terms than Yellow and Buff, and may, without too closely considering their etymology, be understood to convey the idea of a clear, glossy, brilliant, transparent shade of any colour, or a dead, flat shade of the same, overlaid by a coat of meal, which, since it turns Yellow to Buff, has occasioned the general use of these familiar words. We can therefore have, for example, "Jonque Cinnamon"—i.e., a pure, clear, brilliant, transparent cinnamon, and we can also have a "Mealy Cinnamon"—i.e., the same colour, but overlaid with more or less meal, giving it a subdued shade, which is to the other as Buff is to Yellow. The same observation applies to Lizards, and as stated at the outset, to all classes. It may not be so obvious in one as in another, but the distinction is there, and a very little experience will enable the beginner to detect it.

A right appreciation of the purity or depth of shade in colour

is arrived at only by experience, but this general explanation is given to enable the breeder to pair his birds properly, the first fundamental maxim being, Pair Jonque cocks with Mealy hens, and *vice versa*.

The Mealy birds of either sex are invariably the most compact in plumage, and the crossing of the colours induces this most invaluable property while it intensifies the colour *under the meal*, producing in some instances birds of a marvellous hue. The produce of two Jonques, even if high in colour, will be apt to be wanting in quality and what is called "open-feathered," while that of two Mealy birds will be deficient in colour. There are cases in which it may be highly judicious to pair two Jonques or two Mealy birds, and such is often done with a view to bring about certain desired results, but the beginner need not try any experiments. It is usual also in pairing crested birds to cross a crest with a baldpate. Two crests are seldom paired together unless for special purposes, though this also is sometimes done when special results are aimed at.

The birds should not be "put up" too soon. The state of the weather to a greater or less extent alters the time. They will breed under favourable circumstances at Christmas, but this is by no means desirable. Some breeders have favourite dates at which to commence; one of our most eminent breeders told me at the late Crystal Palace Show, that he is never later than the first week in March. Much, however, must depend upon the situation, aspect, &c. As a rule, the beginning of April is early enough to make a start, at least in the north. Remember that two fine days do not make a summer, and many a breeder has had cause to regret being tempted to pair his birds too early. Better begin late, very late, than too early—rely upon it nothing is gained by being impatient, and nothing is lost by waiting, till—when? Why till the nights are warm and your hens can see to feed at five o'clock in the morning.—W. A. BLAKSTON.

ADDING LIGURIAN QUEENS.

IN substituting one queen for another, inexperienced apiarists would do well to attend to all those precautions which have been recommended to be observed by Mr. Woodbury. A queen cage is a most useful auxiliary in the process, and the American plan of immersing the queen in liquid honey immediately before introducing her to her new subjects, is often crowned with success; but I have never in my own apiary used any of these adjuncts, my practice being based on the conviction, arising from experience, that bees will cheerfully accept any sovereign after they have fairly ascertained the loss of their own, provided that no encasements have recently taken place within their hive, and no stranger element has entered it.

During the breeding season the loss of a queen is generally discovered within twenty-four hours, and when the bees become conscious of their loss they are thrown into a state of agitation, and may be seen running out and in at the entrance, and up and down the front of the hive. If about two hours after this agitation is observed a new queen be given to them, they will receive her favourably, even though the hive should be filled with eggs and brood.

After breeding is suspended, and the bees have entered into a state of comparative repose, they might not, in the absence of a thorough disturbance, find out their loss for several days. When, therefore, I abstract a queen for the purpose of replacing her by another, I take care to rouse the hive into complete activity. If the queen is taken away in the morning I put the deprived bees into a state of general commotion in the after part of the day, either by tapping, partial driving, or elevating the frames and shaking the bees back into the box, according to the character of the hive operated on. This makes the bees search for their queen, and by the following day the unwelcome truth has been sufficiently learned that she is no longer among them. The signs which indicate this are as follow:—On removing the crown board, or turning up the hive if a common straw one, and blowing a little smoke on the bees, a continuous hum is set up by a general vibration of the wings, and a running-over the combs as if in search of something. The new queen may be introduced as soon as convenient after this evidence has been obtained, and I always inaugurate the introduction by a few whiffs from a fumigator held in the mouth.

In following the practice described, I do not remember ever having lost a queen, or requiring a longer interval than twenty-four hours between removing the old sovereign and substituting the new.

Hives in which queens have been imprisoned should be

allowed to remain in a queenless state for a few days before giving them a new sovereign; and I need scarcely add, that all operations should be conducted at a time when bees in neighbouring colonies are least likely to be attracted to the scene. Excepting during the swarming season, a more favourable reception is given by bees to fertile than to virgin queens.—R. S.

WHO FIRST SUCCEEDED IN INTRODUCING THE LIGURIAN BEE?

MAJOR MUNN, the inventor and patentee of "Munn's patent bar-and-frame hive, or miniature apiary" has recently read a paper before the East Kent Natural History Society, in which he makes such remarkable statements regarding the first introduction of the Ligurian bee into England, and other matters in which I am personally concerned, that I have been induced to correct them in a letter addressed to a local paper, in which appeared a report of his observations, and which letter I shall be glad to have republished in "our Journal." The true facts of the case were very well known to the apian world at the time, but it is not impossible that after the lapse of between eight and nine years, many may be imposed upon by the attempt now being made to claim on behalf of Mr. Neighbour credit for what was really achieved by—A DEVONSHIRE BEE-KEEPER.

"To the Editor of the *Dorset Chronicle*."

"SIR,—I am indebted to the kindness of a friend for the opportunity of perusing a copy of your Journal of the 22nd inst., which contains a report of a paper on "Bees," read by Major Munn before the East Kent Natural History Society, and in which I find it vouched for that "Mr. G. Neighbour, of Regent Street, was the original introducer of the Ligurian or Alp Bee, through a German named Hermann. Now, as I have always considered, and never before knew it disputed, that I was the first who succeeded in introducing this bee into England, I will briefly state the circumstances of the case:—

"During the summer of 1859, I entered into correspondence with M. Hermann, and received a queen direct from him at the same time that he sent some queens to Mr. Neighbour, one of which I believe found its way to the Rev. Mr. Scott, of Shepherdswell, in your neighbourhood, and I afterwards had other queens direct from him during the autumn of the same year. It so happened that all my queens lived through the following winter, whilst the others (Mr. Neighbour's and the Rev. Mr. Scott's) died, and the supply being cut off by the disappearance of M. Hermann, Mr. Neighbour possessed no Ligurians whatever, except what came from my apiary, until four or five years afterwards, when he succeeded in again obtaining bees from Switzerland. During the International Exhibition of 1862, Mr. Neighbour showed a stock of Ligurians, which I lent him for the occasion, and which he returned to my apiary when the Exhibition closed. From this stock, which he thus exhibited, he took orders from the Victoria Acclimatisation Society, for several stocks to be sent to Australia. These orders were in due course transmitted to and executed by me; the devices by which the bees were enabled to survive an uninterrupted confinement of seventy-nine days being contrived and executed by myself alone. To me, therefore, and to me alone, belongs also whatever credit may be due for the successful transmission of the Ligurian bee to the Antipodes, where it has since multiplied and flourished so abundantly.

"Major Munn also states that I now supply 'Ligurian bees and bee hives at £5 and £6 each stock,'—my price really being but £4 1s., including first-class frame hive, and taking upon myself the risk of transit to all parts of the United Kingdom of Great Britain and Ireland.

"I may perhaps be permitted to say a few words on the subject of hives. I have never sought to derive one penny advantage from the sale of those called after my name, but have always freely supplied patterns to be copied, without fee or reward, by any hive-maker who might ask for them. As regards price, a first-rate frame hive can be made and sold by the retailer at a fair profit for a guinea, and if dealers will not supply them at that rate I will do so myself, to any who may apply to me.—Yours, &c.—T. W. WOODBURY, Mount Radford Rectory, 26th Feb., 1868."

DISASTROUS EFFECTS OF FOUL BROOD.

I REGRET to find it stated in Major Munn's paper on "Bees," read before the East Kent Natural History Society, and to which I have already referred, that "Mr. Neighbour has to deplore the great loss of some sixty stocks of bees;" so that it would appear that foul brood has been just as disastrous in its ultimate effects on Messrs. Neighbours' own apiary as on those of their customers who have received bees from them since they undertook themselves to import and supply Ligurian stocks.—A DEVONSHIRE BEE-KEEPER.

EARLY QUEEN WASP.—A fine queen wasp was found on the lawn, near Hull, to-day (February 24th), and destroyed. Is not this very early? [Yes.]

OUR LETTER BOX.

DOUBLE-YOLKED EGGS (C. M.).—If two yolks are equally developed in the ovary, and pass at the same time into the egg passage, they become surrounded by the same white and shell. We never know a double-yolked egg produce a live chick.

COCK'S SOJOURN WITH HENS (Susan).—A fortnight if possible, but a few days are always considered sufficient. We consider three days enough.

STARLING PIGEONS—PINIONED DUCKS (Widgeon).—The Starling Pigeon should not have mottled shoulders. A pair of wild Ducks would not be disqualified because they were pinioned.

JUNGLE FOWL (*Idem*).—We have kept the "Gallus Bankiva" through many winters. We kept the birds at liberty, and in all weathers they roosted on the top of an unusually high holly tree. We do not believe they would do well with Golden and Silver Pheasants. We could never tame them. We endeavoured to keep the last we had in a large aviary, but he flew up against the top covering till he killed himself.

KEEPING EGGS (G. H.).—Take a deep bread-pan; at the bottom put wetted lime 3 inches deep. It should be so slaked that the egg put in it will retain the position in which it is placed. Stand the eggs in it closely together, small ends downwards. When the layer is full pour on sufficient slaked lime to cover every egg, add to it till there is enough to make every egg stand upright; when it is completed pour over again, and begin the third layer. Continue in like manner till the pan is full. They will keep as long as you please to keep them. If they are new-laid when put in they will keep so, but if they are stale they will not be restored by it.

MOPING PULLET (Lemon Buff).—Your Cochins pullet has not had the roup. They are not subject to it. She is in a bad state of body, and this inclines her to raw meat. Grass is good food. We recommend purging with castor oil till no more slime comes away, and feeding on stale bread and ale to keep up strength. We also advise a pill of campher the size of a pea every night.

DORKING HEN WITH INFLATED AUBOMEN (W. B.).—It is possible there is an obstruction of the egg passage. If it is caused by a broken egg, it is incurable; if by a whole egg, you will relieve it by taking a wing feather, soaking it thoroughly in oil, and passing it gently up the passage till it meets the obstruction. This should be done several times, and the feather should be dipped in the oil each time. This must be delicately done, as the egg breaks easily while in the hen, and there is no remedy in such a case. If it be so, the egg can be easily felt. If it is not, we know no remedy but active purging with castor oil to remove the cause of distress.

SWOLLEN CROP (F. S.).—The swollen crop in the Silver-Grey Dorking pullets probably arises from sluggish action in that organ. Give each a dessert-spoonful of brandy two or more mornings following.

BEARING DOWN IN A BRAHMA PULLET (Subscriber).—Citrate of iron will only do harm in her case. Your hen has a difficulty in laying. A feather soaked in oil and passed up the passage will enable her to lay without pain or effort. This will only be necessary two or three times. Let her have plenty of grass, and if you have lettuces give her some. It is not an uncommon case at this time of year.

GAME FOWLS, WITH GAME BANTAMS (W. H. B.).—It is not safe to let them run together.

GROUND OATS may be obtained from J. & B. Marsh, Corn Merchants and Steam Millers, Kingston, Surrey.

HEAT IN INCUBATOR (A. W. Shaw).—The temperature under the flannel is that which you must attend to.

BULLFINCHES (—).—Bullfinches are late birds at nesting. Give them the usual food—viz., rape, canary, and a small quantity of hemp seed not bruised. Place in the cage the material for building, let them have all the sun you can, and about the end of May probably they may breed.

MR. WOODBURY'S PHOTOGRAPH (C. A. J.).—You can have a photograph of Mr. Woodbury if you enclose thirteen postage stamps with your address.

BEE HOUSE—REMOVING BEES (H. A. F.).—We prefer a verandah or a lean-to shed, built against a wall, of sufficient width and height to shelter the hives, and permit all operations to be conducted at the back. Your question as to where to get a stock of Ligurians was answered by Mr. Woodbury in page 176. The best time for transporting a stock to Scotland is as soon as the dangers of winter are entirely over, and the bees are restored to full strength and activity—say April, or even May, according to the season.

BROWN SUBSTANCE ON THE ENTRANCE AND TOP OF A HIVE (E. Y. C.).—The thick brown composition which you describe is the excrement of the bee, and its appearance about the entrance of the hive may be regarded as the premonitory symptom of incipient dysentery, which, however, will probably disappear under the genial influence of a little mild and open weather.

BEE HIVES (J. D., Sheffield).—All depends upon the extent of your apian requirements. The scientific bee-keeper will find the Woodbury frame hive the best and the most profitable, whilst the novice and those possessed of but little scientific knowledge will do well to commence with flat-topped straw hives, such as the one delineated in page 178; or Payne's Improved Cottage Hive, described in "Bee-Keeping for the Many." Either of these can be manufactured by any ordinary straw-hive maker at a moderate price.

DRIVING BEES (A Bee-keeper).—If the bees of a strong stock are driven into an empty hive they will, if placed on their old stance, usually remain there and set vigorously to work after the manner of a natural swarm; and if a swarm of Ligurians are inducted into their well-stored dwelling they will thereby obtain a very great advantage and, doubtless, flourish amazingly, whilst no permanent stain will result to their purity. The few bees ordinarily sent with an Italian queen are, however, not sufficient to establish a stock in this way, or in any other than the ordinary manner—i.e., by putting the queen at the head of a stock of common bees.

RETRIEVER PUPPY DISEASE (S. H. Ridge).—The symptoms are those of "the distemper," in a very advanced stage. Give a grain of calomel and a grain of tartar emetic mixed. This will act as an emetic and purgative, but you had better read what Youatt directs in his work on "The Dog." It fills several pages.

From observations taken near London during the last forty-one years, the average day temperature of the week is 50.7°; and its night temperature 33.5°. The greatest heat was 67°, on the 12th, 1841, and 15th, 1828; and the lowest cold 17°, on the 17th, 1846. The greatest fall of rain was 0.70 inch.

PROPAGATION OF CENTAUREA CANDIDISSIMA.

N answer to your correspondent "J. A." (page 164), I am able to state that we have had good success here in the propagation of the above-named plant during September last. I consider September a desirable month for performing the operation. At that time the plants are well ripened, and the cuttings firm, without which there is but little chance of success.

Our mode of treatment is to make a common hotbed of dung and leaves, with 9 inches of sawdust on the top.

We are much in favour of the sawdust as a plunging material for many purposes. It is a very slow conductor of heat, and prevents root-burning, if the bed become too hot.

We select the firmest side shoots, cut them with a small portion of old wood, or heel, pot singly in 2½-inch pots, but if smaller pots are used so much the better. Potting the plants singly is of the greatest importance, as *Centaureas* will scarcely endure being divided: in fact, their roots are more tender than those of any other plant I have ever handled.

We prefer a bottom heat of from 90° to 100°; the frame is never shut up closely, excepting during strong winds and bright sunshine. We then close up and shade.

Careful ventilating and watering are as essential for success in striking these as for all other kinds of cuttings. If well watered when put in they need but little more watering until they are rooted, especially if grown in dung-heated frames.

We have just repotted three hundred strong plants of *Centaurea candidissima* which were struck in September last, and they are a fine stock of plants that many nursery-men would be proud of.—W. CLARK, *Ruby Gardens*.

In reply to "J. A." I always operate upon my plants in September, and I will state the method which I have successfully practised for the last two seasons.

In the first place, I do not use bottom heat, but strike the cuttings in a cold frame, which I place on the bare ground with the back turned towards the midday sun. I then cover the space inside the frame with coal ashes to the depth of 4 or 5 inches, and in this material I plunge my cutting pots up to the rim.

Having completed this part of the work, I next take off the cuttings, which I prepare in the following manner:—Unlike "J. A." I am not particular in having a piece of "heel" attached to the base of the cutting, for I invariably find that roots are emitted much sooner and better without it. I cut the shoot clean across with a sharp knife, and remove two or three of the lowest leaves with the knife. Each cutting is inserted singly in a small 60-sized pot, made tight and firm, and tied neatly to a small stick. To the latter precaution I partly attribute my success, for it prevents the cutting from flagging so much as it would otherwise do.

No. 363.—VOL. XIV., NEW SERIES.

The cuttings are then thoroughly watered, plunged in the frame, and kept close until they have rooted, and are fit for potting, which will be in about three weeks.

After potting, the young plants are again placed in the frame, and kept close and dry until their roots have penetrated the new soil, when they are gradually inured to the air, so that in a short time the lights may be entirely removed in fine days. These plants, if kept in a dry airy place during the winter, will be fine for bedding-out in April or May.

The compost I make use of is formed of two parts mellow loam, one part silver sand, and one part leaf mould or cocoa-nut fibre refuse.

The chief error which I believe most people fall into in propagating the *Centaurea* is affording a too copious supply of water, for I do not know of any plant so impatient of moisture as the *Centaurea*. I never sprinkle my cuttings after they are plunged; in fact, they are rarely watered more than once from the time they are put in until they have made many new roots in the fresh soil in which they are potted; for I find that the moisture from the ashes keeps them sufficiently moist.

I have no doubt the method practised by "J. A." answers perfectly well, but the great advantage which autumn propagation possesses is the abundance of cuttings that may be obtained at that season, and it likewise obviates the necessity of keeping a number of plants in pots for the purpose of affording cuttings.

I am not sure if it is generally known that this plant is thoroughly hardy, but with me it withstood the winter of 1866 quite uninjured. I, however, prefer planting every year, as the young plants have a much finer effect than the old ones.—H. C.

I THINK *Centaurea candidissima* far superior to *Cineraria maritima*, useful as it is. I have in damp weather seen the *Cineraria* become nearly green, not so with the *Centaurea*. I have often wondered that we have not seen it more frequently employed for bedding purposes. My experience with it is as follows:—

On the 10th of last October I lifted my plants of *Centaurea candidissima*, took off every side shoot that I could, cut off with a sharp knife the lower leaves, and inserted the cuttings singly in well-drained pots filled with a mixture of sound loam, with three parts sharp river sand. I potted the old plants in the same compost, placed them and the cuttings in a pit, gave a good watering to settle the soil about them, and kept them dry afterwards, with just sufficient warmth to prevent injury from frost. I have examined them from time to time to see how they were progressing. I find to-day (March 4th), that they have all filled the pots with roots, and are ready for being placed in larger pots. By the time for planting-out I expect to have as fine a lot of *Centaurea candidissima* in 5 or 6-inch pots as one could wish. I have no doubt that a spare shelf at the back of a greenhouse would be a suitable place for them, where they could be kept dry and free from drip, which latter is very injurious. I see to-day in a sheltered border some plants of *Ruby Bicolor Calceolaria* that have

No. 1015.—VOL. XXXIX., OLD SERIES.

stood through the winter, so far looking quite healthy and likely to survive, unless we have some very severe weather.—
M. H., *Acklam Hall, Middlesbrough-on-Tees.*

CORDONS—BUSHES—PYRAMIDS.

I HAVE no desire to enter the lists in controversy with such a pomological giant as Mr. Rivers, but to state my experience, and venture an opinion to other amateurs, who, like myself, may take an active interest in fruit-growing. That what I assert may go as nearly as possible for what it is worth, I will commence by stating that I have about twelve hundred fruit trees in various stages of growth, of these forty-six are cordons, and about one thousand bushes and pyramids. I have had only five years' experience, but during that time have studied Rivers, Du Breuil, Bréchant, and others, besides the weekly contents of "our Journal." In learning the theory and practice, I have been more or less assisted by Mr. Rivers, the Rev. T. C. Bréchant, Messrs. Abbey, Pearson, and a host of gentlemen's gardeners, whom I take this opportunity of thanking.

In January, 1865, I had a piece of old meadow land trenched, and planted with 122 bushes on Paradise and Quince stocks, as advised in the "Miniature Fruit Garden" (twelfth edition); of these fourteen are Cox's Orange Pippin. In 1866 the produce was one Apple; in 1867, 115, or two pecks, instead of a quarter of a peck each. Sixty-three trees have as yet produced nothing, twenty-three half a dozen fruit each or less, and twenty-three bore ten or more last year; but I must add they promise, with few exceptions, to do grandly in future.

One word as to labour. Mr. Rivers says that "an active man can lift and replant one hundred in a day." According to my experience, to dig up carefully, trim the roots, and replant in quincunx order or straight lines, one hundred trees are a good day's work for two first-rate spademen.

I much prefer bushes to pyramids for everything except appearance. Whilst M. Du Breuil says the fence must be 7 feet high, and Mr. Bréchant 10 feet at least, Mr. Rivers much surprises me by recommending a wire fence so low as 4 feet for diagonal cordons; planted at an angle of 45° the trees when 5 feet long would be at the top, and though their roots are so close together they will send up shoots 4 feet long in one season, in spite of biennial root-pruning. However, the "average of one dozen fruit each, of very fine quality," certainly is "not a bad return for good cultivation"—such a return as I never have had or expect to have so early as in "the second year after planting;" eighteen Pear trees on a boarded fence having given me a total of only twenty-two fruits last season, though the same sorts do well here as bushes. My crop, no doubt, was unusually bad, but I venture to think that half a dozen each is a far more probable average for such young trees.

The directions for the cultivation of cordons are delightfully simple, the promised produce most seductive, but "all is not gold that glitters." "Cut down to two eyes which next summer produce two shoots, then pinch to four leaves," &c., but sadly too often one of these eyes declines to bud in spite of all you can do, and the only cure is to cut "that melancholy single shoot" down to two leaf buds next winter. Cordons, moreover, require constant attention. Few men are permitted by their occupations to go round their garden every morning with scissors in hand. Most men take a few weeks' leave of absence during the summer, when, unless they can leave them in experienced hands, woe betides the cordons. Some carefully nurtured shoots become a prey to caterpillars, others become so rampant as to defy any amount of pinching, twisting, and "partial fractures." Moreover, all drawings that I have ever seen of cordons represent the growth as equal on the upper and lower sides, whereas, in fact, it inclines mainly to the upper.

Nearly as much space in "our Journal" might be taken up by stating the objections to cordon training as has been occupied by statements in its favour. I would, with all deference to their advocates, amongst whom I rank myself under certain conditions, give a word of advice to those amateurs and market gardeners who may intend planting on this system, 1st, Don't (as *Punch* says to those about to marry), till you have seen some growing and grown for some time. If you have not this chance plant but by way of experiment. 2nd, On the authority of M. Du Breuil and Mr. Bréchant, to which I humbly add my own, do not attempt to grow them on a fence less than 7 feet high (10 feet would be far better). 3rd, On the same authority, do not attempt to dispense with the guide rods. 4th, If you cannot give them constant attention (impossible, I

should say, for market gardeners with their press of work), or if you cannot during your summer absence leave them in charge of an experienced person (improbable, because at present few understand their culture, and practical men have several reasonable grounds against its adoption), leave cordons alone altogether; and, 5th, until English nurserymen will give us maiden trees at something like French prices, instead of from 6d. to 1s. each, we had better let alone the French system. Still, I say, if you have time and inclination, grow a few as an agreeable hobby, but do not expect too much produce or little trouble.

Some readers may infer that I have made a "regular mess" of fruit culture in general, and have read and learnt to but little purpose. I, therefore, feel bound to add that I have trees that for production have equalled, and for shape excel the photographs so familiar to fruit-growers; dwarf trees, overfruited for experiment, have been the admiration of many to whom I have had the pleasure of showing them, and fruits from trees purposely much limited in the number allowed to ripen, have excelled in quality any I have yet seen; but it would be a pity, if out of one thousand trees I could not obtain something worth looking at. As every tree is numbered, its culture and produce separately noted, I can, if such knowledge be thought worth acquiring, state what each sort produces, and the peculiarities of its habit and character.

I have thus honestly given the results of my experience by way of caution to amateur fruit-growers, and in so doing have to my ability discharged a debt of gratitude which I owe to many an amateur and gardener who has depicted his successes and failures for my benefit. I will conclude with a quotation from Mr. Bréchant, which is to my mind the best thing written on cordon training. "For an amateur to take up cordon training, and to endeavour to practise it, irrespective of the exigencies of our rainy skies, and to expect results attainable in other dry and sunny localities, is simply absurd."

I hope as years wear on to give, if you care to have them, further notes on my rapidly increasing plantation of fruit trees.—C. C. E.

[We do care to have them, as we always covet details of practice intelligently conducted.—Eds.]

AIR-ROOTS ON VINES.

If the readers of this Journal are like myself, any experiment connected with the Vine will always be of interest to them, even if it only confirms that which has been previously advanced by other writers.

For the last two years I have made notes of observations taken during a succession of Vine-forcing in order to obtain some reliable information as to the causes of air-roots on Vines, the effect they have, and the treatment to prevent their appearance. As a rule, Vines that are forced put forth more air-roots than those that are not forced, or which are allowed to grow naturally. This I attribute to the unequally balanced action between the roots and branches, in other words, to the deficiency of supply as compared to the demand brought on by the unseasonable time at which the roots are called upon to act, and the great difficulty experienced in keeping the temperature of the roots on equal terms with that of the branches. I am more convinced of this being the case, from starting a fresh house of Vines every month from December to April, and as the season advanced the proportion of air-roots diminished.

Over-cropping is another very frequent cause of the production of air-roots, whether the Vine is growing naturally or artificially. I have found that if a Vine is placed in the most favourable situation, both for its roots and branches, it does not root or grow with the same vigour every year, consequently it is not always able to carry a full crop, but it is too much the custom to take one from it regardless of consequences; this weakens the constitution, and Nature seeks to assist herself by the production of air-roots.

This brings me to the second part of my subject—viz., the effect air-roots have upon the Vine. Although I believe they do afford a slight amount of assistance to the Vine during a certain stage of its growth by feeding upon the moisture in the atmosphere of the structure, yet I have proved that to allow them to grow is to bring disappointment to the cultivator and injury to the Vine, for as soon as air is admitted more freely, and the atmosphere kept drier to favour the colouring process, the air-roots dry up and die. The Vine thus receiving a serious and sudden check, inferior-coloured Grapes are the consequence.

Having convinced myself through experiments that stem-roots upon Vines are an evil, I have found the following treatment effectual in lessening the tendency of the Vine to produce them.

First, take care that the soil of which the border is composed is thoroughly well drained, and of such a nature that when the roots are penetrating it for food they may take up that which is most suitable to their requirements. I have found a rich soil injurious to the Vine when young, and if the latter is treated on the restrictive system it induces a plethoric condition of growth not required for the production of good Grapes. The soil had better be too poor than too rich. Encourage the roots near the surface, and if they are in outside borders, protect them from frost and superfluous moisture.

With regard to Vines intended to be forced, great care should be taken to induce root action as soon as the buds burst into leaf; for if the leaf become developed before the roots can supply it with sap, it must receive some injury from the want of nourishment. Avoid a high internal temperature and an excessively moist atmosphere, especially in dull weather and in the early stages of the Vines' growth. When the surrounding atmosphere is cold, and strong winds prevail, root action is less active, especially in outside borders, through the temperature being reduced. At such times I have found it beneficial to reduce the interior temperature in proportion also, which keeps the demand and supply upon more equal terms.

There are several other things besides those above mentioned, but of a less serious character, that will arise during the progress of the Vine through its different stages of growth, but the effect they have upon air-root production must depend in a great measure upon the skill with which the Vine is cultivated.—THOMAS RECORD, *Hawkhurst, Kent*.

FLOWERS OF OTHER DAYS.

"Be not the first by whom the new is tried,
Nor yet the first to lay the old aside."

I AM rejoiced to see that several of your correspondents are ably fighting the cause of that shamefully and sadly neglected class, the herbaceous perennials and biennials. It is marvellous to me how any real lover of flowers can do without them. I have nearly as many as my little garden will hold already, but mean to go on cramming it as long as there is any available space. The difficulty is to get hold of many of the best old-fashioned plants; they are almost lost to cultivation, and it is only by making friends with such lovers of the olden time as your correspondent Mr. Mellish seems to be, that you can obtain these herbaceous gems.

However, I think we are waking up, and fine fellows though they are, we are not going to let the ribbon gardeners and sub-tropical florists have it all their own way, and we shall soon, I hope, see some of those glorious old herbaceous gardens, the beauties of which Hill and Milton loved to describe, and which Curtis delighted to paint.

To all lovers of beautiful herbaceous plants let me recommend *Michauxia campanuloides*, a tall Campanula-like plant, with large conspicuous white blossoms, somewhat like a Turk's Cap Lily. I saw it last autumn, at Glasnevin, several feet in height and making a magnificent appearance. I have just been planting out a bed of strong young plants from which I promise myself much pleasure. It is a biennial, and grows very freely from seed.

Saponaria ocyroides and *Silene alpestris* make most lovely pink and white beds in May, perfect sheets of bloom.

No herbaceous plant has afforded me more pleasure this season than *Primula denticulata*. I have several plants now almost smothered with trusses of lovely pale mauve flowers. One plant which has been out in the open border all the winter, with the protection of a hand-glass during severe frosts, has as many as seventeen or eighteen trusses of bloom. It increases with great rapidity.

Primula purpurea, a closely allied but very distinct and lovely species, is quite hardy, and comes into flower as soon as *P. denticulata* is over.

Primula altaica, or *amœna* as some florists call it, a species closely allied to the common Primrose, is now very lovely, its large mauve flowers with a yellow eye come in such dense masses as almost to conceal the leaves. I always have a bed of *Primula cortusoides*, and very beautiful it is to look at, and last year I tried a bed of *Primula involuerata* (Munroi), and was not at all disappointed. Its pretty French white flowers

formed a pleasing contrast to the almost magenta hue of its congener, *P. cortusoides*. I have succeeded in keeping *Primula erosa* (Fortunei), out in the open border all this winter with the protection of a hand-glass during severe frost, and it is now coming into bloom.

Primula cortusoides amœna, in my opinion quite distinct from *cortusoides*, has no protection at all, and is coming up green and healthy, and *Primula verticillata* is alive and well.

Can any of your readers tell me where to obtain the old "Double White Cowslip?" I have tried in vain. Mr. Youell, of Yarmouth, used to have a large stock, but has lost them all.

Sophora [*Baptisia*] *australis* is another beautiful old-fashioned flower I wish to procure, and I should like to hear of some one who grows *Narcissus triandrus*.

Every one should grow that lovely little perennial, *Sisyrinchium convolutum*. It keeps opening a succession of yellow stars all the summer.—H. HARPER CREWE.

AMONG the too-much neglected shrubs are the following:—

BERBERIS JAPONICA.—I have about thirty plants, some in warm, some in cold situations, all of them in a good, light, but unprepared soil, and some of them exposed to the whole day's sun, but I find them do about equally well in all situations. The winter of 1866-67 damaged a few of them slightly, but they have all recovered. They are now in bloom.

BUXUS BALEARICA.—Fourteen plants were all damaged, some killed outright, and most of them to the ground, by the hard frost of January, 1867. Only two, in very sheltered positions, now look tolerably healthy, and I fear the plant is one of the least hardy evergreens.

Among the evergreen shrubs, not *Couifera*, which here suffered most from the severe winter of 1866-67 (my thermometer was about zero), I may enumerate *Arbutus*, *Bays*, and *Laurustinus*, both sorts, nearly all cut to the ground; *Colchian*, and in some places common *Laurels*, *Garrya elliptica*, *Euonymus japonicus aureus* fol. var., and *Double-blossomed Furze*; the last-named alone being in most cases killed, not twenty out of fifty plants remaining.

Two young *Cork* trees were undamaged. A *Piptanthus* left out without any protection, though killed down, survived and blossomed last summer better than plants kept in the house.

I will with pleasure give you my experience of other shrubs if you desire it, but I especially wish to direct your attention to the little-known hardiness of *Chamaerops excelsa*, a name which I hope to see, and which deserves to be, at the top of your next article. I planted one in the autumn of 1864, and another in 1865, the former in a somewhat sheltered, the latter in an exposed situation. I have never given them any sort of protection. One was somewhat damaged in January, 1867; the other, the larger, not in the least, and it grew strongly last summer. My only *Chamaerops humilis*, also unprotected, was much damaged, but will recover.—A SUBSCRIBER.

AUCUBA JAPONICA.

IN reply to "HARRY'S" inquiry in the Journal of the 5th inst., I beg to state that artificial impregnation of the flowers of our old *Aucuba* is unnecessary, moderate proximity of the male plant being quite sufficient.

There may be seen here at present two good-sized plants of our old favourite loaded with clusters of large, beautiful, scarlet berries. These bushes were fertilised by a small plant in a pot being placed a few feet from them when in bloom last spring, and the result proves to be perfectly satisfactory; for, not only are the clusters largely distributed on the outside of the bushes, but they are also to be found in masses in the interior; thus showing a wonderfully minute and extensive distribution of the pollen.—J. SAYERS, *Gardener to T. Bewley, Esq., Rockville, Blackrock, near Dublin*.

EFFECT OF CROSS-IMPREGNATION ON SEEDS.

I HAVE the Runner Kidney Bean Zebra; and should your correspondent "LANSLOWNE, Worcester," page 191, March 5th, not succeed in obtaining them nearer home, I shall be happy to present him with a few—six dozen or so, if he will tell me how and where to send them, and will pay carriage. A few would go by post. I have another variety of the same character of Bean, whose ground colour is dark (a sort of mahogany), with the same black stripe.

This subject has brought to my remembrance a singular freak of nature which occurred in my garden last year. I received from the Royal Horticultural Society, through our local Society, my share of a distribution of choice seeds, &c.; and among them were some half-dozen small black Beans, named Black Wax Runners, about the size of the white dwarf Bean. These I planted carefully; and in order to make a line, I put in with them some fine large white Runners. Guess my surprise, on opening the ripe pods of these latter for seed, to find jet black Beans the full size of the white ones. I can only account for this by supposing the bees to have been busy among the blossoms, and to have carried the pollen from flower to flower. Would this be your opinion, and is it a rare occurrence?—ALF. TIDY, *Manor Cottage, Noirmont, Jersey.*

[Mr. T. A. Knight, the distinguished first President of the Royal Horticultural Society, observed a similar effect produced on Peas by cross-impregnation.—Eds.]

FRENCH ASPARAGUS CULTURE.

ASPARAGUS, as everybody knows, is grown very extensively in France. Every individual in possession of a piece of ground devotes a portion of it to its growth; so that, travel where you will—from Dunkirk to Perpignan, or from Strasburg to Brest—it is more or less seen. In fact, everybody grows, cuts, and sells it. The department of Seine-et-Oise, however, is the most talked-of portion of France, as having produced the largest heads of this vegetable. The Lhéran family of Argenteuil have shown them 4 inches in circumference; but I do not look on this as the criterion of good cultivation—quite the contrary, as I know from experience that those overgrown heads of Asparagus, like all coarse overgrown vegetables or fruit, are not near so relishable and well-flavoured as the medium-sized, that have been grown on more wholesome and less-manured ground. Many French gourmards, however, think otherwise, and relish these coarse Asparagus with great gusto, more particularly when they hear that the Imperial Horticultural Society of France has crowned them with a gold medal, which they do frequently.

It is not my purpose here to criticise the flavour of this wholesome vegetable. Some are very fond of it; others, again, have an aversion to it. I think all will agree that we have a much more wholesome and nutritious vegetable in the Marrow-fat Pea—altogether a cheaper and more serviceable vegetable for the people. This is a vegetable quite unknown amongst the people of France; so also are the Scarlet Runner Bean, the Sea-kale, a good spring Cabbage, and Broccoli; scarce also are a decent Onion, a good Potato, a fine Cucumber, and—about the most useful of all for poor people—a good Leek. The Asparagus Kale, a most profitable hardy spring vegetable—nearly as good to my mind as Asparagus itself—is never to be met with. A good Turnip also is a scarce vegetable. These are a few of the good things that are to be found in nearly every cottage garden in Britain, while in France they are either scarce or nearly unknown. As a rule, the vegetables most common in England are scarce in France, and *vice versa*; but not to the same extent in the former, for I know of no vegetables common in France and comparatively scarce in England, except Asparagus and Lettuce, and the latter only so in winter. I had nearly forgot to mention the Rhubarb as also another excellent addition to our English spring dainties when well grown. I remember my wife once giving a spoonful or two of this vegetable, stewed with sugar, to a Frenchman, who declared he never tasted anything so nice in its way; eaten as he ate it—with a piece of bread, and with a flavouring of Cloves—it is certainly as nice as stewed Pears or Apples.

The culture of Asparagus having become quite a mania in France, it may reasonably be supposed that the mode of culture adopted by the French gardeners is perfect. I believe it to be so; but, at the same time, the soil of Seine-et-Oise is peculiarly well suited to the requirements of the Asparagus root; just as the soil in the midland parts of France is suited to the requirements of the Vine; and with the hot sunny days and cool dewy nights, with ordinary care in destroying weeds, and a few other minor attentions, it lives and flourishes to a very prolific degree, and continues doing so, with little or no manure, for thirty years. I have seen the roots of Asparagus 8 feet deep in the inexhaustible calcareous beds of soil so common in this department. It will be seen, then, that the system in vogue is very greatly aided by nature, whatever may be said to the contrary; of course I am speaking of out-door culture.

In forcing an *aspergerie*, as it is termed here, or a field of Asparagus, if Vines have been growing on the land previously, no outlay is necessary further than lining the ground off and throwing out trenches 4 feet apart, measuring from the middle of the trench. The depth is regulated according to the consistency of the soil—or, in other words, the lighter the soil the deeper the trench, and the heavier the soil the shallower the trench; in either case it must not exceed 18 inches in width; this allows the ridges to be cropped with light crops of Haricot Beans, early Potatoes, and the like.

Every grower raises his own roots by sowing selected seed. The largest and earliest ripened seeds are chosen. A bed of sandy unmanured soil is lined off, forming little furrows 12 inches apart, and the selected seed finger-and-thumbbed in at least 4 inches apart. After the rake has been drawn over all, the seeds will be 2 inches from the surface. This operation is done on a dry day in February. By the end of March, a hoeing before the seeds germinate tends to keep the seed beds clear of weeds, after which the young plants soon begin to show themselves above ground. The end of April and beginning of May bring hot dry weather. A slight mulching with decayed manure is now applied. After this nothing more is required but a little hand-weeding and repeated waterings in very hot weather throughout the year. At the period when they may be termed yearlings with half an inch of growth, which will be about the end of March, is the time when the planting in the *aspergerie* takes place.

The previously prepared trenches, having been well seasoned by a winter's frost, are now run over with a coarse rake, levelling the coarse clods of soil, which fall to pieces like slaked lime, and at the same time a good portion of this aired soil from off the ridge is sent into the trench. With this and a little rotten manure, little molehills are formed 16 inches apart. Three persons are necessary for the work. One takes his place at the seed bed, lifting carefully with a fork the young roots and laying them in a basket, screening them from sun or winds with his blouse, and carrying them to the principal in the trench. This individual takes them one by one, and in a very neat and expeditious manner lays each root on a molehill—every root being laid out like an expanded hand. The third individual comes behind with a basketful of dry prepared rich soil. A good double-handful is placed gently over each root, and the planting is terminated.

About three weeks after this the young roots are pushing vigorously, and the three-pronged hoe-rake is again brought into use and run through on the ridges, allowing again a little of the soil to fall into the trench. The trenches are then in turn gone over with the same instrument or a common draw-hoe, levelling the soil, and cutting up at the same time any weeds; any such found around the crown of the Asparagus root are pulled out with the hand. With these slight earthings-up, and an occasional hoeing, nothing more is required for this year. The ridges, of course, are planted with Potatoes, salads, Beans, or Carrots, which require at the same time attention.

In the month of December, if a good day can be found, the soil that has accumulated on the roots by the hoeing and walking on the ridges, is taken away by a short broad-bladed hoe and laid again on the ridge. The crowns of the Asparagus are laid bare, and again a handful of light rich soil is put on them. Some prefer a quantity of rotten manure for this purpose. Nothing more is done till the month of February of the second year, when the ridges are again dug and cleaned for the year's cropping.—H. K. (in *Gardener*.)

(To be continued.)

MUSHROOM CULTURE.

I SEND you a box of Mushrooms, and as my mode of treatment is somewhat different from "G. Egerton's," and I have practised it successfully for many years, a few explanatory words may be acceptable to some of your many readers.

In the first place we procure as much horse dung, long and short together, as will make one-half the bed; we next obtain enough droppings to cover the bed all over 2 inches thick; then we throw each together in separate heaps. In a few days the heap will require turning, which is repeated here three times during a fortnight, or, if thought necessary, a fourth time, when it is thought sufficiently sweetened.

We make the beds in the following manner:—We use, as fresh as can be obtained, enough dung from the yard to make the bed nearly 1 foot deep, shaking out some of the longest

bitter, beat well, and cover it with an inch of soil, which is also well beaten down. We next put on the dung, as mentioned above, well beating it down as the work proceeds; then we finish off with the droppings, leaving all as firm as possible. In nine days or so the bed will be fit to spawn, or have a temperature of from 75° to 80°. We soil it at the same time, leaving it as firm and smooth as we can.

I should mention that our Mushroom house is a cellar, and the beds are all made on the floor, some in the form of a ridge and some nearly flat. We cover them with hay, and never water till they decline bearing.

I do not suppose there is anything new in this system, for it was taught me by my father, who was under the late Mr. Mearns; but any of your readers who may try it will not be disappointed with the result, as the sample sent will, I think, be sufficient to prove.—*JOHN GOGAN, Gardener, Lea Castle, Kidderminster.*

[The Mushrooms were well grown, densely crowded, and of all sizes from that of a pea up to that of a crown piece, but there is nothing new in the system of culture; it will do well under the superintendence of an experienced man, like other rough-and-ready modes, alluded to by Mr. Fish and others. One circumstance much in your favour is having the bed in a cellar with its next-to-uniform temperature and moist atmosphere. Beginners we would advise to prepare the dung a little more, and have it dried, without too much heating it. Too much heat is that by which most beginners lose their crop.—*EWS.*]

MY ORCHARD-HOUSE JOURNAL.

It is, I think, probable, that some of your readers may be interested in the periods of blossoming, setting and swelling the fruit, and other matters pertaining to the culture of a large collection of orchard-house trees in pots, the trees from five to fifteen years old. I propose, therefore, at intervals to give in your columns a short journalistic account of the doings of my trees, commencing this spring of 1868, and continuing it, if permitted, through the season.

Feb. 5.—The "Mumé," a Japan Apricot in full bloom—a charming tree. Its calyces are of a deep crimson, and its petals delicate pink. This is the earliest of all stone fruits. Last season it blossomed in January, towards the end. This interesting tree bears a small compressed fruit, yellow, and something like an Almond in shape; it is acid and bitter, and although the tree blossoms so early its fruit is not so early as Oullins Early Peach Apricot.

Feb. 26.—Apricots in full bloom. The old trees perfect masses of blossom—most beautiful. Seedling Apricots, of which there are some forty in number, differ by several days in their periods of blossoming, thus giving hopes of variety in their fruit. They are full of blossom, and full of interest.

March 9th.—Apricot blossoms have shed their petals; every blossom seems to have set, so that the thinning of the fruit will be a tiresome business. The seedling Apricots vary much in their time of blossoming, many are now in full bloom, while others, standing side by side and under the same treatment, have not opened a bud.

The blossom buds of Peaches and Nectarines are bursting fast. I observe to-day a curious anomaly, the Lord Palmerston Peach, one of the latest, is nearly in full bloom—earlier than any other. Its large Anemone-like flowers, like those of its parent the Pavie de Pomponne, are most conspicuous and ornamental.—*T. R.*

WARNING TO INTENDING EMIGRANTS.

WHAT a happy people we Britishers ought to be; but we have been trudging on in the easy ways so long, that we do not wait to think of the comforts and blessings we daily enjoy, and until we go to foreign lands, or the distant colonies, and are knocked about "from pillar to post," and worn out in fighting continuous disadvantages, we cannot thoroughly realise the fact that ours is, indeed, "the happiest land upon earth." We hear continually of the advantages possessed by other lands, and certainly "one side of the story is good until the other side is told," but in sober truth I wish to warn those who are needlessly discontented with their lot here, and to prevent them, if possible, "jumping out of the frying pan into the fire." As I am now addressing my brother horticulturists, I shall confine myself simply to horticultural subjects, and endeavour to show a few of the drawbacks as exemplified by my own ex-

perience in various parts of North America, both in the British colonies, and in the United States.

A careful and energetic person in the western part of the State of New York, some years ago planted an orchard of dwarf Pears. They were fine trees, well planted, and the ground in excellent order. For two seasons they did well, and promised handsome results, but there came one of those fearful winters sometimes experienced in those latitudes, when the mercury falls to many degrees below zero, and out of nine hundred trees not six survived. The hopes of the planter were destroyed at one sweep. The intense frost had killed all the Quince roots; some of the trees had sap enough in them to open the buds, and then they went off as though a fire had passed through them.

Another cultivator had a plantation of native Vines, in number about four thousand. They had grown well for two seasons, and a similar winter to that just mentioned destroyed them all. The ground had frozen early in the autumn after heavy rains, and was surcharged with moisture. During the month of January a rapid thaw set in, and the plants were heaved up, all the fibrous roots being broken, and nearly all above ground. Before they could be covered or replanted the ground froze again; and as almost the whole plant, root and branch, was exposed to the action of frost and sun, the result was the total destruction of the vineyard.

Another fruit-grower had a fine young Apple orchard, six years planted, and in consequence of the severity of the weather the field mice were very much put to it to find food. The result was, that the vermin barked nearly every tree in the orchard, and most of them died, and even the survivors might have gone too, for all they were worth afterwards.

An enterprising English farmer, who has had plenty of experience in the management of hedges at home, has been trying for some years past to grow a live fence round his garden, but all to no purpose. Do what he may the mice find their way to the plants every winter, and girdle them most effectually. So persistent and so numerous are they, that the hedge project has had to be abandoned. His case is not a solitary one.

All these unfortunates are careful and tidy cultivators, and their mishaps have come upon them through no neglect on their part, but have been positively unavoidable, having been brought about by natural causes.

With an average temperature during the winter months of about 10° Fahr., a gardener can well imagine what an amount of boiler power and piping must be required to keep the frost out of glass structures, and at all the establishments with which I am acquainted the fires have to be made up once or twice during the night. Then, again, a great heat must be kept up for fear of a sudden change outside, and the dryness of the atmosphere is productive of all sorts of insect pests. Nowhere in America have I seen such green, short-jointed plants, as are to be found in English houses. During the winter the American plants look drawn, and pale in colour.

As regards out-door operations, for at least four months in the year not a spit can be turned, and crops of every kind must be under cover before the ground freezes, and it often happens that for the best part of six months stern winter holds everything with an iron grasp.

Then, when seed time comes, there is literally no time for work. Within a fortnight everything must be done, and it is then a long time to wait for the crops to come in, for there is no relay or succession of garden products through the winter as in England. The summer comes at once, and with it intense heat, and often protracted drought, or else such violent rain storms as prostrate everything, and cause much damage to growing crops.

Then, the grower of fruit has the Tent Caterpillar, the Codlin Moth, the Curculio or Plum Weevil, the American Blight, the Fire Blight, the Peach Borer, the Gooseberry Caterpillar, and many other enemies to battle with. The grower of vegetables the Striped Bug, the Chinch Bug, the Squash Bug, the Onion Maggot, the Cockchafer, the Cut-worm, the Sphinx Caterpillar, and many other desperate and resolute foes. The agriculturist has to fight with Rust and Smut, Hessian Fly, Wheat Midge, Cut-worm, Grasshopper, and many other pests; so that in addition to the extremes of climate, there are many other enemies to meet.

Now, I do not mean to say these difficulties are insurmountable, but what I wish to show is this, that in running away from discomforts and adversities at home, we do not know how much greater we may meet by going abroad. After many years' experience, my advice to all is, *STAY AT HOME.* I shall be glad

to reply to any inquiries that intending emigrants may wish me to answer, but at the same time would say that my decided opinion is recorded above.—W. T. G.

TRANSPLANTING LARGE TREES AND SHRUBS.

The practice of transplanting large trees and shrubs being very general, I will offer a few remarks on the simple contrivances which I have found sufficient for the purpose of removing trees and shrubs of from 15 to 30 feet in height.

The appliances necessary, in addition to the usual spades, picks, shovels, &c., are a couple of picks with one end for the purpose of working under the ball; two or three ropes; half a dozen or more slabs of various lengths, from 18 inches to 3 feet, notched at the ends to hold the rope (these are used in binding the ball of earth, but in some soils this need not be done, whilst in others it is absolutely necessary to secure the ball in the best possible manner); and a sledge of sufficient size and strength: $4\frac{1}{2}$ feet long and $3\frac{1}{2}$ feet wide is a good useful size.

FIG. 1.

a, a, Staples to fasten the horses to. *b, b*, Chains with rings for binding on the sledge. *c, c*, Ropes for the same purpose. *d, d*, Rings for lifting with jack. *e, e*, For struts—never used.

The sides or runners of the sledge (*fig. 1*), should be of good well-seasoned timber 6 inches by 4, and the ends well turned up. There should be four slats or bars across, dovetailed or morticed into the sides, and about a foot from each end an inch iron rod. On the outside of the side pieces, at a convenient distance from the ends, should be fixed good strong staples, *a, a*, of sufficient size to admit of almost any hook for the purpose of attaching the horses. Inside the ends, at one end of the sledge, two chains, *b, b*, 2 feet long, with a ring at the end, should be attached one at each side. At the opposite end two ropes, *c, c*, one at each side, and 3 yards or more long, should be properly fastened. These are for binding the plant on the sledge, which is done thus:—

The ropes are put through the rings at opposite corners, across the ball, round the bole of the tree, drawn tight, and made fast. Hay or some other soft substance must be used to prevent the ropes barking the plant.

In opening a trench round the plant to be removed regard must be had to the size and age of the tree, the nature of the soil, and other circumstances. It is, however, advisable to commence a trench which is wide enough, for the work will be done much more easily and expeditiously by having sufficient room to work. Two or three feet on one side of the plant

should be left untouched until the sledge is put under; then that portion of ground must be cut through, and the plant will sink down on the sledge. Open the trench to a good width, and be careful to go sufficiently deep to be beneath the fibrous roots. A depth of 3 feet is usually sufficient to allow the bottom of the ball to be cut, so as to admit of the sledge being put under.

In working out the plant, work at the bottom of the trench and beneath the ball with the pick; then reduce it with the same tool, which should not be too pointed, otherwise it will be apt to split the roots, on the preservation of which in a very great measure depends success.

Having reduced the ball to the desired size, work clear beneath. It is, however, a very good plan, after having worked some distance under the ball, to shore it up with anything at hand; a good stout slab placed along the side, and propped in the centre, is as good as anything. After placing the sledge under the ball, cut through the part left, secure the ball with the ropes, and it may then be drawn to the place where the tree or shrub is to be planted. If, however, the plant be likely to sway over, two ropes held by men will prevent its doing so.

FIG. 2.

1, Grooved wheel. 2, Handle. 3, Hook for lowering. 4, Hook for lifting. 5, Hook for fastening chain when shifting the handle. 6, Lifting chain.

Arrived at the plant's destination, the horses should walk through the hole, stopping when the plant is in the centre. Then drive a strong crowbar firmly into the ground, put a chain round the ball, placing a good broad stout slab betwixt it and the earth, make the chain secure to the crowbar, and the horses will draw the sledge from under the plant.

The same care must be taken in preserving the roots in planting as in taking-up; spread them all carefully out, working fine soil well in amongst them, and ramming it firmly down. Proceed in this manner until the tree be planted; then give a good watering and mulch. Stones are as good as anything for the purpose, either for summer or winter.

Three stakes of this shape *1* should be let into the ground at the time of planting, the T-part downwards. Galvanised iron wire should be fastened to the tops of the stakes, which should be level with the surface of the ground, and the wire should be fastened a good distance up the tree to prevent the wind waving it.

A far better plan than drawing the plants on the sledge is to have what we name tall jacks (*fig. 2*). They consist of a foot, an upright, a grooved wheel on the top, and a handle with two hooks, one about 4 inches, the other about 6 inches from the upright. A hook is also fastened in the upright about 4 feet

from the bottom. The jacks are about 8 or 9 feet high. A chain passes over the grooved wheel on the top, the hook is made fast to the weight to be raised, the hook nearest to the upright on the handle is hooked in one of the links of the chain, and the handle is worked in the same manner as a pump handle. When the handle is down the chain is made fast to the hook in the upright until the handle is raised. The hook farthest from the upright on the handle is for letting the weight down. When these jacks are used two are required, one on each side of the plant, and a strong staple is required in each side of the sledge to fasten the hooks to.

When the plant is lifted a sufficient height a low-wheeled truck is backed under it by manual power. The bottom of the truck is flat, and is above the tops of the wheels. The trucks used by masons will answer the purpose. Of course lifting the plant off the truck is simply a repetition of lifting it on.

With these few simple appliances a practical planter may remove plants of any reasonable size with the minimum risk of failure. I had forgot to state that the sledge should be boarded to present a smooth surface, and to prevent the soil falling from the ball.

I would feel greatly obliged for any information on the subject of transplanting.—F. FLITTON.

[The latter part of the communication, that relating to lifting by jacks, at least with their assistance, is the most important. In practice we have generally found that all binding of balls with chains and slabs is only a hindrance to a good workman. A very good moving machine that would pass through narrow gateways was shown and took a prize at the International Horticultural Exhibition of 1866. We all knew something of large planting machines where great force is used to raise the tree. Unless in particular cases, planting large trees never will answer as a matter of pounds, shillings, and pence.

For all trees and shrubs too heavy to be carried and placed in a barrow, or that are heavy enough for half a dozen to ten men to move, nothing is better than a smooth-surfaced platformed sledge, such as has been several times described. In the case of trees from 25 to 35 feet in height, nothing in general practice suits better than a pair of low cart wheels connected together by a stout axle, and a pole fixed in the centre of the axle. When the tree has been nearly loosened all round, and the axle is brought up to the stem, the pole is raised against it and securely fastened, with mats or other materials between the pole and the stem. When the pole and stem are alike pulled down, ball and roots rise in the air, and may be tied round with mats, cloths, &c., if deemed necessary, and may be set down in the new place without bruising or breaking the roots. In removing trees even of such a size, two modes may be resorted to and with much the same success. In the first place a ball should be secured by cutting a trench all round the tree at from 20 to 24 inches from the stem a year or two before lifting; secondly, if this is not done, but the plants are taken up and planted without any preparation, then the roots must be searched for and saved up to their extremities. In this case a little ball will be all the better, but a large ball is of less consequence. In any case, unless previously prepared, there are but few fibrous roots near the bole of the tree. The ball when obtained helps to secure the tree in its new position. The long traced-out roots do the same. In rather thick plantations it is almost impossible to have these long roots carried out without injuring them. Unless for producing an effect at once, it is seldom that planting large trees answers in the long run. We have helped to plant trees 30 feet in height, and to plant others 10 feet in height, and the latter ultimately beat the older ones.

DESTROYING CRICKETS.

HAVING observed lately several inquiries respecting the extermination of these pests, I write to state the means I have employed with much success, although I am sorry to own I never entirely got free of them. In small jars, such as are used for preserves, I placed at the bottom a little treacle and water, at about the consistency of limewash, and plunged them to the brim, or placed them on something to assist the enemy to his own destruction. The pots should be examined every morning, and the crickets cleared out. If the weather, or house, be hot, the mixture will need changing every third day. When it begins to ferment the crickets will not enter. The dead crickets must be cleared away, or they will only serve as food for their more fortunate cannibal relations. I may add

that in most cases these torments are brought with the cinders from the hall.—A. S. K.

POTATOES.

THERE are some things, it seems, about which it is dangerous to write. If you have the honesty to condemn certain flowers or plants because you do not think them worthy of all the high-flown characters that they have received, you are at once supposed to be influenced by some sinister motives, and your wisdom, and, it may be, your integrity are questioned. There are other things which every gardener takes an interest in; and if you write about them there are some good people who fly in the face of all injunctions to the contrary, and write you no end of letters privately about them. Such has been my experience. I wrote a few weeks ago about Potatoes. It was a very humble attempt to give my own experience of sorts which I had tried; but alas! it involved me in consequences I had not dreamt of. Letters came to me from all directions—France, north and south of England, &c., some good people evidently taking me for a market gardener, who wanted to make something out of my experience. Could I sell a few stones of this kind? a gallon or so of that? while others, with the most insinuating language, begged a few tubers of one kind or another. Now I must protest against this on behalf of my fellow workmen and myself, for it is most annoying. If one takes no notice, it is looked upon as rude; if you refuse, you are regarded as a churl; whereas if you accede, your own stock would be soon reduced to a minimum. I mention no names, because I do not wish to put people in the pillory; but I would beg my correspondents, male and female, to rest assured that were it possible I should most willingly oblige them, but that it would entail an amount of labour and time for which I am totally unprepared, and that it is neither rudeness nor churlishness that has left their letters so long unanswered.

With regard to your kindly disposed correspondent who questioned my statement about Paterson's Victoria Potato, that is quite another matter, and my reply to him is a matter of pleasure as well as duty. Had he referred to my paper I think that he would have found that I did state the soil and situation in which the Potatoes were grown. I would now supply a few facts about them which may help to make the matter clear for him. My friend, Mr. Banks, sent me last year a number of Potatoes to try, simply numbering them, in order that I might test them. From amongst them I selected one, which turned out to be Paterson's Victoria, and obtained from him a few good-sized tubers for planting. The situation chosen was light and airy, the soil a rich friable loam. The produce was very good, but not equal to Mr. Banks's in mealiness or in flavour. I take it, then, that, like all Paterson's, it is a field Potato, and not a garden one; and from a great many concurrent testimonies I gather that it is the only one of his varieties that is really worth anything. Yet what great things were said about them! His "brither Scots" gave the firm a grand dinner. He was extolled as a benefactor of his species, and a large quantity of the Potatoes no doubt was sold. It seems, then, very ungracious to say you do not believe in what all the world thinks good.

And now for another little matter personal to myself. Like my friend Mr. Radclyffe I am about to change my quarters, and am moving into a more quiet country place than that which I have for so many years occupied. I have so long, however, contributed to your pages from my present place of residence, that I must ask permission to retain the *nom de plume* I have so long assumed, and still be as before—D., Deal.

NEPETA TEUCRIFOLIA FOR BEDDING.

NOW that the tide of taste has fairly set in in favour of hardy plants suitable for bedding, it is curious that the merits of this plant as a bedder have not been publicly recognised, so far as I have seen. I have grown it in quantity for this purpose for the last seven years, and every year it gains more favour here. The individual flowers are certainly poor enough, but as a bedder it has everything to recommend it, so far as my experience has gone on a moist soil—colour, habit, and duration, when properly managed; and, moreover, it is hardy as a Willow. Its colour is beautiful and chaste in lines or masses, being a warm lavender or mauve colour, something like *Viola cornuta*, but with a shade of crimson in it. Its habit is dense and spreading, upright in the middle of the plant, and lying down on the soil all round

like the Variegated Alyssum. Its duration of flowering is from May to December without fail, and gathering in profusion of bloom and colour to the last.

Its management is extremely easy, but it must not be left to itself, as herbaceous plants are generally. It is best raised from cuttings every year, the old plants being thrown away; and with half the kind treatment given to Purple King Verbena, it will flower longer, and will rival or excel it in show throughout the season. I put in a batch of cuttings in fine soil in the open border about September, in close nursery lines, and every cutting strikes before winter. In March we transplant the young plants to where they are to remain; or if that is not practicable until bedding time, we give them more room in the border, when they make nice plants by the middle of May.

We use it in lines or masses on the panel system. Edged with a broad band of Cerastium it is beautiful; mixed with Scarlet Pelargoniums or any strong Verbena; or with Mangles' Pelargonium, Alyssum, or Saponaria, it is also fine. The Nepeta can be used with fine effect in combinations where Verbena venosa is used, and will be successful on soils where the Verbena is useless—that is, cold and heavy soils. This plant is common enough in most gardens where old herbaceous plants are not entirely banished.—(*The Gardener.*)

GALVANISED WIRE TRELLISES FOR GARDEN WALLS.

I AM about to state how we have endeavoured to avoid driving nails into walls. In those of this garden, whoever built them, very inferior mortar was used; and, besides, the wall is hollow, being built brick-on-edge, having, say, at every 12 feet or so, a solid piece by way of a tie. This might have answered the purpose had the mortar employed been made of good materials and been used when in a proper state. The question, therefore, was, how best to preserve the walls for use without going to the expense of pulling them all down and rebuilding them. In the long-run this might have proved the best mode of surmounting the difficulty.

As driving nails into the walls displaced the bricks we thought of using galvanised wire netting; but here a difficulty arose, for such rotten walls would not hold any large nail if driven in between the bricks set on edge, and nails in the solid pieces of the wall would not afford sufficient support for the wire netting. After consultation it was determined that slight battens should be fastened to the walls, each having two slight rods of iron passing through it. Where we have trees upon both sides of the walls, the battens are fastened to the walls on opposite sides by the same bolts; and where there are no trees trained against the outside of the wall, at each bolt is screwed to the wall a piece of iron long enough to pass over more than two courses of bricks. Of course, before the netting was fastened to the battens the wall was repaired, and washed over with proper lime, the glaring whiteness being softened down.

The battens are about 1½ inch thick, and 2½ inches wide, and are placed at about every 5 feet distance along the whole length. Over the top of these upright battens another, much the same in strength and appearance, is nailed down. The upper side of the wire is fastened to this; but the bottom of the wall being firm enough to hold large nails, one or two of these driven into the walls between the upright battens hold the wire quite firmly. According to the height of the wall, and how the different widths of netting suit, a space of from 3 to 5 inches is allowed between the pieces of netting. These in the 5-feet distance between the upright battens have three or four ties of galvanised wire, thus making all secure.

This method of attaching netting to the wall entirely obviates the necessity of nailing, and the danger of displacing even a single brick. The battens, as seen against the walls, may to some persons appear objectionable; but after a time the eye becomes accustomed to them, especially when it is remembered there is a good reason for their being there. In all solid-built walls there is no necessity for battens being used.

Since the galvanised wire netting has been put up I have visited several large old gardens, where the walls show that many thousands of nails have been driven into them in the course of years. Would not such walls stand as long again if they were fresh pointed, galvanised nails driven in, and galvanised wire netting fastened to them with wire likewise galvanised? In this way the netting is scarcely perceptible at 20 or 30 yards distance.

The size of the mesh of the netting may depend on taste

and the kind of trees; Peach and Nectarine trees will, of course, require a smaller mesh than Pear and Plum trees; but there is no necessity to use a less mesh, even for Peach trees, than 2½ or 3 inches. Had I my choice I would certainly use galvanised wire netting rather than deface and otherwise injure good walls, and when iron spikes or strong nails are made use of as fastenings to the walls, there cannot be any objection to its use as regards appearance. I shall be glad to learn how others may have used it.—G. DAWSON.

I HAVE had nine years' experience with a galvanised wire trellis, and I must say during the whole of that time I have never found the slightest objection to it. On the contrary, there are these advantages: training can be done quite as quickly, if not more so, than by nailing; there is a more free circulation of air about the wood, consequently it becomes more firm and ripe; and there is not that disappointment which I have experienced on going to gather a dish of fruit, to all appearance very beautiful, and finding concealed behind nearly all those which touch the wall, half a dozen or so of woodlice, which have completely spoiled the fruit for the table. This is invariably the case on our other wall, where the trees are nailed.

I quite agree with "ACESTIS," that the fruit does ripen much more regularly on the trellis than where the trees are nailed to the wall.

Again, there is no nailing and unnailing, which make the wall full of holes, a harbour for insects, and ultimately the wall must be repointed, no small inconvenience when it is covered with trees.

Respecting the complaint which "Rrctic" makes about the shoots dying, that I have never seen, unless they have been tied too tightly, in which case they sometimes die. Any metal pressing tightly against the wood will injure it, causing gum or canker.

We have also a common iron trellis painted black, which answers very well, but the galvanised wire is the best; it needs no painting.—A. B. C.

[The experience at the Chiswick Garden is in favour of wire trellises, as was stated by the Rev. Mr. Berkeley at the last meeting of the Royal Horticultural Society, see page 186.]

CATERPILLARS ON BEDDING PLANTS.

ALLOW me to inform your correspondent, Mr. F. Fowler, that the larva of the Cabbage Moth (*Mamestra Brassicae*), always feeds up, forms an earthen cocoon, and turns to a pupa in the autumn. It never hibernates. It is possible that his larva may have been those of *Mania typica*, which does pass the winter in its larva state, and was rather troublesome in my greenhouse during the early part of this winter; but it is far more probable that the caterpillars he found so destructive were those of *Phlogophora meticulosa*, the Angle Shades Moth. This larva is almost as often dark reddish brown as bright green, and to an uninitiated entomologist, the two varieties would seem to be different species.—H. HARRIS CREWE, Rectory, Drayton-Brauchamp, Tring.

NEW BOOKS.

Handy Book of the Flower Garden. By DAVID THOMSON, Archerfield Gardens. Blackwood & Sons, Edinburgh and London.

THERE are some men who never write upon any subject unless they perceive that relative information is needed, and that they possess such information. Mr. Thomson is one of those men, and the consequence is, that the book before us is thoroughly good. In separate chapters, plants for spring, summer, and autumn decoration are enumerated, and their culture detailed; ornamental-foliaged plants, herbaceous plants, Roses, Annuals, &c., receive a similar consideration, and the whole concludes with chapters on the arrangement of colours, beds, and groups, with seven plans. It is a practical volume, which we recommend to our readers without any reservation.

The Trees of Old England: Sketches of their Aspects, Associations, and Uses. By LEO H. GRIMDON, Lecturer on Botany at the Royal School of Medicine, Manchester, &c. London: F. Pitman.

THIS is one of those books which every one peruses with pleasure. It has for its themes the good, the true, the beauti-

ful, and the useful, as illustrated by the forest trees of our native land. "It has not the slightest pretensions to a scientific character, seeking simply to set forth in a plain and easy manner, some few of the beautiful and refreshing truths connected with the foresters of Old England." An extract which we take at random, will give the best idea of the volume's contents.

"On the left bank of the river, about a mile above Two Bridges, the hillside is heaped with blocks of granite, in the spaces between which are nearly five hundred trees of the Wavy-leaved Oak, but singularly distorted. They are gnarled, knotted, and twisted, seldom more than 10 to 11 feet in height, and with a circumference not exceeding 5 feet, and generally much less. The bark is ragged and interrupted, and extends for the distance of about half a mile. Such a group of trees would not be very remarkable in itself: what renders the scene so extraordinary is that the branches, except at the extremities, and this not always, are completely matted over with a Moss, called by botanists *Anomodon rotundifolium*. In most cases the green covering is from 10 to 12 inches in thickness, though the branch that supports it is not of greater diameter than a child's wrist. The weight is so considerable as to bend the branches downwards, just as we may see the branches of Lilacs and other sapling trees weighed down at Christmas by the gentle deposit on them of abundant snow; and all over the surface of this beautiful coating of vegetable velvet may be discovered, in their season, the lovely little seed capsules, by the produce of which the plant is multiplied. The name given to this singular spot, which seems as if it had been touched by the wand of some botanical enchanter, is Wistman's Wood. It is easy of access, and should be visited by every one who may happen to pass through that part of Devonshire.

"Every old wood and forest shows us Oaks bearing Ferns. The latter are chiefly of the kind called Polypody, or the 'Many-footed,' on account of the numerous lateral leaflets giving the idea of feet, as in a centipede. On those grand old rugged bosses which the Oak is so apt to form, some 10 or 12 feet above our heads, there may often be seen a tuft of this elegant plant, perched completely out of reach, and decked with those gay spangles of bright gold which render the Fern in question so easy of recognition, and attract the eye of the most inquiring. All lovers of nature have been attracted in the first instance to the specialities, by some particular plant or flower, which, holding up its finger, as it were, and beckoning, has allured them into one of those sweet side chapels of the great cathedral, which, when a man has once entered, he never desires to leave. There was a famous fable in olden time of a country in which grew Lotus trees. When travellers entered that country, and tasted of the fruit, they were overpowered with an indefinable and delicious longing to remain there always, not necessarily to be always eating Lotus, but to enjoy the heavenly climate and atmosphere that produced it. That country, with its Lotus trees, has not been blotted out. The fable, like every other true one, is for all time. Living nature, everywhere round about us, is the country of the Lotus, and the fruit is the serene and innocent delight, with innumerable sweet teachings for our intelligence, that comes of our looking at it reverently and lovingly. The beckoning thus given is always remembered with pleasure. Fries, the great German writer upon Fungi, tells us how he was attracted to the study of that class of plants, by the lustre of the crimson Dryads' cup, by botanists called *Peziza coccinea*, which in the earliest days of spring appears on dead branches in damp woods and groves, and resembles an immense acorn chamber of the loveliest coral red."

The Orchid-grower's Manual, Containing Brief Descriptions of Upwards of Seven Hundred Species and Varieties of Orchidaceous Plants, &c. By B. S. WILLIAMS, F.R.H.S., &c.

That this is the third edition, is a sufficient evidence of the acknowledged merit of the work. It is only to be purchased of the author at his Victoria Nursery, Holloway, London.

British Social Wasps: an Introduction to their Anatomy, Physiology, and Architecture, and General Natural History, with Illustrations of the different Species and their Nests. By E. L. ORMEROD, M.D., &c. London: Longmans, Green, and Co.

MANY years ago—in the old coaching times—we were travelling with three ladies, strangers to us, when a scream, and the pointing finger of one of them directed our attention to a live snake issuing from the bonnet of her who sat as our *vis-à-vis*. Singularly enough her name was "Eve," and she calmed us by the assurance, "I always have a pet snake." We were reminded of this by the first sentence of the volume before us—"Wasps have been my holiday companions for many years," and so attached has the author become to his "companions," that he says, "bee-keeping and wasp-keeping are about on a par" so far as profit is concerned! What say you to that, ye thousands of British apianians? But our heroic author goes further and groups wasps among the useful insects. They consume, he says:—

"Rotten wood and garbage of all kinds, and besides these, all the insects that they can master. It will be admitted that they devote

themselves to this part of their duties with great assiduity, making prizes of all flies, spiders, and caterpillars; bees, and even other wasps, not being excepted. It would be very difficult to prove absolutely that wasps have a sensible influence in diminishing the number of flies and of other insects. But it is the conviction of some of those who have paid attention to the subject that this is really the case. Among others, Mr. A. Bryon, F.R.S.E., of Edinburgh, the friend and biographer of the late Sir Thomas Brisbane, has assured me that the practical result of destroying all the wasps on Sir T. Brisbane's estate was, that in two years' time the place was infested, like Egypt, with a plague of flies. At every wasp's nest you might have gathered a handful of the wings of insects; and the flies thrived apace when the wasps were killed."

Let us rejoice Dr. Ormerod's heart by adding that we have often watched wasps preying upon the daddy-longlegs that were sunning themselves upon a wall. The wasp darts at his victim, nips off and absconds with its abdomen, and leaves the winged thorax to scramble away, which it does, apparently as if it had sustained no loss!

Moderate enthusiasm aids to the attainment of excellence, and in the case of Dr. Ormerod has enabled him to produce an excellent book on what most readers will consider an uninviting subject. The volume is very amusing as well as instructive, and we have given it the best of testimonies by reading it.

ORNAMENTAL AND FLOWERING SHRUBS.

(Continued from page 187.)

LAVINIA MOBILIS (Sweet Bay).—Leaves smooth, lanceolate, dark green, sweet-scented; flowers yellowish, in May, followed by purple berries. Requires a sheltered situation. The variety *crispa* has waved leaves, subcylindric narrow leaves, and regains very handsome foliage. Height 12 to 25 feet. Seeds sown in heat, or cuttings in a frame.

LAVANDULA SPICA (Lavender).—Well known, and deserving of a place in every garden on account of the fragrance of its foliage and flowers. 3 feet. Cuttings or slips in spring.

LIGUSTRUM VULGARE SEMPERVIRENS.—Well known, very suitable for plantations shaded by large trees, and good for a screen or hedge. 6 to 8 feet. It is propagated by cuttings in autumn, in the same way as Camellias. There is a yellow-berried variety.

LIGUSTRUM JAPONICUM.—Leaves large, shining; flowers numerous, white, followed by dark purple berries. 6 feet. Seeds and layers.

LIGUSTRUM OVALIFOLIUM, a fine broad-leaved sort. 6 to 10 feet. Layers.

PHILLYREA ANGUSTIFOLIA.—Leaves shining, dark green, very desirable for shrubberies. 10 feet. Layers and cuttings. *P. latifolia* and media are desirable species.

RHAMNUS ALATERNUS LAMPOLUS.—Leaves shining. Of rapid growth and ornamental for shrubberies. Angustifolius with narrow leaves, and the white-variegated variety, are desirable. Cuttings and layers. 10 feet.

RAPHIOLEpis OVATA.—Leaves ovate, shining, dark green, broad; flowers white, in April and May, succeeded by purple berries. It forms a handsome bush. 10 feet. Layers.

ROSMARINUS OFFICINALIS (Rose-mary).—Leaves linear, dark green; foliage scented. Cuttings and layers. 4 feet. Needs a sheltered situation.

RYSCUS RACEMOSUS.—Leaves green; shoots green. Very handsome, and desirable for shady situations. This is the Alexandrian Laurel. Height 4 feet.

RYSCUS ACULEATUS.—Leaves dark green; flowers small, white, on the leaves, succeeded by large red berries. Does well under trees, where it is very fine. 2 to 3 feet. Division.

SEMDIA JAPONICA.—Leaves shining, dark green. Does well in shade, and is very fine in winter on account of its branches of red berries. Cuttings and layers. It will grow where few other shrubs will live, and its foliage contrasts well with the red berries.

SPARTIUM JUNCUM (Spanish Broom).—Leaves lanceolate; shoots dark green; flowers yellow, sweet, in July. Very desirable. 6 to 8 feet. Seeds and cuttings. There is a variety with double flowers.

SPARTIUM MULTIFLORUM (White Portugal Broom).—Shoots deep green; flowers white. Seeds.

FLEX EUROPEUS (Furze).—The double Furze or Gorse is very handsome in early summer. 3 to 6 feet. Should have a sheltered situation. Cuttings. Dry soil.

VIBURNUM TINUS (Laurustinus).—A well-known favourite. Foliage dense and compact; flowers white, tinged with red, produced during mild weather in winter and in spring. It should have a sheltered situation, and will thrive in partial shade, but not in intense gloom. There are several varieties, strictum and latifolium being most hardy. It should be extensively planted; it bears cutting well, and may be pruned after flowering in spring to any shape or size required. Layers and cuttings in autumn or spring, in a warm border or under a hand-glass.

VINCA MAJOR.—Leaves ovate, deep green; flowers blue, in May and successively. Does well under trees. 2 feet. Division, cuttings, and layers. Of trailing habit.

VINCA MAJOR ELEGANTISSIMA.—Gold-variegated leaves; very fine. Cannot be too extensively planted in all situations where a close growth is required, and succeeds under trees. Cuttings.

VINCA MINOR.—Flowers blue. There is a variety with white and another with reddish flowers. Trailing. Does as well as the preceding in shade.

YUCCA GLORIOSA.—Leaves long, deep green; flowers in panicles, white, bell-shaped, in July and later. 5 feet. Suckers.

YUCCA FILAMENTOSA.—Leaves with white threads at the margins; flowers very numerous, on a long flower stem, white, in September. Should have a light deep soil.

YUCCA GLAUDESCENS.—Leaves often 2 feet in length, glaucous, lanceolate, numerous; in autumn or late in summer. Suckers.

DECIDUOUS SHRUBS.

AMELANCHIER BOTRYAPUM (Snowy Mespilus).—Flowers white, numerous, and highly ornamental, in April and May. Height 12 to 15 feet. Seeds and grafting.

AMELANCHIER VULGARIS.—Flowers white, very numerous, highly ornamental. April. Seeds and grafting. 10 to 15 feet.

AMYGDALUS NANA (Dwarf Almond).—Flowers rose, numerous, very ornamental. March and April. 6 feet. Requires a warm situation. Budding on the Plum. The double variety is very ornamental; it has rose-coloured flowers. There is also a double-flowering variety with white flowers.

AMYGDALUS ORIENTALIS.—Flowers rose; leaves silvery. Requires a sheltered situation and light soil. March and April. 10 feet.

AMYGDALUS PERSICA FLORE-PLENO (Double-flowering Peach).—Flowers rose, very numerous. Highly ornamental whether trained as a pyramid or standard; it should have a warm situation and dry soil. 10 feet. There are double-flowering varieties with carnation, white, crimson, and rose-coloured flowers, all admirable for forcing and early flowering. They are propagated by budding on the Plum or Almond. They flower at the same time as Peach trees, in March and April.

ANORPHE FRUTICOSA.—Flowers purple; in July and August. A desirable shrub with pinnated leaves. 10 feet. Layers and cuttings.

ARALIA SPINOSA.—Flowers whitish, in panicles; leaves tri-pinnate, large, and very handsome. It requires a light open soil, but likes moisture. Flowers in August or September. It should have protection in winter as the stems are liable to injury by severe frosts, and a band of straw ought to be wrapped round the stem from the ground upwards. 6 to 10 feet. Seeds sown in heat, suckers, and cuttings of the shoots and roots in sandy soil and slight bottom heat.

BERBERIS VULGARIS.—Flowers yellow, succeeded by violet-coloured berries in autumn. Does well in the shade, and forms a close bush, being ornamental in foliage. The fruit make a very good preserve. Besides this (the common Barberry), there are varieties with white and stoneless fruit. 6 to 10 feet. Seeds, layers, and suckers.

CALYCANTHUS FLORIDUS (American Allspice).—Flowers brown, very highly scented. It flowers in June and July. 6 feet. Layers and suckers.

CALYCANTHUS MACROPHYLLUS.—Flowers large, reddish brown, very sweet, and admirably suited for a north wall or aspect, where it flowers beautifully for the greater part of the summer. Layers and cuttings.

CALOPHACA VOLGARICA.—Flowers yellow, produced in profusion in May or June. 3 to 4 feet. Seeds.

CARAGANA FRUTESCENS.—Flowers yellow, in May. If grafted standard high on *C. arborescens* it forms a pendulous head. 8 to 10 feet. Seeds.

CARAGANA PYGMÆA.—Flowers yellow, small. A low-growing spreading shrub, which if grafted standard high on *C. arborescens* forms a compact head, and is very ornamental in flower gardens. 3 feet.

CARAGANA CHAMLAGU.—Flowers yellow, large. May and June. Plant spreading and effective when grafted standard high on *C. arborescens*. 4 feet. Seeds.

CHIMONANTHUS FRAGRANS.—Flowers pale yellow, small, remarkably fragrant, and numerous, produced from December to February. It should be planted against a wall with a southern aspect, and have protection from frost, except in warm situations. Luteous with flowers of a deeper yellow, and grandiflorous with larger flowers, are not so fragrant. 6 to 8 feet. Layers.

CHIONANTHUS VIRGINICA.—Flowers white, in long racemes, numerous, contrasting well with the bold lanceolate leaves. Requires a well-drained, yet moist loamy soil. 10 to 12 feet. Seeds in gentle heat, and layers.

COLUTEA ALBORESCENS.—Flowers yellow, numerous produced throughout the summer. Desirable on account of its rapid growth. 10 feet. Seeds; also cuttings of the roots.

CORNUS SANGUINEA (Dogwood).—Flowers white, succeeded by a profusion of purple berries. The shoots are red, and the variety with variegated leaves is very ornamental. Succeeds admirably in the shade, and in strong moist soil. 12 feet. Seeds and layers.

CORNUS ALBA.—Flowers white, succeeded by white berries. Shoots bright red, very handsome. 8 to 10 feet. Layers.

CORYLUS PURPUREA.—Ornamental on account of its deep purple leaves.

CORYLUS AVELLANA LACINIATA.—Noticeable on account of its cut leaves. Suckers and layers. 10 feet.

CYDONIA JAPONICA.—Flowers red or scarlet, in March, April, and May. A beautiful shrub, very suitable for a wall. 1 to 6 feet. Layers,

suckers, and cuttings of the roots. The variety with white flowers is not nearly so handsome, but that called *principes* I think very fine. *Rosea* is desirable on account of its paler flowers.

CYTISUS PURPUREUS.—Flowers purple, very ornamental, and numerous produced from May to August. Of procumbent habit. *C. elongatus* and *supinus*, both with yellow flowers, and *C. purpureus* already named, form very handsome pendulous heads when grafted on the *Laburnum*. Seeds and layers.—G. ARBEEY.

(To be continued.)

NOTES AND GLEANINGS.

THE subjects which the Fruit Committee of the Royal Horticultural Society intend to investigate this season at Chiswick are Peas, Kidney Beans, Beets, Onions, Leeks, and Broccoliis. Seedsmen who possess novelties of any or all of these kinds of vegetables are invited to send seeds of them as speedily as possible. The Floral Committee intend directing their attention to the varieties of Everlastings, annual and perennial, new Annuals, Fuchsias, Violets, Pelargoniums, and Heliotropiums. The Chiswick Board have decided on making a collection of all the species and varieties of Liliun, and to secure for the garden as complete an illustration of this beautiful genus as it is possible to obtain, and the Society will be obliged to all who will aid in this desirable object. All packages should be addressed to "The Superintendent, Royal Horticultural Society's Garden, Chiswick, London, W."

A FEW amateur and professional gardeners, desirous to forward the cause of horticultural science, have resolved to hold a conversazione on an extended scale at Darlington, combining the reading of short papers, should time permit, and a microscopic exhibition. Joseph Pease, Esq., Southend, Darlington, has given his patronage, and also most liberally provides two well-known lecturers—viz., Messrs. Wheeler, of London, and Censable, of Tynemouth, to conduct and explain that part of the proceedings belonging to the microscope and lantern. The Committee will be obliged by specimen Apples of the variety considered by the sender most suitable for spring use in his county; also, by small hand bouquets, showing more particularly the flowers most valued by the sender at this season of the year. The proceedings begin on the 24th of the present month, at 5 p.m. Particulars may be obtained from Mr. John Richardson, Hon. Sec., Southend Gardens, Darlington, Durham.

It is our painful duty to announce the death of Mr. CHARLES WILLIAM CROCKER, which took place at Torquay, after a long illness, on the 19th of February, in the thirty-fifth year of his age. The deceased had acquired some distinction in his native city (Chichester), for his various acquirements; and among other pursuits he had attained a reputation as a literary correspondent to various periodicals and newspapers. For some years past he had contributed to the local newspapers, THE COTTAGE GARDENER, &c. He took great interest in the Chichester Gardeners' Improvement Society, of which he was for some years the President, and frequently lectured before its members on botanical and horticultural subjects. He was for many years a member of the Committees of the Horticultural Society, of the Literary Society and Mechanics' Institute, and of the Working Men's Club of the city, and worked zealously for each. He was of late years one of the officials of the cathedral, and his acquirements rendered him a desirable eicerone to its numerous visitors, and with much tact he used to direct their attention to the beauties of the building and its interesting monuments. He published in 1866 a very useful little work, entitled, "The Visitor's Handbook to Chichester: a brief account of the history and antiquities of the city, a complete description of the cathedral church, with a notice of remarkable places in the vicinity."

The deceased was constantly engaged in the conscientious discharge of whatsoever his hand found to do. He was the son of Charles Crocker, the poet. He was formerly a pupil at Oliver Whitby's school, where he availed himself of the opportunity of laying a solid foundation of knowledge, which helped him much in his studies in after-life. When his time came to leave this establishment, he engaged himself in the service of the late Mr. Silverlock as gardener. During his hours of leisure Mr. Crocker was a constant evening visitor to the Chichester Museum, and studied most assiduously under the guidance of Mr. Hills, the excellent curator, and he amassed a large amount of valuable knowledge in the sciences of mineralogy, geology, &c. From Mr. Silverlock's he went to Leigh Park, and was under Mr. Scott, who then superintended its beautiful gardens

and pleasure grounds. He subsequently held a responsible post at Kew Gardens, and after a time proceeded thence to the summer residence of the Crown Princess of Prussia (Princess Royal of England), near Berlin, a graphic description of which he wrote for the columns of the *Brighton Herald*. On his return to England he again resumed his post at Kew, but, on finding the arduous duties attached to his employment were undermining his health, he returned to his native city, and employed himself usefully and honourably up to within a period of three months before his decease.

WORK FOR THE WEEK.

KITCHEN GARDEN.

As soon as the soil is dry all crops in rows should have the ground well stirred between them, and this should be done three or four times before the end of April. If you are near a farmyard or common sewer, you need not wait for manure to apply between the rows of Spinach, Cabbages, and similar crops. Now is the best time to begin to apply liquid manure to standing crops. A peck or two of soot will make a good liquid manure if no better is at hand. *Borecole*, or *Kale*, to secure heavy crops of this hardy winter vegetable, a deep soil is essential, and the ground should be trenched 2 feet deep, and be liberally manured. For the main crops sow now, covering the seeds thinly and evenly. *Cauliflowers*, sow the Asiatic and Stadtholder now or early in April on an open border. The soil for this vegetable can neither be too rich nor too highly cultivated. *Capsicums* and *Chilies*, sow in well-drained pots filled with light sandy soil, and placed in a Cucumber frame, or wherever a temperature of about 65° is maintained. Cover the seeds to the depth of about half an inch, and keep the surface constantly moist until the plants appear. *Love Apple*, or *Tomato*, sow seed and treat as recommended for Capsicums. When the plants are about 2 inches high place them in 5-inch pots, putting two plants in each, and replace them in heat; the plants to be well watered and kept near the glass, so as to promote strong sturdy growth. *Lettuce*, for successional crops sow now in beds of well-pulverised soil, and at intervals of about a fortnight until the end of July. Make the surface of the beds firm, sow thinly, and cover the seeds lightly with fine soil. *Potatoes*, it has been proved that early planting is the best preventive of the attacks of disease, for as the crop sooner arrives at maturity it frequently escapes altogether, or suffers comparatively little. Plant any of the good sorts as soon as the ground is in good working condition. The sets of the late kinds should be planted 5 or 6 inches deep, leaving the soil over them as open and loose as possible. They will require at least 2 feet from row to row. I can recommend Dancer's Red Regent as very productive and comparatively free from disease.

FRUIT GARDEN.

It would be a good plan to take one-third of the trees annually, and paint them over their trunks and main branches with thick lime, with a little soot dusted in it to take off the white glare of the lime. If any of the standards showed signs of moss or insects under this triennial dressing, they should be painted over more frequently, while all the stone fruit trees on the walls should about this time be gone over every year. Have coverings ready for the Peach, but do not use them till there is an actual necessity for it.

FLOWER GARDEN.

If it is intended to make any addition of new shrubs or trees in this department, they should be planted immediately. *Aracaria imbricata* is one of the noblest plants we have, and many of the Cedars, Pinuses, and Cypresses, to say nothing of *Magnolias*, are very beautiful. Pinuses suffer more from the destruction of the early spring growth than from any other cause; therefore endeavour to check them by admitting a current of cold air from the north side, and by keeping the plants shaded on sunny days. *Polyanthuses* are now throwing out fibres round the neck of the plant and growing fast. If increase is more an object than bloom, they may be parted to advantage now. Tulips ought to be protected from heavy soaking rains, as well as sharp frosty winds, which we may yet expect. The best way to sow annuals is first to loosen the earth where it is intended to place them, avoiding raking the borders at present unless the ground is very light, then make a slight drill by pressing the rim of a 32-sized pot upon it, sow the seeds very thinly, and cover with loam and leaf mould finely sifted, and in about equal proportions.

GREENHOUSE AND CONSERVATORY.

The Azaleas have a double demand on their food—to maintain their flowers, and to make their young wood; they must, therefore, be well supplied with moisture at the roots. Pelargoniums at this season remain so long in flower that they are sure to have the green fly on them. Remove them and every other infested plant to be smoked elsewhere, if the conservatory is attached to the living-rooms. Climbers will now begin to spread over the house, and will require particular care in training them regularly at first. *Stephanotis floribunda* will survive a mild winter in a night temperature as low as 45°. Little syringing should be done here on account of the bloom; water must, therefore, be poured on the paths and any spare places to keep the atmosphere moist and cool. See that insects are kept down, and that plants have sufficient room. Specimen plants are easily injured at this time if they are crowded together. All the plants brought in for the sake of their flowers only should be removed as soon as they are out of bloom. Some of the more hardy and common plants in the greenhouse might now be removed to some sheltered place, in order to give more room to the finer kinds. Young plants in small pots might now be potted on the one-shift system; but for this it is essential that their roots be not much matted, and that they be in a growing state. The only disadvantage in this system is, that after a few years the soil will subside too much in the pot, and many delicate plants will not bear the pots to be filled up again. The best remedy against this is to place an inverted pot over the drainage, as is often done with Orchids, and to have it so adjusted that when you place the small ball at the bottom of it, the top of the ball will be level with the top of the large pot. A small Heath thus treated may safely be trusted in the largest pot. The collar of the plant always remains at the level at which it was placed.

STOVE.

Keep up a moist heat of 75° or 80°, and let the house be rather close, in order to encourage newly-potted plants. Proceed with the potting of the different tribes as before recommended. Watch carefully over seedlings, and put in cuttings as early as possible of those plants you wish to increase. Now is the best time to strike cuttings.

FORCING PIT.

Keep every part of this pit full of plants and cuttings. All the species of Jasmine force well. If kept under-potted and their young wood constantly stopped in the growing season, they form loose bushes and lose their climbing habit; they are then more manageable for forcing. All American plants require large quantities of water when forced. Sow a few seeds of Balsams, Cockscombs, Browallias, Thunbergias, &c.

PITS AND FRAMES.

Many of the hardier plants here may now be removed to temporary shelter to make room for others from the greenhouse, and for newly-potted plants for the flower garden. Florists' flowers require more room also—in short, every tribe now should be attended to, according to the wants and wishes of the owner. Among the first work to be attended to, especially when a large stock is required for flower-garden decoration, is the propagation of Chrysanthemums. Pot Tuberose in 48-sized pots in turfy soil, and place them in a gentle warmth until they begin to grow. They are useful for setting among plants near the windows, or for the decoration of the hall or drawing-room.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Parsnips.—Took the opportunity of a dry day and the soil being in a favourable condition to sow the main crop of this useful vegetable, almost the only one we care about sowing in our stiff soil early in March. No tuberous-rooted crop requires more time to come to thorough perfection, and its richness of flavour is greatly owing to the time it has had to perfect its peculiar properties. Young Carrots are in most people's estimation very sweet and desirable—so much so, that at one time we continued sowing monthly from the last fortnight of March to the end of June, besides several sowings in heat from December to the end of February; but we never met with a lover of vegetables that cared much for young Parsnips, and therefore the thinnings are of little importance in the kitchen. We prefer the old Hollow-crowned, and though we have tried

a number of sorts advertised with very high characters, we never found them on the whole to beat it.

We have sown in rows 18 inches apart this season in the usual way, but in land at all heavy (and the plan might be thought worthy of adoption by amateurs), we have marked out the rows, and then with a strong dibble made deep holes 6 inches apart, filled these with fresh very sandy loam, and in each hole deposited three or four seeds, the plants from which will be finally thinned out to the best one. By this plan we have obtained straight roots of extraordinary size. We may also mention that this season we have sown on a piece of ground from which Asparagus had been taken for forcing; and though the best and richest soil from repeated surface-dressings of the Asparagus, owing to trenching, would be at the bottom, still the surface soil would be richer than we like for these roots and Carrots. When the rotation will permit of it we prefer as poor a piece of ground as we have, manured on the surface; the manure trenched down to the bottom, the ground ridged, and the ridges several times turned, but not so deeply as to reach the manure, so that when the seed is sown there shall be an encumbrance for the seedlings to send their roots straight down—just as the roots of an Ash or a Lime will travel a long way, as if by a sort of instinct, to reach the moisture of a well.

Carrots.—Sowed a few rows of the Early Horn, as, if they succeed, they will be useful, and if they partially fail, the loss will be little. We are more particular in having the ground well prepared for this crop than in sowing early. In general we find the end of March and the beginning of April the most suitable times. There is then less danger of checks, and the seedlings become strong and healthy at once. It is true the seeds will take no harm from lying in the ground, it is the young seedlings that suffer from sudden frosts and extreme changes in the weather.

Onions.—We sowed a lot under protection for salads, and, perhaps, planting out a few; but the main out-door crop we will not sow for a week or two, unless the weather should be very favourable, and at present we expect rain, if not snow. We will use our Celery ground, on which the Celery was grown in beds, as we could not afford space for having it in rows. Last season we had not a single head which had run to seed. We trenched and ridged the ground crosswise, which enabled us equally to distribute the manure at the bottom of the Celery beds all over the piece, the beds running north and south. This plan, though effectual in equalising the manure over the piece, was not a good one for airing the ground equally and well, so a dry day was chosen for levelling the ground roughly, and then ridging it up one spit deep in ridges lying north and south, that the sun might act on both sides of the ridge equally. We will most likely turn these ridges roughly again, so as to air and sweeten the ground, and then dig level, and some fine day have the ground trodden, raked fine, and the Onions sown in rows; though in stiff ground it is a good plan to sow in rows in beds, with alleys between them. For amateurs this is also the neatest plan, as the neatly-edged beds are pleasant to the eye; but in general we sow the piece in rows from 9 to 12 inches apart, and, unless the ground is very dry, we scatter a little fine soil over the seeds in the rows, and when finished, draw a light wooden roller over the ground, passing a heavier roller over it as the seedlings begin to peep above the surface.

Cucumbers.—Planted out a lot more in frames and pits. A two-light box served to produce us strong early plants of Cucumbers and Melons, and were the heat to be bestowed on that tribe alone, there is no other method by which good plants can be obtained so economically. The same frame was used for flower and other seeds before the Cucumbers wanted the room.

Potatoes.—Besides planting out, put several sorts, chiefly new kinds, not sprouting, on a bed in the Mushroom house, that they might root and show shoots 2 or 3 inches in length before planting. If these are turned out in a sunny day, and the warm surface soil placed round the roots and stems, they will receive no check, and come considerably earlier than sets planted at once.

Leeks.—When these are wanted early and large, the seed should now be sown thinly in a bed, and receive a little protection from boughs until well up. When the seed is sown thinly the plants are stronger for planting out. It is easy having these healthy vegetables large after this time. The difficulty with us has been to have large specimens in winter.

Sowed successions of small salading, Radishes, Cauliflowers, and a few Cabbages under protection. We are using spring-sown Radishes, as those that stood the winter under protection are now much harder and less crisp.

We will prepare ground for Asparagus, Sea-kale, Artichokes, &c., as soon as possible. Globe and Jerusalem Artichokes cannot be planted too soon. The latter will last for years; but when ground and time can be spared, we always think the tubers sweetest and best when fresh planted every year like Potatoes. If the weather continue cold, beginners may bear in mind that having the ground in good condition is more important than very early sowing.

FRUIT GARDEN.

Much the same as in last and previous weeks; a press of other matter has thrown us behind in this department, but we must finish our out-door pruning as soon as possible, and must take some simple means for protecting Apricots and Peaches. As for the latter, the crop is now becoming so uncertain out of doors, and fine trees run such risks, not only of having the crops destroyed, but also of the trees being so injured by severe frosts and sudden changes, that we trust that most people who have gardens of their own will cover their Peach walls with a cheap glass construction, which will soon pay itself by the saving effected in the labour and expense of protection, and, as a general rule, make sure of a crop with but little trouble. These cheap fixed glass-roofed houses, as adopted by Mr. Rivers, Messrs. Lane, and many others, place fine fruit within the reach of those having but a small garden, and with common care success is almost certain. Most likely we will use laurel or beech twigs for protection. For a constant covering nothing is better than woollen, or even the thin Nottingham netting. For a moveable protection nothing is better than stout calico, and the great object is to use it for retarding as well as for protecting, by keeping it on during sunny days before the bloom opens, and taking it off on cold days and nights. This also permits of more reciprocal root action. After the bloom opens the practice must be reversed, and the bloom have all the fine weather, and be protected from the cold.

ORNAMENTAL DEPARTMENT.

Nearly finished planting for present cover and future timber, and it is well to have all such work done by March.

Warm Sheds.—These, we trust, will soon be an essential requisite in every garden of note. We have no such regularly warmed place, but we have several furnaces covered over with sheds, and in winter and spring these are tolerably comfortable, but even then not quite so suitable as a working shop heated by hot water, which can easily be done where a boiler is at work in the vicinity. Our nurserymen are finding that such comfort is conducive to work being done economically. When we called on Mr. John Fells, at Hitchen, lately, whilst noticing the improvements in his houses, &c., we were particularly pleased to see a large workshop heated by hot water, where the men might work comfortably in stormy, rainy weather in winter. Mr. Fells stated that the hot-water pipes had been a most profitable investment, for the men with comfort to themselves did much more work, and did it much better.

Cleaned and swept most of the pleasure grounds preparatory to a good rolling of the lawn. We will cut the sides of walks as soon as possible, trim and regulate herbaceous plants, and prune Roses as soon as we can. We will also turn and re-turn flower beds. Potted Fuchsias, Pelargoniums, Ferns, and other plants; fertilised blooms of Chinese Primulas, as the 2s. 6d. and 3s. 6d. packets of our florists yearly become less and less. Forced Hyacinths and other bulbs are getting towards their termination; shrubs and Roses will take their place. Pricked-off in little boxes Lobelias, Petunias, &c. Sowed numbers of flower seeds, as Perilla, Amaranthus, and Lobelias, in a hotbed, and, in order to shade, whitened the glass inside, as that will obviate the necessity of much watering until the seedlings are up, as the pots were prepared as described last week. Put in lots of Verbena, Centaurea, and other cuttings. Placed some Verbenas on which some green fly appeared in a box by themselves, and smoked them; and to save future trouble drew the cuttings as made through weak tobacco water, and would have little difficulty now but for want of room in which to place the multitudes of little plants wanting attention.—R. F.

TRADE CATALOGUES RECEIVED.

Carter & Co., High Holborn, London, W.C. — *Carter's Farmers' Calendar* for 1868.

William Paul, Waltham Cross, London, N.—*Spring Catalogue of New Roses, Pelargoniums, Hollyhocks, &c.*

Charles Huber & Co., Hyères.—*Catalogue Général pour l'Automne 1867, et le Printemps 1868.*

COVENT GARDEN MARKET.—MARCH 11.

FOREIGN importations are heavy and prices receding. The best English produce maintains last week's quotations, owing to the supply not being so liberal. Pines and hothouse Grapes are scarcely sufficient for the demand. Of the former we have had some good specimens from St. Michael's, weighing from 3 to 6 lbs. each.

TO CORRESPONDENTS.

BOOKS (*Tan*).—"The Garden Manual" will suit you. You can have it free by post from our office if you enclose twenty postage stamps with your address. (*Alpha*).—The price of the work you name is 31s. 6d.

ARISTOCLES (*Ignoramus*).—Mr. Beaton died before he had obtained any satisfactory results from his experiments with these flowers.

ADDRESS (*H. K.*).—We do not know the address of the gentleman to whom you refer.

GLASS COVERING FOR WALL.—"C. R." wishes "BATH" would state from whom he obtained the covering he mentioned.

IMPROVED MELVILLE'S VARIEGATED BROCCOLI.—At page 167, February 27th, this heading was misprinted "Broccoli."

PELAGONIS HUNG UP IN A ROOM (*H. A.*).—You should now pot the plants hung up by their roots, using dry sandy loam, and by degrees bring it into a moist state. The plants may be placed in a greenhouse window, in any house where there is a gentle heat, or in a hotbed; but if placed in the latter they must be carefully watered until they begin to grow, otherwise they may damp off.

SOVING AUCUBA BERRIES (*Aucuba*).—The berries should not be dried, but sown at once in a compost of two-thirds loam and one-third leaf-mould. They may be placed in a mild hotbed, but will succeed in a greenhouse. When the seedlings appear, and have grown a little, the male plants may be distinguished from the female, but only by those conversant with them. You will have to wait until they are of a size fit for flowering and producing berries are you will be able to distinguish the male from the female plants. The berry-bearing plants are, of course, the female plants. If placed near them, the male will fertilise the female naturally, but to make sure it is well to do so artificially. With good treatment the plants will produce berries the second year, but they vary considerably in this respect. They generally have berries by the third year.

SELECT SUBTROPICAL PLANTS (*St. Dem's*).—We are not sure whether the bed above that is 5 feet by 31 feet, or if that is the size of each of the three steps; if the latter, then *Wigandia caracasana*, *Ricinus borbonensis*, and *Striped Maize* would do for A; *Ricinus Obermanni*, *Ricinus sanguineus*, and *Canna Finckmanni* and *Worcesterii* would do for B. Your plants of *Cakile* *cuneifolia* would do for C, along with *Anacardium mitchellii*, *Anacardium trielori*, *Caribaea benedictus*, and *Perilla nankinensis*, with an edging of *Cineraria maritima* or *Centaurea*. If we mistake let us know, and also if you wish to raise from seed, or obtain plants.

PLANTING VINES (*D. M.*).—Do not turn the Vines out of No. 12 pots if you wish to have a crop from them this season. Top-dress, and thus give nourishment. If your Vines were to be permanent shake the soil away and spread the roots on the border.

VINES WITH ROOTS TOO DEEP (*Boonier*).—We have referred to the answer given respecting your Vines at page 15, and no doubt it was the best under the circumstances, though we do not clearly recollect all these now. In answer to your inquiries of this week, we would not advise you to dig down 8 or 10 feet after the roots of these old Vines, nor to attempt to raise them near the surface. The other plan proposed—viz., to dig down 4 or 5 feet and place fresh compost round the stems in order to encourage roots from the stem, adding compost year by year, will only be a palliative. Presuming that these old Vines do bear a little, we would let their roots alone; and if you can go down 30 inches, or partly to that depth, and make the border that depth by raising it to the wall plate, then we would remove the surface soil as deeply as possible, add fresh compost thinly as advised in page 15, on that place 3 inches of concrete, and from 6 to 9 inches of rubble, and on that make, after securing drainage,

a new border 1 foot wide. To it we would plant young Vines, which will be much better than raising the old Vines; as the young Vines grow out under the old ones, and add 18 inches every year to the width of the border after the second year. This will be the most effectual and the simplest plan.

PLANTING FIG TREES IN A PEACH HOUSE (*T. S.*).—Were we doing what you propose—planting Fig trees on the back wall of a Peach house, we would have a drain and 6 inches of open rubble, then a depth of from 20 to 21 inches of soil, and a wall below the surface to confine the roots to 30 inches in width. We have had them good with a width of from 24 to 27 inches; but if there is room, 30 inches will, perhaps, be better.

CUCUMBERS IN A FLUE-HEATED PIT (*J. B.*).—To make the most of your flue beneath the hotbed of leaves, make a rough chamber over the flue, with openings from that chamber into the atmosphere of the pit. You can regulate your heat then at will with plugs to these openings. It is not safe to have a bed of leaves over and round the flue, and when the leaves are dried they will keep the heat from ascending.

SOILS (*An Old Subscriber*).—The darker soil from adjoining the river is rich alluvial soil, requiring nothing but thorough draining, probably, to render it fully remunerative if cultivated. The other contains abundance of vegetable fibres and rootlets, but is not sufficiently siliceous of them to render it fit for food, nor is the earthy portion sufficiently siliceous to fit it for potting purposes.
